28. **Death Following Scopolamin-Morphin Anesthesia.**—Sexton's patient, aged 47, had been in poor health for five years, principally on account of excessive bleeding from the uterus. A diagnosis of fibroid was made and operation was advised. The patient was anemic and had a weak heart, but otherwise presented no evidence of disease, except of the uterus and ovary. She was prepared for operation as usual, and at 7:30 a. m. a hypodermic of scopolamin hydrobromate, 1/100 grain, and morphin sulphate, 1/6 grain, was given. The patient was sound asleep in fifteen minutes. At 8 a. m. she was found unconscious, slightly cyanosed, pulse 120 and throbbing, respiration 20 but very shallow, abdominal muscles and intercostals rigid, so that it was impossible to compress the lower chest and epigastria. The muscles were contracted markedly. The jaw dropped, the mouth was open, and the eyeballs were turned up. All efforts at resuscitation failed and the patient died at 9:15 a. m. without the least response to stimulants, pain, heat, flagellations or changing posture.

31 *Technic Employed in 100 Laparotomies with the View of Restricting the Employment of Drainage. L. J. Hammond, Philadelphia.

30. **Photometric Method for Case Records.**—To insure convenience and accuracy of handling and economy of time, expense and storage, Fitz has devised a method for photographically recording deformities. The method is briefly as follows: 1. The focus of the lens is adjusted for such selected image sizes of the subject as will give the desired ratios of size between subject and image (such as 6 = 100, 10 = 100, 14 = 100, 20 = 100, etc.). These foci and the corresponding distances of the subject from the camera are marked on the adjusting part of the camera or lens so that the focus can be instantly secured by merely setting an index to a mark and adjusting the patient's distance by means of a graduated tape or knotted string, and the photographs taken in the exact ratio without any delay for focusing or other adjustment. 2. The camera is arranged so that it will take three or four photographs of the same individual in different aspects on the same plate, thereby avoiding confusion in labelling and loss of identity of the several photographs. 3. An identifying number is photographed with each subject and absolutely identifies every photograph. 4. A transparent scale is made, based on the ratios of subject size to the image size selected for records, by which the photographic images may be measured as to any dimension, asymmetry or deformity, directly in inches or centimeters, as if one were measuring the patient himself, by the application of the scale to the face of the photograph. The apparatus employed and the methods of its use are described fully.

31. **Drainage and Laparotomy.**—Hammond's experience has convinced him of the worthlessness of the gauze drain in any shape or form, but he considers the gauze tampons, as recommended by Mickulicz, a rational means of avoiding infection of the neighboring viscera. Its value, however, is but temporary, and its presence as a foreign body not only lessens the power of resistance of the peritoneum, but goes far toward keeping up shock, encourages the excessive formation of adhesions, and is the commonest of all causes of about all of the postoperative hernias. The argument that is used by some, that gauze drainage is useful because Nature builds a wall around the infected area, can be logically employed as an argument against its use at all, as the fact that Nature does not shut out from communication with the general peritoneal cavity shows clearly its utter worthlessness.

36. **Fractures of the Head and Radius.**—Thomas concludes that the skiagraph is not infallible in the diagnosis of the uncomplicated fractures of the radial head. The fragments are frequently so closely approximated by an intact orbicular ligament that the line of fracture may fail to show, especially if the place is an obscure one, or if the rays are directed in an incorrect plane. The fracture of the radial head is always partly and frequently entirely intracapsular, except for the thin attachment of the capsule to the lower edge of the fragment. This attachment probably furnishes an ample blood supply for the nutrition of the detached fragment, even if nonunion occurs. Except in very rare cases, such a fragment will not become a movable body in the joint, in the ordinary sense, since the orbicular ligament, the irregularity in the fractured surfaces, and the attachment of the fragment below will prevent movement of it. The part of the head which is broken off in the usual fall on the hand is anterior at the time of the fall; but, according to the later position of the forearm, may occupy any position within the arc of rotation of the forearm, which is approximately 180 degrees. Instead of being an exceedingly rare fracture, as hitherto believed, it is a common one, its peculiarly obscure nature having rendered it especially difficult of recognition. There are more cases of this fracture, represented by skiagraphs, in the hands of a few skiagraphers in Philadelphia (55), than Thomas could find after a thorough search of the literature (48), making a total of 103. Fractures of the neck of the radius are also common

and are usually associated with fractures of the head. They are frequently impacted, and are due to the same cause as the usual fractures of the head, i. e., to a fall on the hand with the elbow extended. Fractures of the radial head are frequently associated with posterior dislocations of the forearm bones at the elbow and with fractures of the coronoid process. In the usual skiagraph of a posterior dislocation of the elbow, showing a lateral view, the head of the radius is largely obscured by the ulna, and sometimes, also, by the condyles of the humerus; so that this fracture is probably often overlooked in such cases. In a fall on the hand the ground acts as a resisting body. The force is from above, the momentum of the falling body being exerted through the bones of the upper extremity. In extension of the elbow, only the anterior surface of the radial head is in contact with the capitellum, and, as the force is transmitted to the ground chiefly through the radius, this part of the radial head receives the brunt of the force and is frequently broken off. In an uncomplicated case, with distinct crepitus, the diagnosis will easily be made, providing ordinary care is taken in localizing the injury, even without a skiagraph. When available, however, the *x*-ray should always be employed. Severe complications at or near the elbow may render the diagnosis difficult, but the *x*-ray picture, if properly taken, should settle the question.

46 Roentgen Pictures in Orthopedic Surgery. H. O. Feiss, Cleveland.
47 Typhoid Fever, with Special Reference to Treatment. J. B. Woodworth, Delaware, Ohio.

40. *Surgical Pathology of Mammary Tumors.*—Stone discusses particularly the class of true neoplasms comprising 100 cases. Of this number 79 per cent. were carcinomata of some kind, 5 per cent. were sarcomata, 15 per cent. were adenofibromata (four of which showed evidence of beginning carcinoma) and one patient had tuberculosis of the breast. Therefore, the malignancy of the entire series is 88 per cent.

42. **Analysis of Ninety-one Cases of Breast Cancer.**—The mean age of Crile's patients was 49; the oldest, 71; the youngest, 24; 64 per cent. occurred in patients between the ages of 40 and 60. Fourteen per cent. had never married; 35 per cent. had not borne children. In but 11 per cent. was there a distinct history of lactation complications of importance. In 33 per cent. there was retraction of the nipple. In 17 per cent. there was a discharge from the nipple. In 78 cases it was found that 37 per cent. had a definite hereditary history of malignant tumors. In 94 per cent. the disease was first discovered as a tumor, 67 per cent. of which were painless. In 6 per cent. the first symptom was purely subjective. The mean known duration of the tumor was 11 months; the greatest, 24 years; the least, 2 days. The right breast was involved in 54 per cent.; the left in 46 per cent. Dividing the breast into a central portion and four quadrants, the frequency of location is as follows: Upper outer, central, upper inner, lower outer, lower inner. In the upper hemisphere the tumor appeared precisely four times as frequently as in the lower. There were 61 cases of scirrhus, 9 of adenocarcinoma, 7 of medullary and 3 of alveolar carcinoma, 2 cases each of cancer cyst and carcinoma simplex and 1 case each of perithelioma, sarcoma, and epithelioma, and 4 cases of cancer. For the purpose of clinical study, the cases have been tabulated in three groups: The favorable, which includes those in which the breast tissue only was involved; unfavorable, including those in which there was local or regional extension, but not clearly without operative chance; and palliative, which includes those patients operated on for relief of intolerable local conditions without hope of ultimate cure. Of the 91 cases, 87 were classified as favorable, unfavorable or palliative. Of this number, 53 were favorable, 25 unfavorable, and 9 palliative. This classification was made on the clinical evidence prior to the operation, entirely independent of the later pathologic findings. In this series there was no immediate operative mortality. Up to the present time there have been but two instances of local recurrence of the disease. Deaths from the disease were due to metastases in the thorax, in the liver, the kidneys, the long bones, peritoneal cavity, pelvic organs, vertebral column, the stomach, and opposite axilla. In several instances metastasis occurred after the three-year period. Of the patients in the palliative group none is living; of the unfavorable group 14 per cent. are living; of the favorable group 80 per cent. are living without evidence of the disease. The surgical technic employed was essentially that described by Halsted.

50. **Lavage of Renal Pelvis.**—Johnson is of the opinion that lavage of the kidney is not alone justifiable, but is a procedure whose importance demands recognition from the entire medical profession. Patience, gentleness and experience are necessary attributes in the successful application of this procedure. Lithemia is more quickly eradicated when, in addition to the usal treatment, lavage of the kidney is employed. Pyelitis is a condition that should be recognized at any stage as a danger signal and promptly treated. If possible, the cause should be ascertained and removed. Very mild cases require only rest, and the administration of salol or hexamethylenamin (urotropin) for all others, catheterization and irrigation with boracic acid or silver salt solutions once or twice weekly are indicated. Pyelonephritis may be treated in the same manner with similar agents. Ureteritis will heal under lavage with at first soothing and later mildly stimulating fluids. Chronic parenchymatous nephritis can be alleviated, and in certain phases cured, by proper irrigation combined with appropriate diet and internal medicaments; other forms of nephritis also are amenable in a degree to lavage.

51. **Anesthetic Impotence.**—Robbins reports an unusual case of impotence occurring in an able-bodied man, aged 36. The patient denied any venereal disease or other serious ailment. He never had any impelling desire of a sexual nature. Never has he had any temptation to masturbation or to sexual intercourse. Never has he had any seminal emission, except at night, and these have occurred since puberty at intervals of three or four weeks, and occasionally three or four times in one week. The cause has been looked on as psychic, but this explanation scarcely harmonizes with the fact that never from puberty has the patient had a normal sexual impulse, never felt any desire or temptation to masturbation and never experienced any frictional excitation. The only basis on which Robbins explains this condition is that of lack of sensitiveness in the nerve terminals of the glans penis and frenum. Various attempts were made to render those parts more sensitive, but without effect. Hypnotic suggestion has been considered but not employed. The possibility of there being some defect of the nerve arrangement in the cord has been thought of, but Robbins believes the anesthetic theory most reasonable.

6. **Puerperal Eclampsia.**—Wilson's treatment of eclampsia consists in the early administration of chloroform, giving it slowly until the patient is fully under its influence. The patient is kept anesthetized until the labor is terminated, so that she shall be partially under its influence for some time afterward. Wilson has found this treatment to be very successful, and has never seen any recurrence of the convulsions after labor, provided a short time only has elapsed after the first convulsion before the administration of chloroform is commenced.

9. **Prevention of Middle Ear Suppuration.**—Milligan directs attention to the following points: 1. The desirability or otherwise of removal of nasopharyngeal adenoids, enlarged tonsils and various forms of nasal obstruction during the acute phases of septic middle-ear disease. 2. The exact value of routine bacteriologic examination of secretion removed from the tympanic cavity in acute septic inflammation of the middle-ear cleft. 3. The employment or otherwise of inflation of the middle-ear cleft during the early stages of acute otitis media. 4. The value and limitations of palliative treatment as opposed to the early drainage of the mastoid antrum in cases of septic otitis media. The treatment which, in his opinion, conduces to the rapid cure of acute septic otitis media is the following: 1. Early and free incision of the swollen and bulging membrana tympani. 2. Maintenance of free drainage through the incised membrane. 3. Avoidance of inflation during the acute phases of inflammation of the mucosa lining the middle-ear cleft, the more especially if exudation has already taken place, and in the presence of a small perforation of the membrane. 4. Early removal of nasal and nasopharyngeal pathologic entities tending either to impair the physiologic function of the Eustachian tube or to favor reinfection of existing exudation within the middle-ear cleft. 5. Early provision of drainage from the postero-external end of the middle-ear cleft in those cases in which drainage through the membrana tympani has proved insufficient.

11. **Laryngeal Tuberculosis.**—Horne pleads for the conservation of the larynx by rational therapeutic and surgical treatment. Postmortem examinations have shown: 1. That when the larynx is infected with tubercle the disease is already established in the lung. Primary tuberculosis of the larynx is a negligible quantity. 2. That the disease in the larynx progresses *pari passu* with that in the lungs; when the disease in the larynx presents ulceration that in the lungs has advanced to cavitation, and, *vice versa*, when that in the lungs has become arrested, then that in the larynx heals. 3. That when the disease in the lung is confined to the pure miliary form the larynx is not infected. 4. That infection of the larynx takes place by the sputum from the lungs. Therefore, improvement in the larynx following treatment will coincide with the improvement in the lung. Remedies directed toward rendering the lungs aseptic Horne believes to be of considerable value in preventing infection of the larynx. He also believes that sanatorium treatment, both directly and indirectly, is beneficial to laryngeal disease. It improves the pulmonary condition and reduces the frequency of laryngeal complications; it affords rest of voice and promotes healing of laryngeal lesions. Local applications, both palliative and remedial, should form part of the sanatorium treatment. In the more advanced cases, surgical methods may be necessary; an enlarged epiglottis may have to be reduced or removed. Edema of the larynx may be overcome by linear scarifying. Infiltrated and thickened parts may be treated with the galvanocautery or by longitudinal incisions with a sharp knife. Indolent ulcers may be curetted and treated with lactic acid; but lactic acid applied to an unbroken surface is of no avail and only causes distress. The surgical treatment of the disease has its limitations, but within those limitations Horne has seen benefit afforded. He does not, however, favor extreme surgical measures; at their best they are only mechanical means of overcoming physical difficulties and are seldom called for.

18. Subtotal Hysterectomy for Fibroids.—This paper is mainly an analysis of a series of 60 cases of subtotal or supravaginal hysterectomy for fibroids in which the operations were performed by Doran; in every instance the patient had not reached the menopause and a sufficiently long after history was not obtainable. Each patient was traced for at least two years, and most of them were under observation for a much longer period of time. The main object of Doran's research was to determine: 1, How far the patients received lasting benefit from subtotal hysterectomy; 2, how far they are liable to certain discomforts, and 3, how far the preservation of more or less ovarian tissue may save them from those discomforts. There can be no doubt, says Doran, that so far as the removal of the tumor is concerned, the immediate results of this operation, after convalescence, are highly satisfactory, but uncomfortable or even distressing symptoms not rarely follow the operation; hence, the operator can not absolutely guarantee the patient against them. The surgeon must be careful how he urges an operation when the patient has a fibroid of small size which is not growing, which does not press on any important structure, and which is not the cause of hemorrhage. The presence of a small fibroid above the lower segment of the uterus does not justify any surgical procedure which may sterilize the patient, for pregnancy and labor often end normally in such cases. In many instances, however, the removal of the fibroid uterus is demanded, so that certain possible discomforts must be risked. Here the saving of the ovarian tissue has proved a direct benefit, and Doran's statistics confirm the value of that practice. A piece of the uterine mucosa should be saved whenever possible in order to anticipate and to prevent trouble from a premature menopause. In 28 cases of the series both ovaries were removed. In 3 cases the menopause was neither immediate nor complete; in 6 it was complete, with distinct but mild symptoms; in 10 it was complete, with severe symptoms. In 26 cases one ovary was saved. In 8 of these cases the catamenia was regular for a longer or a shorter period after operation; in 5 cases it was irregular, and in 13 cases the menopause was complete and immediate after operation. In 6 cases both ovaries were saved. In 3 cases the catamenia was regular after operation; in 2 cases it was soon suppressed, and in 1 case the menopause was complete and immediate after operation. In 5 of 16 young patients both ovaries were removed. The youngest patient was 30 years of age. She comes under the "severe menopause symptoms" class, but her flushings did not appear until eighteen months after the operation. Doran spared one or both ovaries in every patient under 30 years of age, with good results, and also saved ovarian tissue in several other relatively young women with benefit. He assumes that these patients would not have done so well had he sacrificed both ovaries. In 5 cases in which he was compelled to do so, bad symptoms appeared in 3. The majority of the 60 patients enjoyed good health when last heard from, two years or more after the operation. Doran concludes that the results obtained in these cases decidedly favor the conservative treatment of ovarian tissues, and that they tend to support the theory that it is necessary to spare some endometrium as well as some ovarian tissue.

19. X-Rays in Cancer.—Williams advises exposing cancer to the *x*-ray directly the diagnosis is made whether the case goes to operation or not. After operation, directly the scar is healed or even before that time, if it shows the slightest appearance of being sluggish, it should have immediate treatment whether in the scar or not; this requires constant observation by the medical attendant. A weekly examination is of the utmost importance to the patient. Even healthy wounds will heal the more readily under the stimulation of *x*-rays cautiously applied and in small doses, sufficient protection to the surrounding parts being all that is necessary. The *x*-rays used before operations, for even a few weeks, will tend to arrest further infection, and the glands, if enlarged with simple inflammation or only slightly affected, may disappear, with a certain amount of shrinkage of the original tumor.

21. After-Treatment of Cases of Suprapubic Cystotomy.—Colt says that there is great need of a suitable dressing for application to the patient during the period which elapses between the removal of the skin sutures and tube and the closing the urinary fistula. This time is at least one week: it is generally about three weeks and often longer still. The requirements are: 1, A dressing which shall be applied on the surface of the skin and which shall not enter the fistula at all—which shall not, therefore, tend to prevent it from closing or cause harm in any way; 2, a dressing which shall collect faithfully all the urine flowing by the fistula and allow it to drain away to a receptacle without wetting the patient's skin; 3, a dressing which shall in no way inconvenience the patient either by its bulk or by causing irritation of the skin or by its attachment to parts remote from the wound, as might very reasonably be necessary; 4, a dressing which shall only need occasional inspection and attention, just so much as may also be necessary for proper attention to the edges of the fistula, when, for instance, the granulations become exuberant; 5, a dressing which shall be transparent and so allow the wound to be seen easily, and, last of all, 6, a dressing which shall be easy of application, simple, unlikely to go wrong, and which shall also be cheap, aseptic, and easily cleaned and sterilized. Colt believes that he has met these requirements by the dressing which he has devised. This dressing consists of two parts, one being made of clear glass and the other of sheet rubber. The glass portion is a lightly blown hollow cylinder five-eighths of an inch in diameter and modified in that the top is partially closed and the bottom turned outwards as a flange. From the cylinder juts out a tube at right angles to its axis. The sheet rubber portion is a circular disc of the best, most flexible and elastic, untearable, black sheet rubber, three inches in diameter and one thirty-second of an inch thick. It has a central circular hole five-sixteenths of an inch in diameter and, therefore, can be easily sprung over the glass flange and arranged to lie in continuity with the concave portion of it. This is important for the proper application and stability of the apparatus. The joint so made is absolutely water tight. The two pieces when adjusted together and to a patient lying on his back are situated so that the cylinder is vertical and the rubber sheet horizontal. The total weight is 3 drams. A larger size is provided for use in the early stage, if necessary. The dimensions are a compromise of several, each of which has its own advantages and disadvantages. The rubber solution employed is made by dissolving pure rubber in naphtha. It is better put up in wide tins than in tubes. It is highly inflammable and the solvent quickly evaporates, both good reasons for keeping it securely sealed. The two parts of the dressing are sterilized separately, and the application is made as follows: The skin of the patient is shaved over an area of two inches all round the external opening of the fistula. It is then cleared of grease with a swab soaked in ether. The tin of rubber solution is opened and the surgeon sterilizes his hands. He dries them and both parts of the dressing thoroughly with a sterilized towel or with wool, fits the two parts of the dressing together correctly, and adapts the long rubber drainage tube to the short connecting arm. A small swab of absorbent wool is kept on the orifice of the fistula so that the skin around may be dried and kept perfectly dry until the dressing is applied. This swab should be renewed quickly if it becomes soaked, and it should be small enough to allow the rubber solution to be applied close up to the opening. The surgeon dips his finger in the rubber solution and thoroughly coats the patient's skin with a thin even layer right up to the opening and round it for a distance of two inches, rubbing the solution well in. Care should be taken not to continue the rubbing if the solution begins to peel off. The under surface of the rubber disc is then covered all over with solution, but not within one-eighth of an inch of the glass flange or the spring of the rubber is weakened and thereby also the security of the water-tight joint. The rubber flange bends back of its own accord into three most convenient folds like a three-cornered hat. Then the surgeon waits until the two surfaces are nearly dry, as tested with the finger. That on the skin takes longer and it is immaterial how dry the surface of the rubber is. To refuse to wait is to court failure. As soon as the correct moment arrives the central swab is removed for good and the glass flange is placed around the opening of the fistula, and before any urine can escape the rubber disc is pressed evenly down all round. In making the adjustment it should be remembered that the drainage tube should either point toward the pubes with the rubber tube arranged for the side on which he lies, or it should be turned one-eighth of a circle or so to that side. There should be no attempt at rectification when once the application has been made. The excess of solution is rubbed off the skin round the disc with the finger. It comes off readily enough in little pellets while it is still damp with the solvent. The rubber tube is now bent round in a curve and fixed to the skin by a broad band midway between the anterior superior iliac spine and the orifice of the fistula, and in such a manner that the glass is kept in correct position partly by the elasticity of the drainage tube itself. The top of the glass is lightly covered with a piece of gauze or wool. or the hole is lightly filled, to prevent sepsis. The drainage tube is threaded through the cradle if one is being used and allowed to hang into the pail. It should be as short as can be contrived. The patient should be instructed to raise up any bedclothes he may have on the dressing when the nurse has to change them or attend to him, otherwise they will catch in it and it will be swept off. He should also be told not to strain to pass urine. When carefully applied the dressing is usually efficient for at least four days. If urine leaks under the rubber the dressing should be removed by peeling it off from the edge, another rubber substituted, and the whole reapplied. It is generally impossible to readjust it without reapplying it as a whole, though often a strip of plaster applied over the rubber will prevent leakage for one day longer.

26. **Hygiene of Mother Before Parturition.**—Ballantyne discusses the influence on the fetus of various conditions affecting the mother, dividing the antenatal life of the child into the germinal, the embryonic and the fetal. He advises examining the placenta chemically and histologically in every case of labor, and comparing the results obtained with clinical data in order to determine, if possible, the microscopic appearances characteristic of a placenta capable of transmitting power and those of one in which the transference of materials, nutritive, medicinal or poisonous, was difficult or impossible. It should be determined how pathologic changes in the deciduæ, amnion and chorion are related to the previous health of the mother and the present condition of the embryo. Again, a strict comparison ought to be instituted between the health of the mother and the state of her offspring in succeeding pregnancies. The maternal influence on the fetus is a complex matter, and until such time as definite information about the feto-maternal interchanges is forthcoming, the treatment of these conditions must be empirical. The hygiene of the pregnant woman is discussed in detail.

27. **Mother's Milk.**—Jones divides causes of non-lactation into four groups: 1, Women who can but refuse to nurse their infants; 2, women who have serious difficulty in nursing because of some anatomic defect; 3, women who have an abundant supply of milk during the first three or four weeks and then run dry; 4, women the chemical composition of whose milk does not agree with the digestive organs of the child. In some instances the milk is of low nutritive quality and deficient in fats; the infant's digestive organs may be at fault; the mother may be extremely nervous and excitable, or she may be ingesting something which produces a disturbance of the child's digestive system. If the infant can not be nursed by its own mother, Jones advises procuring the services of a wet nurse. Failing human milk, the physician must choose between modified milk, either of the cow or of some other animal, and artificial foods.

28. **Artificial Feeding of Infants.**—Nothing new is presented in this article. Cautley emphasizes the importance of weighing the child regularly for the purpose of regulating the diet so that there is a constant gain in weight. The time of feeding, the preparation of the food and the kind of food to be used are also considered. Cautley says that by the intelligent use of properly prepared milk and the plain cereal decoctions, it is quite easy to bring up infants successfully without having recourse to laboratory mixtures or to any of the death-dealing condensed milks and proprietary foods, although there are cases of disease in which they are valuable, when used with discrimination by those who thoroughly understand the art of infant feeding.

29. **Use and Abuse of Condensed Milk and Patent Foods.**—Still calls attention to the fact that the suitability of a particular food for prolonged use is not proved by the fact that it is taken well and produces no immediate ill-effects. The evil results of unsuitable food may not appear until the food has been continued several weeks or months. An objection to all prepared foods is their deficiency in fats. As for condensed milk and the other substitutes for fresh cow's milk, Still says that no manner of simple dilution of water can make the resulting mixture a suitable food for the prolonged use of infants; nevertheless, these foods may be of value for short periods under special conditions. The starch-containing patent foods are useful sometimes for infants over nine months of age, when starch is gradually to be introduced into the diet, but they must be given cautiously and with due regard to the digestive apparatus of the infant. The more the medical man knows of the many simple methods of adapting fresh milk to the needs of the infant, the less use he will find for condensed milk or patent foods.

30. **Municipal Feeding of Infants.**—McCleary outlines the methods pursued by various municipalities in England, especially in the borough of Battersea. These methods are based on the consultations in vogue in France.

31. **Consultations for Infants.**—Robinson describes these institutions which have done so much to reduce the infant mortality from gastrointestinal diseases in France. There are seven consultations for infants in Paris, and two in the immediate suburbs, exclusive of those connected with maternities. Each consultation must contain an apparatus for washing, cleaning and drying the empty bottles returned daily by the mothers. The milk is sterilized by the female caretaker, assisted by one helper; it is only delivered to infants according to the physician's prescription. The hygiene and feeding of the infant out-patients is under the supervision of the physician in charge of the consultation. Thanks to these institutions, more mothers feed their infants at the breast, the general infantile mortality is lowered and infantile diarrhea disappears. Stronger healthy children who resist every ailment better are seen because their digestive tube has not been deteriorated.

32. **Infantile Mortality.**—Newsholme's paper is a statistical study from the public health standpoint of facts derived from

the annual reports of the registrar general of births, deaths and marriages in England and Wales.

33. **Infantile Diarrhea.**—The treatment of the early stage of infantile diarrhea advised by Sutherland consists in the thorough cleansing of the intestinal tract as quickly as possible. He prefers castor oil administered in small repeated doses. It is given as follows:

℞.	Olei ricini	m. x		6
	Tinct. rhei			
	Glycerini, āā	m. v		3
	Tragacanthæ	gr. 1/2		03
	Aq. menthæ piperitæ ad	℥i	4	

This may be given in teaspoonful doses every four hours for the first thirty-six hours, and then less frequently. It is usually well tolerated by infants, but if there is much gastric disturbance and vomiting, it may be necessary to wash out the stomach first. Instead of the castor oil one may use small doses of mercury. Gray powder, in one-quarter grain doses, or calomel in one-sixth grain doses, may be given every two hours, until six doses have been taken. When the acute symptoms are subsiding, and the motions are becoming less frequent, this sedative mixture may be given:

℞.	Sodii sulphocarbolatis			
	Bismuthi subnitratis, āā	gr. ii		1
	Tragacanthæ	gr. 1/2		03
	Glycerini	m. x		6
	Aq. dest. ad	℥i	4	

One teaspoonful of this mixture is given every six hours. Associated symptoms are treated as they arise.

34. **Convulsions in Early Infancy.**—Thomson gives a general *review of this subject.*

35. **Vaccination.**—Greenwood says that in considering the conditions that contraindicate vaccination and render postponement advisable, the presence of smallpox locally, in a sporadic or epidemic form, is of the utmost importance. Where postponement might be desirable and even imperative in the absence of smallpox, when this disease is epidemic or has broken out in the house where the child resides, vaccination ought nearly always to be performed. When smallpox is not present and there is no immediate fear of the infection, the child should be vaccinated when its health is at its best. If the child has been exposed recently to an infectious disease, vaccination should be postponed until a reasonable time has elapsed from the convalescence of the last patient. When a child suffers from any form of wasting disease it is better not to urge the operation unduly. Care should be taken that the condition of the child's skin is healthy. With regard to postponement in general, it must not be forgotten that it is an evil; anything that can be done to avoid the necessity of postponement is, therefore, important. One method is to offer vaccination as soon after the first month as possible. The operation must be carefully performed under aseptic precautions.

36. **Infantile Scurvy.**—Colman details the clinical history of this affection, laying particular stress on the morbid anatomy and frequency of occurrence of the bone lesions.

44 Etiology and Treatment of Hernia in Adults. R. H. Russell.
45 *Simplified Operation for Hernia in Children. E. K. *Herring.*

45. **Simplified Operation for Hernia in Children.**—Herring describes his method, a simple and rapid one, as follows: "Cut down on and *into* the sac in the usual position over the rings, and having dealt with the contents, pull the sac down, i. e., out *from* the abdomen, sufficiently to insure the subsequent retraction. Extend the incision in the sac right up to the ring margin, and turn this upper portion of the sac inside out through the incision, exposing the peritoneal surface. Then, with a knife or pair of sharpened scissors, cut the peritoneum (only) transversely right across. The proximal cut edge will retract within the abdomen, so catch it here and there as you cut with catch forceps. Thus the sac is severed from side to side, and the proximal opening is held by forceps. Arrange these forceps to draw the edge into a line, and whip it together by a catgut suture. Take off the forceps and the sutured opening will retract within the abdomen. Close the wound with a subcuticular or other stitch and seal it." The operation is done in a few minutes, instead of the ordinary three-quarters of an hour. Nothing further is absolutely necessary. When there is a large lax abdominal ring, or when the little patient has a cough, it may be advisable to put one or two stitches through the pillars as a temporary support. The contents of the inguinal canal are practically not disturbed. The sac is left in the canal to shrivel up; the cord has not been touched nor pinched; the testicle has not been dragged out and exposed; no vessels have been cut, so no ligatures are left behind, and the chances of sepsis are very slight.

46 (XXV, No. 44.) *De l'influence de l'alcoolisme sur la glande thyroide. F. De Quervain.
47 Report of Fifteenth Italian Congress of Internal Medicine, Genoa, October 24-29.

46. **Influence of Alcohol on Thyroid Gland.**—De Quervain has previously published a study of acute, non-suppurative thyroiditis and of the participation of the thyroid gland in acute infections and intoxications. In this article he studies the influence of alcoholic intoxication. The thyroid gland reacts in about the same way to microbian intoxications as it does to chemical poisons. The colloid substance becomes more or less granulous and filled with vacuoles, while it diminishes in amount. It ceases to stain with eosin and takes hematoxylin, while there is intense epithelial desquamation and hyperemia. In examining the cadavers of pneumonia subjects he noticed that those with a history of alcohol addiction showed these changes to a marked degree, while they were absent in the non-alcoholic cases. The thyroid must be added to the list of glandular organs susceptible to injury from alcohol. It might be interesting to study the indications of lacking or defective thyroid functioning in cases of chronic alcoholism. The knowledge of the changes induced in the thyroid gland by alcohol throws light on the development of spontaneous myxedema or "hypothyroidism" in the children of alcoholics. Such modifications as those described, if they occur in the thyroid of the fetus, might well explain its defective functioning later.

48. **Operative Treatment of Complete Occlusion of the Intestine.**—Simon reviews the cases treated at Czerny's clinic between 1890 and 1903, separating them into eight classes according to the cause, etc., of the occlusion. He proclaims as the lessons learned from this extensive experience that all cases of internal occlusion in which strangulation is probable, and also of volvulus and invagination, should be treated operatively, but that in case of gangrene, the intestine should merely be drawn out and opened instead of attempting more

radical measures. In complete occlusion, especially with preceding chronic obstipation, internal medication should be given a trial, but the response must be obtained in the first or, at the most, in the second twenty-four hours, not to allow the favorable moment for intervention to slip past. Every operation for complete intestinal occlusion should be preceded by lavage of the stomach. In case of much meteorism, the intestine must be emptied at the time of the operation. In case of existing peritonitis it is always wise, Simon states, to leave a fistula into the intestine, notwithstanding the restoration of the permeability of the bowels.

53. **Permanent Cures of Mammary Cancer.**—Schröder's article is devoted to the experiences with mammary cancer at Müller's clinic at Rostock, 1875-1901. The total number of patients treated by a complete operation was 347. Out of this number 45 are still alive and well, one after twenty-seven and a half years, and 14 after from ten to fifteen years. In 15 of the 182 patients who succumbed to metastases there was no local recurrence of the neoplasm. In a majority of cases in which a second operation was required the recurrence was in the cicatricial tissue. In 5 cases the recurrence appeared between the fourth and fifth year after the operation; in 4 between the fifth and sixth year, and in 6 between the sixth and eighth; in one after eleven and in another after thirteen years. The fact that in 51 out of 83 cases of recurrence the latter occurred in cicatricial tissue, suggests that the operation spared too much skin. Cancer germs must have been left in the skin, and this should have been excised more freely. Some of the patients had showed the lump to their physician and he had advised waiting "to see if it got any larger." There will always be a small proportion of cases in which the growth is still apparently in its incipiency, but yet the patients succumb to speedy metastasis in lungs or pleura. The lymph vessels in the mammary gland communicate with the mediastinal glands, which explains this group of cases. Fortunately, this communication is less extensive than that with the axillary glands.

58. **Trachea in Roentgen Picture.**—Füster proclaims that the trachea can be inspected with great precision in the Roentgen picture even in case of large goiters. It enables the part of the goiter encroaching on the trachea to be determined, and gives a number of other hints valuable for surgical intervention.

59. **Spinal Analgesia.**—Pfeiffer's communication issues from von Hacker's clinic at Graz, and describes 235 cases of operations performed under spinal analgesia. No by-effects were observed in 75 per cent. of the cases and in the others, with a single exception, they were slight and brief. In only 10 cases was there absolutely no analgesia after the injection. General anesthesia after a preliminary spinal analgesia requires much less of the anesthetic and seems much less serious than under. other conditions.

67. **Subphrenic Abscess.**—Perutz reviews 158 articles in his text and adds several more to the list in correcting the proof. He classifies the cases as they originate: In the stomach, 67 cases; duodenum, 3; appendix, 55; liver and biliary passages, 17; echinococcus cyst, 5; intestine, 7; pancreas, 4; spleen, 4; perinephritic structures, 7; ribs, 1; thorax, 8; female genitals, 6; of traumatic origin, 8; metastatic, 5, and unknown and various causes, 11—a total of 208 cases, with 6 added in the proof, bringing the total number to 214. Ulcerative processes in the stomach and appendicitis are the principal causes of subphrenic abscess formation. The symptoms may be acute or more insidiously chronic. The patients may grow thin and appear very ill without any local symptoms to attract attention to the site of the lesion. As a rule, however, some of the organs in the vicinity are pushed up when fluid accumulates on the lower aspect of the diaphragm. The affected side protrudes more than the other, and there may be fever and extreme difficulty in breathing. The affected side may lag in making the respiratory excursions. The area of dullness over the tumor corresponds to the convex outline of the diaphragm, and the limits of the lungs above can be differentiated in some cases, but not in all, as the excursions of the pleura are generally hindered by extension of the inflammation or by exudation. If the abscess contains gas, then the picture is that described by von Leyden as subphrenic pyopneumothorax. The remarkably extensive lymphatic communication between the pleura and the subdiaphragmatic space renders the participation of the pleura in the inflammation almost inevitable. It is favored by the movements of the diaphragm. The pleural exudate is generally less virulent than the contents of the abscess. Grüneisen found the pleura involved in 40 out of 60 cases of subphrenic abscess. In 3 instances the subphrenic abscess was the result of a bullet wound. In another it developed after a strain from lifting a weight, and in some others after contusions. In these cases an extravasation had probably become infected. The abscess was of typhoid origin in a few individuals and it followed furunculosis in others. The possibility of a subphrenic abscess should be borne in mind when confronted with furuncles, especially when on the face. In 2 cases the abscess followed tuberculous peritonitis, and in a third the pus contained pneumococci. In a few other puzzling cases pneumonia or pleuritis was diagnosed at first, but the atypical course, the high fever, and the general ill feeling, supplemented by the puncture findings, cleared up the diagnosis. In one case in this group the patient succumbed to thrombophlebitis of the splenic vein. The others recovered, one man requiring counteropenings and several months in bed before he was finally cured.

68. **Clinical Value of Cryoscopy.**—Ziesche concludes his long analysis of what has been published on the study of the freezing point of blood and urine with the remark that the extravagant claims made for this new diagnostic measure at first have not been substantiated, but that it is valuable in supplementing other diagnostic measures, and states that it will well repay further study. Defective technic has been responsible for some of the conflicting reports which have been published. He reviews the works on osmosis and on the determination of the freezing point which preceded Koranyi's application of cryoscopy to the clinic. Very little has been done in pediatrics with cryoscopy. It seems to have been demonstrated that in liver affections the freezing point of the blood is higher, while in diabetes it is lower. This may be due to irritation of the kidney or to weakness of the heart, or to accumulation of acetone in the blood. Koranyi regards the acetone as similarly responsible in case of inanition. In diabetes insipidus the freezing point of the urine is very high; Strauss has observed a patient with an output of 6 liters and a freezing point of 0.11 C. The smallest figure yet recorded in man for the freezing point of the blood was found by Dienst in a case of eclampsia, namely, 0.40 C.

69. **Meckel's Diverticulum.**—Dreifuss has sifted 398 articles and discusses the subject from every point of view as presented in the literature. He summarizes his conclusions in the statements that an open diverticulum should receive the most radical treatment at the earliest possible moment. In secondary prolapse of the intestines Barth's technic is preferable, as it provides for all eventualities. Enterostomata should be extirpated, and the diverticulum in a hernial sac should be removed as completely as possible, as under all circumstances. Inflammations in the diverticulum and ileus—whatever their origin—must be regarded as surgical affections and preferably treated according to Hilgenreiner's technic. An operation was performed in 111 of 192 cases of occlusion of the intestines by a Meckel diverticulum. In 32 cases the patients were saved, but in the other 79 the fatal termination could not be arrested. Hilgenreiner thinks that these figures

will grow better when it is generally accepted that every case of ileus should be regarded from the first as a surgical affection—not that the surgeon has to operate in every case, but that expectant treatment should be with the knife in hand.

70. **Hyperemesis Gravidarum.**—Pollak recapitulates the views and methods of various authors as set forth in 242 articles published between 1895 and 1904. The prognosis is given as more favorable in these later works. Many writers preach against the use of medicines, claiming that when this method of treatment is successful it is merely from suggestion. Olshausen gives 4 gm. of potassium bromid in rectal enemata during the day, keeping the patient in bed. Kehrer gives 1 gm. of sodium bromid three times a day and 15 drops of nux vomica once, with a solution of cocain. Antonschwitsch gives salts in large doses, ascribing the trouble to a deficiency in salts. Neustube gives 10 drops of a 50 per cent. solution of cocain, repeating the dose in an hour if the desired result is not attained, and once again, with half the dose, three times the next day. He inserts a tampon with a 2 per cent. cocain salve in the vagina at the same time. Pozzi has also reported success from subcutaneous injection of cocain, Bauer with cocain internally and morphin subcutaneously. Opium is recommended only by Priest and Tuszkai in the literature of the last ten years. The latter gives it in large doses. Oelschlager reports that he has never had a failure in fifty years' experience with sodium bicarbonate combined with tincture of strychnin. Dirmoser gives 0.05 gm. calomel every hour until the bowels move and then morphin. Dow prescribes a teaspoonful of a 1 per cent. solution of carbolic acid by the mouth after failure of other measures. Some writers reject medication, as its almost certain failure destroys the patient's confidence in her physician, and time is wasted. Geoffroy noted that the vomiting ceased after prolonged palpation and consequently proposes massage as a remedy. He ascribes the trouble to reflex contraction of the pylorus, duodenum and junction of ileum and colon, and consequently advises massaging these parts. His suggestion does not seem to have been adopted by others. Several writers have reported cessation of the vomiting after correction of some displacement of the genitals. A number of authors recommend treatment as for hysteria, especially with authoritative suggestion. Frank wonders that more use is not made of hypnosis by gynecologists. A number of instances have been recorded in which hyperemesis gravidarum was noted in the previous history of patients with polyneuritis. Eulenberg has observed 3 such cases.

71. **Acute Dilatation of the Stomach.**—Neck has collected 44 cases with postmortem findings published in the literature. The stomach generally reached to the pubic bone and in some instances the floor of the pelvis. The signs of the distension of the organ came on suddenly usually, without any previous history of gastric disturbances. In 28 of the cases the dilatation occurred after an operation under chloroform. In 17 the operation had been on the abdomen, with a possibility that the stomach might have been pulled or injured in some way, directly or indirectly, but in the other cases the operation had been resection of the knee or elbow, amputation at the hip joint, or operations on the foot or knee. It is more than probable that the stomach was injuriously affected by the chloroform, entailing paralysis and stretching of the walls. In a case recently observed a man took chloroform several times without harm, but sudden dilatation of the stomach followed two hours after a single dose of 0.1 gm. of veronal. Neck cites this instance to illustrate the idiosyncrasy of the stomach against some drug which is probably the cause of the sudden acute dilatation of the stomach in certain cases. In the other cases inordinate or inappropriate eating or drinking had preceded the dilatation—four bottles of champagne in one case, two bottles of lemonade in another. Acute dilatation has also been observed after contusions of the abdomen or other trauma. Vomiting generally occurs, but not invariably, and it may cease abruptly. There may be considerable pain at various points. Certain symptoms suggest the action of toxins. In all but 2 of the cases the temperature remained normal throughout. Out of the total of 64 cases which he has collected only 17 terminated in recovery. Differentiation from ileus and peritonitis is very difficult, as a rule. In treatment, the use of the stomach pump three times a day best answers the indications; it must be continued until the stomach has returned to normal size and the signs of functional disturbance have subsided. It is a good plan, Neck says, to evacuate the stomach with the patient's pelvis raised, as this facilitates the emptying of the organ. Interference with the bowel functions by the distended stomach can be counteracted by having the patient lie face downward or change to the knee-elbow position for fifteen minutes every two hours, Kelling's patient obtained relief by lying on the left side with the legs drawn up. Borchardt had an unfavorable experience with the prone position, and thinks that it is liable to interfere still further with the motions of the diaphragm, and possibly to arrest the heart action. If the prone position is ordered, the stomach must be systematically evacuated from time to time. Surgical intervention is the last resort, but a gastroenterostomy might be tried. It has been done in a few instances, but too late to benefit the patient. The cause of the acute dilatation may be manifold, but experience has shown that in addition to and in consequence of the dilatation there may be compression and kinking of the duodenum which in turn increase the dilatation. The compression of the duodenum generally occurs just below the superior mesenteric artery. Sometimes the duodenum is kinked by traction or torsion from the enlarged stomach. The dilatation of the stomach is the primary lesion.

74. **Pathologic Conditions of the Basilar Artery.**—Saathof's attention was called to the mechanism of aneurism of the basilar artery by the case of a man carrying a hod of bricks on a scaffold, who stepped on the loose end of a plank and fell through to his thigh. This kind of trauma caused an impact of the skull on the neck and resulted in the rupture of the sound basilar artery. In 3 other cases thrombosis in the basilar artery was evidently a syphilitic process. Saathof is convinced that the peculiar location of the basilar artery exposes it to great injury from an accident such as the one just described, the impact of the weight above forcing the artery against the rough bone below. Examination of 100 skulls showed that the bed of the artery was smooth in only 43, while all the others exhibited more or less numerous jagged projections. Injury of this kind might pass unperceived, but would leave a place of lesser resistance on which a syphilitic process would locate by preference. He has found in the literature reports of 10 cases in which the basilar artery was the sole seat of syphilitic gummatous arteritis. In another group, which he also illustrates with examples, the syphilitic process had involved the neighboring arteries, while a third group includes those in which the adjacent membranes as well as the arteries were involved. This [illegible] chain of trauma, thrombosis, syphilis and aneurism [illegible] also the hitherto puzzling fact that the region of the [illegible] seems to be a favorite site for syphilitic lesions.

liarly sheltered position of this part always rendered its predilection for syphilitic lesions inexplicable. But if we ascribe causal importance *to trauma affecting the basilar artery*, then the propagation of the process to the region of the chiasma is not improbable. In a large number of the cases on record *trauma is expressly stated.*

75. Study of Blood Pressure and Pulse Curve.—Fellner's work issues from Nothnagel's clinic. The conclusions state that the measurement of the blood pressure, according to the Masing-Sahli-Strasburger technic, denotes great progress in this line, especially in the determination of the diastolic with the systolic pressure, and also the extent of the pulsatory increase in pressure (pulse pressure). This enables us to determine the condition of the circulation at any time, the degree of compensation, the diagnosis of various disturbances in the circulation and allows exact control of many therapeutic measures. It gives extremely characteristic and important diagnostic findings in certain affections, especially in case of aortic stenosis or insufficiency, and of nephritis. The pulse pressure is, further, the only means of determining accurately the degree in which the pulse is gaining or losing. This can not be determined by the ordinary sphygmogram, but can be learned with precision from Sahli's "absolute sphygmogram." The viscosity of the blood has considerable influence on the origin and shape of the pulse curve. The Riva-Rocci sphygmomanometer is more reliable than any other, Gaertner's tonometer giving only approximate findings. By the Strasburger technic, the Riva-Rocci cuff is slipped on the forearm as usual and connected with the manometer. The maximal pressure is estimated by the height of the mercury column when the pulse vanishes peripherally from the point of compression. The diastolic (minimal) pressure is estimated at the moment when the previous maximal radial pulse commences to grow smaller with increasing compression. Sahli's technic consists in applying Jaquet's sphygmograph, instead of the fingers, to the radial artery, and then compressing the brachial with the cuff. As the sphygmogram record grows smaller, this corresponds to the diastolic pressure. When the systolic pressure is reached in the cuff, the index marks a horizontal line *without elevations. The findings by both these technics are practically identical.* The Strasburger shows the minimal pressure = heart diastolic pressure; maximal pressure = heart-systolic pressure. The pulse pressure is the difference between the maximal and the minimal pressure. The blood pressure quotient = the quotient obtained by dividing the pulse pressure by the maximal pressure. Sahli's work on methods of clinical investigation was reviewed on page 1673. Some of his communications have been summarized in The Journal, for example on page 1819 of volume xliv, and page 2002 of volume xliii. Fellner does not regard the blood pressure quotient as a reliable index of conditions, as various factors combine to influence it; but Sahli's absolute sphygmogram, he thinks, can be relied on. The ordinary sphygmogram represents a curve with an unknown base. We have no means of knowing with the ordinary sphygmogram the base line representing the distance from zero. A pulse with a minimum of 60 mm. and a maximum of 90 mm. would show exactly the same findings as another with a minimum of 160 mm. and a maximum of 190 mm. Sahli draws on "millimeter paper" the time of one pulse phase (0.2", according to Jaquet's sphygmograph 10 mm.). The height of the minimal pressure is then marked on the zero line (the minimal pressure is determined by the Riva-Rocci, for instance 1 mm. mercury ≙ 1 mm. on the vertical line), corresponding to the height of the pulse curve, that is, the maximal pressure is marked at the point to correspond to the time distance. In an absolute sphygmogram thus drawn, *the height corresponds in fact to the pulse pressure.* The future of the sphygmogram is for the exact study of rhythm, frequency and regularity of the pulse and its disturbances. In solving other questions, however, the study of the venous pulse and of the cardiogram should supplement sphygmography and sphygmomanometry, with also plethysmographic findings and analysis of the blood. The entire arsenal of hemodynamics may be called on before the problem is solved in certain cases. In conclusion he cites von Frey *to the effect that if the study of the pulse is to be more than a mere pastime, it should be applied to several parts at once, investigating the pulse in various regions, if possible, with different apparatus and simultaneously.*

76. Embolism of Pulmonary Artery.—Hart describes 2 cases in which the main trunk of the pulmonary artery had evidently been completely obstructed by an embolus. The far advanced organization testified to the long existence of the lesion, but weeks elapsed after the embolism before the patients succumbed.

79. Infarcts in Spleen and Kidneys.—Riebold's article is based on 2 cases. The patients were young women, and the first sign of trouble was a sudden excruciating pain in the region of the organ affected, strictly localized, not radiating, persisting for some time unmodified without essential remissions, but gradually subsiding in the course of a few days. An infarct in the spleen or kidney *may occur with severe symptoms suggesting ileus or peritonitis*, probably of reflex origin (collapse, vomiting, retention of feces and urine). These symptoms may be accompanied by slight temperature and possibly also by moderate leucocytosis. Head's zones of hyperalgesia on the skin are sometimes noted, and their location on the right or left side may sometimes have diagnostic importance to determine whether the left kidney or the spleen is affected. Enlargement of the spleen and friction in the splenic region point to this organ. In case of infarct in the kidney, oliguria is sometimes observed or anuria, with hematuria and albuminuria, and yet it is possible for the urine to be entirely normal even in case of very extensive and bilateral kidney infarcts. *In some cases the infarcts occur with no symptoms to suggest their presence.* In one of the cases described an embolus was found in the basilar artery, and was the cause of the acute bulbar paralysis that had been observed, but a small isolated hemorrhage in the thalamus optici had failed to cause facial paralysis.

80. Pathology of the Blood Pressure.—Külbs describes a dozen cases in which he observed a temporary increase in the blood pressure in persons addicted to tobacco or alcohol. It was accompanied by subjective sensations, with a very tense, regular pulse and acute dilatation of the heart. The patients complained of a pain or sense of oppression, as if a great weight were lying on their chest. Conditions were restored approximately to normal by rest in bed, baths and restriction of intake of fluids.

82. Is Homogeneous Blood Retained on Transfusion?—Schultz relates experiments which he thinks demonstrate that carefuly defibrinated rabbit blood transfused into other rabbits is preserved for the receiving organism for the most part.

85. Behavior of Electrolytes in Urine During Changes in Circulation of Blood Through the Kidneys.—Loeb's conclusions from the extensive clinical research reported are *to the effect that in healthy individuals the elimination of urine increases when they change from the reclining to the upright position, and the relative elimination of salt increases also.* In individuals with disturbances in the circulation the changes are just the reverse. Those with orthostatic albuminuria show *modifications in the urine which indicate that the circulation through the kidneys is not so good when standing. Nitroglycerin has an unfavorable action on the circulation through the kidneys in case of nephritis. In the changes indicated in the urine by upright position or by nitroglycerin, salt behaves differently from the other solid constituents of the urine, as the changes in concentration occur in an opposite sense to those of the other solid constituents.*

86. Laparatomy in Tuberculous *Peritonitis.*—*Göschel* reports that one of the 3 patients whom he reported as cured (see The Journal, page 1035), later returned with progressing lesions. After six years of apparent cure the tuberculous peritonitis resumed a progressive course.

93. **Contagiousness of Erysipelas.**—Franke's research has demonstrated, he thinks, that the streptococcus enters through some solution of continuity in the skin or mucosa, possibly so minute as to be imperceptible. The coccus penetrates into the lymphatics beneath and sets up erysipelas or an abscess, according to the depth of its penetration or its virulence. It never comes to the surface in the vesicles or cast off epidermis, any more than in case of a phlegmon in a tendon sheath. The erysipelas patient is no more dangerous, he states, as a source of contagion than a patient with a phlegmon of this kind, so long as he does not scratch the patches. If they are scratched the lurking places of the streptococcus are liable to be disturbed and the exuding fluid may contain virulent streptococci. An erysipelas patient should have the patch covered with a protecting dressing the same as any abscess or phlegmon, and when this can be done effectually the patient, Frankel says, is no more dangerous to those around him than any patient with an infectious process. If the patch is on the face or where it can not be effectually protected, the patient had better be isolated until the symptoms of inflammation have subsided. When these are gone isolation can be suspended, as there is no danger of contagion from the scaling.

94. **Action of Roentgen Rays in Leukemia.**—Heineke expatiates on the remarkable harmony between clinical experience and the results of experimental research in respect to the action of the Roentgen rays on the cells of the blood-forming organs. After exposure of guinea-pigs for several hours to the rays, the white cells of the bone marrow, with but few exceptions, are destroyed. This destruction of the white marrow cells commences at nearly the third hour, reaches its height at about the eleventh hour, and the process is terminated by the end of five or six days. The lymphocytes succumb first and the ungranulated myelocytes, then the eosinophiles and the mast and giant cells, while the neutrophile polymorphous polynuclear cells remain intact longest. The injured bone marrow is capable of regeneration, which commences at about the second week and is complete by the third or fourth. During regeneration the ungranulated and the giant cells appear first, while the eosinophiles and the mast cells are the slowest to appear. These findings were obtained in 150 guinea-pigs after a single exposure of several hours' duration. They harmonize perfectly with what has been observed in the clinic, but the lymphoid tissue in man does not react so promptly and decidedly as in animals. The glandular tumors of pseudo-leukemia generally respond to Roentgen exposures with prompt retrogression, though some cases prove refractory. The soft, rapidly growing glandular tumors, abounding in lymphocytes, respond best to the exposures, as he illustrates by the report of a case personally observed. The possible rapid regeneration of the tumors when the exposures are suspended is one of the facts which testify that the rays do not reach the causal agent. Experiences with sarcomata indicate that those whose cells approximate most closely the lymphoid tissue are most susceptible to the action of the rays. In man the rays seemed to exert a favorable action on the red cells and the hemoglobin, but no confirmatory findings of this have yet been obtained in animals.

99. **Decapsulation of Kidney for Scarlatinal Anuria.**—The patient was a boy of 6 with acute, threatening anuria for several days, but no signs of nephritis, on recovering from scarlet fever. The kidney was exposed under chloroform anesthesia and the capsule slit. The kidney was a dark brownish, bluish red in color, soft but not distended, and when the puncture needle was introduced for 1 cm. half a dozen times very little blood escaped. The wound was sutured over a gauze drain and the child rapidly recuperated and soon regained his usual health.

101. **Relative Valvular Defects in Anemia.**—A positive centrifugal pulse is sometimes noted in the jugular vein in case of anemia, von Leube announces. It may be slight or pronounced, and is evidently the consequence of the functional muscular insufficiency of the tricuspid valve, the result of anemia. The origin is the same as for the relative mitral insufficiency in chlorosis. The symptoms in each case subside as the patients progress toward recovery. The relative tricuspid insufficiency in anemic individuals appears at the same time as the relative mitral insufficiency, in which it differs from the tardily appearing tricuspid insufficiency in the course of an endocarditic mitral defect. This early coincidence with mitral insufficiency and its persistence without severe disturbances in the circulation, are grounds for assuming the relative character of the mitral defect. A positive centrifugal venous pulse is also observed at times in anemic subjects without signs of tricuspid insufficiency. In some of these cases at least, this must be referred to a latent tricuspid insufficiency which may eventually become manifest.

103. **Polycythemia and Enlarged Spleen.**—Reckzeh states that reports of 29 cases of this affection have been published, and he adds to the list 5 personally observed. It seems to be an established fact that the symptom-complex of polycythemia with enlarged spleen and cyanosis can be observed in connection with primary tuberculosis of the spleen, but it is equally well established that the syndrome can occur without a tuberculous affection of the spleen. In one of Reckzeh's cases a young man presented a slowly growing malignant tumor of the thymus and lung which caused gradual compression of the superior vena cava. The result was cyanosis, polycythemia and enlargement of the spleen. Experiments on animals confirmed the lesson learned from this case, namely, that compression, causing stagnation of the blood, is alone sufficient to induce the development of the syndrome. Stagnation of the blood is probably, therefore, the cause of all the cases. This stagnation may be the result of diminished tonicity of the veins. The prognosis is generally bad, the cases progressing slowly to a fatal termination although showing marked and prolonged remission at times. Iodin, quinin and arsenic failed to produce any permanent benefit in his experience. Ehrlich recommends quinin and regulation of the diet to avoid iron. In one case Türk gave up to 30 drops of Fowler's solution daily for months and beheld the symptoms subside under this treatment. Symptomatic improvement has been obtained by withdrawal of blood, but it proved merely transient. Splenectomy has been proposed, especially for the cases with tuberculosis of the spleen. Reckzeh comments that it is impossible to diag-

nose positively a tuberculous affection of the spleen even with an exploratory incision. The hemorrhagic diathesis displayed by these patients should also suggest caution. In 3 cases on record splenectomy had an unfavorable effect, but, on the other hand, 8 cases are on record of isolated tuberculosis of the spleen in which a cure followed extirpation of the organ. Roentgen treatment has been tried and Vaquez and Laubry report improvement in the general condition in one case after three exposures with seven-day intervals; the composition of the blood remained uninfluenced.

104. **Leucopenic Splenomegaly.**—D'Amato concludes from his examination of 2 cases of Banti's disease, 2 of chronic malaria and one of syphilis affecting predominantly the liver and spleen, that the cause of splenomegalic leucopenia can not be sought in the distribution of the leucocytes in the different vascular regions, nor in any leucotoxic action on the part of the blood serum. He ascribes it to the condition of the blood producing organs, especially the bone marrow and spleen.

105. **Consequences of Saline Infusion After Nephrectomy.**—This article issues from Senator's clinic and is a contribution to the question as to the origin of hydrops renalis. Both kidneys were removed from rabbits and 1 per cent. salt solution or pure water was injected afterward. Among the various conclusions drawn from the results observed is that not all the molecules retained in case of insufficiency of the kidneys are of equal value in respect to the development of dropsy. When salt solution was injected whose percentage of salt was higher than that of the blood, the percentage of salt in the blood serum scarcely showed any rise, while the figures representing the osmotic pressure and the percentage of residual nitrogen showed a more or less marked rise. At the same time the refraction coefficient of the blood serum became reduced. It was evident that the main part of the retained salt was held in the juices and not in the parenchyma of the liver. Edema, hydrothorax and ascites were observed in nearly all the animals, more pronounced in the saline-injected animals than in those injected with water alone. It seems to have been established that certain organic substances contained in the residual nitrogen and the hydremic composition of the blood alter the walls of the vessels so that they become abnormally permeable for fluids. On account of these changes the masses of fluid which have gradually accumulated in the blood pass over into the tissues. An abnormal accumulation of fluid in the blood and lymph vessels first occurs in case of renal insufficiency when the salt accumulated in the vessels retains a corresponding amount of water. In advanced stages the insufficiency of the kidneys aids as a further factor in the accumulation of the water by direct disturbance also of the water-eliminating function of the kidneys.

107. **Bronzed Diabetes.**—Hess and Zurhelle conclude from their study of 2 cases that the cirrhosis of the liver and the hemochromatosis long precede the diabetes. They are independent of each other, but are probably all due to a single cause, some peculiar disturbance in the metabolism, possibly fostered by alcoholism. They accept Murri's theory that some permanent injury in the economy of the general metabolism leads to a general "dystrophy of the cells." This is manifested in the appearance of two abnormal properties, a capacity on the part of the tissues to take up the blood pigment (liberated by the enhanced destruction of the red corpuscles), and by a capacity for proliferation of the connective tissue, especially in the liver. The other abnormal property acquired is the reduction of the normal capacity for oxidizing carbohydrates (diabetes).

108. **Dilatation of the Colon.**—In pondering on the fatal termination in a case of dilated colon and sigmoid, Mülberger asks whether or not the patient, a boy of 13, might not have been saved by exclusion of the entire colon and an anastomosis between ileum and rectum. The disturbances are generally too slight to warrant such a serious operation, and when the syndrome becomes threatening it is usually too late for interference. The prospects for recovery would be much better if the diagnosis could be made in the early stages, when the dilatation is still within reasonable bounds. He remarks that there are about 80 cases of this disease on record. He recognizes two types, that with stiffening of the intestines, peristaltic unrest and excessive development of gas, and the form in which there is no peristalsis, the gas development does not surpass the normal range and the accumulation of fecal masses predominates in the syndrome.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be *made for review*, as dictated by their merits, or in the interests of our readers.

Scientific Memoirs. Officers of the Medical and Sanitary Departments of the Government of India. Issued under the Authority of the Government of India by the Sanitary Commissioner with the Government of India, Simla. Calcutta: Office of the Superintendent of Government Printing, India, 1902.

No. 1. Standardization of Calmette's Anti-Venomous Serum with Pure Cobra *Venom: The Deterioration of this Serum* Through Keeping in India. By G. Lamb, captain, I.M.S. and W. W. Hanna, Esq., M.B. Price, 3 annas (4d). From the Plague Research Laboratory, Bombay.)

ARE THE PROTEOLYTIC AND MILK COAGULATING EFFECTS OF GASTRIC AND PANCREATIC JUICE DUE TO ONE AND THE SAME ENZYME?*

JOHN C. HEMMETER, PH.D., M.D.

Professor of Physiology and Clinical Professor of Medicine, University of Maryland.

BALTIMORE.

The distinguished St. Petersburg physiologist, J. P. Pawlow, associated with S. W. Parastschuk, has published[1] a series of experimental investigations under the above heading. The view hitherto held and still held by most physiologists is that the proteolytic and milk-coagulating effects of gastric juice and pancreatic juice are due to specific enzymes. The earlier investigations on the subject date from Hammarsten.[2] In order to state precisely the direction of the inquiry, it is necessary to emphasize that Pawlow and Parastschuk attempt to prove that a separate and distinct milk-curdling enzyme does not exist, but that the milk coagulation is only a property of the pepsin. The *Fragestellung* here is not precise as might be desirable, for proteolytic and milk-coagulating effects might be conceived as attributable to one and the same proteid ferment, and yet pepsin and chymozin may be two different enzymes, for we may conceive that pepsin, the proteolytic enzyme, possesses also, to a certain extent, a milk-coagulating effect, which is only developed in an acid reaction and not in a neutral reaction, and, as far as human gastric juices are concerned, it can be stated that such an enzyme occurs which will curdle milk in the presence of an amount of HCl which, as a rule, is normal to human gastric juice (two parts per thousand), but will not curdle milk if the gastric juice is exactly neutralized. This disappearance of milk-coagulating power in the case of canine gastric juice, after it had been neutralized with sodium bicarbonate, was noticed by Pawlow and Parastschuk (p. 422), but they attributed this disappearance to a destructive effect of the alkalies employed, particularly to Na_2CO_3. When the juice was neutralized with $NaHCO_3$, the ferment could be preserved. To the destruction of the pepsin by alkalies they attribute their inability to separate these two enzymes by Hammarsten's method (shaking of gastric juice with magnesium carbonate, by which the pepsin is torn down by this insoluble powder), while the chymozin remains in solution. The *third and* fourth filtrates prepared in this way will coagulate milk energetically, but will not digest raw fibrin in twenty-four hours, not even if raised to the normal acidity. But Pawlow asserts that when this fibrin was diluted five to ten times its volume with 0.1 to 0.2 per cent. solution of HCl, the proteolytic effect on fibrin became distinctly evident.

The two enzymes, however, can be separated in a much simpler manner; by heating gastric juice to 65 degrees C. for ten minutes the chymozin can be destroyed. When chymozin is in solution together with HCl, three parts per thousand, the enzyme can be destroyed completely if the solution is kept at a temperature of 37 to 40 degrees C. for forty-eight hours.[3]. The pepsin is not destroyed by this process. In this manner a pepsin solution free from chymozin can be obtained. A solution of parachymozin free from pepsin can also be prepared in a similar manner.[4] Bang's investigations have made it very highly probable that the chymozin enzymes of different animals are by no means identical, but show striking differences in milk-coagulating power. Accordingly it becomes necessary in testing the results of previous investigators, to use the chymozin from the same animals as they employed.

In experiments with milk coagulation which extend over ten hours it must not be overlooked that milk may coagulate spontaneously when drawn and preserved under absolutely sterile conditions. Pawlow and Parastschuk, in attempting to demonstrate that proteolytic and milk-coagulating effects are attributable to one and the same enzyme, offer as proof of their assertion the parallelism of effects and proportionality of work done. The degree of proteolysis was measured in millimeters of a column of boiled albumin (Mett's method, devised in Pawlow's laboratory), and the degree of coagulating power was measured by the time that was required to coagulate 10 c.c. of milk by varying amounts of gastric juice. The coagulation of the milk always occurred in an acid reaction. The acidity of the various portions of the gastric juice was equalized by 0.5 solution of HCl. In Table 1, Pawlow[1] demonstrates that the least chymozin was secreted when the test food was milk (10 c.c. of milk coagulated in fifty minutes), and the most chymozin was secreted when the test food was bread (10 c.c. of milk coagulated in two and one-half minutes by the juice of the same animal). This same animal digested 5.8 mm. of albumin column (Mett), showing that the proteolytic power was very active also in the same bread juice. But in Table 2 we are told that a bread juice which digested 4.8 mm. did not coagulate 10 c.c. of milk until three minutes and ten seconds had elapsed, forty seconds longer than the previous juice, which had digested the same length of albumin column. In Table 2 the coagulation time is approximately the *same* for bread, meat and milk juice, 190 to 195 seconds, but the relative concentration of the ferments is placed at 1 for bread juice, 4.29 for meat juice, and 8.41 for milk juice. On page 419 the authors assert that this Table 2 shows a perfect proportionality of proteolytic effects and of milk-curdling power. The further efforts of these investigators were directed toward showing a parallelism of these two effects of gastric juice under the (a) influence of putrefaction of the juice; (b) the influence of heat (Table 5), and (c) the influence of chemicals, salts, bile and alcohol, etc. Similar experiments are then narrated concerning pancreatic juice obtained in various ways. It is interesting to learn that the pancreatic juice as secreted was inactive for curdling milk, and had to be activated by the addition of succus entericus and that the activation of the milk-curdling agent occurs at the same rate as the activation of the proteolytic agent, under the influence of succus entericus (enter-kinase).

On page 432 we are told that Table 12, which shows the proteolytic power and milk-coagulating power of juice (1) from the gastric pepsin glands, (2) from pylorus glands, and (3) from Brunner's glands, gives the evidence that the two powers correspond perfectly. Table 12, however, does not show this convincingly. In the second column of that table the proteolytic power is shown to shrink from 2.5 mm. (Mett) for pepsin gland juice to 0.5 mm. (Mett) for Brunner's gland juice. But the milk-coagulating time for pepsin gland juice is 27 minutes, for Brunner's gland juice is 18 minutes. In order to show an exact proportionality, the milk ought to have been coagulated in the same periods of time, as is shown in Table 2. But it is apparent from Table 12 that as the proteolytic power sank the coagulating power became intensified. Possibly an involuntary distinction is made between these two effects on page 439, where dilution is said to favor the proteolytic power, restoring it when it had been destroyed by the cold sodium acetate.[5] But, on the other hand, dilution is said to destroy the coagulative power. A reduced proteolytic power under the checking influence of salts, or dilution, does not necessarily indicate that the ferment is present in smaller quantities. It may be that the substance which is to be acted on proteolytically—the albumin or the fibrin—is so altered by the salts or other substances employed as to render them more insoluble. This can be demonstrated by performing experiments with known strengths of pepsin, allowing it to act first on ordinary pure fibrin, and then on fibrin which has been allowed to become saturated in a 20 per cent solution of sodium acetate. The proteolysis will be markedly less in the last case.

Hammarsten[6] objects to the main conclusion of Pawlow and Parastschuk that the two effects spoken of are due to one and the same enzyme, on the ground that two different rules exist, according to which these two effects depend on the quantity of ferments. According to Pawlow, however, the time of these reactions varies with the conditions influencing them. Some may accelerate and others may prolong the time of reaction. The chief conditions which he cites are alkalinity, acidity of the medium, and the degree of dilution. The authors recognize three rules under such conditions. A neutral solution of chymozin causes milk coagulation provided it is present in the solution in a certain definite concentration: (1) Then coagulation occurs according to the rule of inverse proportionality between the quantity of the ferment and the coagulation time; (2) when the chymozin is in acid solution the quantities of the ferment are inversely proportional to the square root of coagulation time, that is, the reaction is progressively accelerated; (3) when, in a very much diluted neutral solution of ferments, the quantities of the enzymes are proportional to the square of the coagulation time. These three varying conditions concern mainly the milk-coagulating power. In a similar way, Pawlow shows that the rules of the dependence of the effects of enzymes on the amounts of the enzymes can be influenced by external conditions. All such rules are reliable only within very narrow limits.

After reading the article as abstracted, we are justified in asking whether parallelism of effects and proportionality of work done in two different catalytic actions, really constitute satisfactory proof that the two actions are due to one and the same catalyzer. Pawlow and Parastschuk demonstrate that the proteolytic and milk-curdling effects of pancreatic juice show a parallelism and proportionality under varying conditions. But the same can be shown to be true of the amylolytic and fat-splitting power of pancreatic juice. Why, then, not assert that the amylolytic and lipolytic effects are due to one and the same enzyme also? Neilson[7] has shown that colloidal platinum, like lipase, can bring about hydrolysis and synthesis of fats. He also shows that this hydrolysis by platinum increases with the concentration of the platinum, increases with the temperature, is independent of the concentration of the ethyl butyrate, and that poisons[8] reduce the hydrolysis by platinum black. These same variations of effects, under the influence of concentration, temperature, poisons and salts, can be shown to exist with regard to the effects of a number of organic enzymes. For example, in the case of saliva it can be shown that the amylolytic action, the conversion of starch into maltose, is increased by concentration of the ferment, and by heat, but is injured by certain chemicals almost in the same manner as lipase is injured in its hydrolysis of ethyl butyrate (experiments of Loevenhart). If, therefore, we should execute a series of experiments in two series, one with colloidal platinum on ethyl butyrate under these varying conditions, and the other with saliva under varying conditions, certainly a rising or falling of the amount of catalytic work done, that is, a parallelism of effects, could not be asserted as proving that the two different effects are due to one and the same catalyzer in this case, for we know that two different agents are used in the experiments. The figures of the hydrolytic effect of colloidal platinum are given in the article by Hugh Neilson.[7]

When chymozin or rennet is separated from the stomach of a calf by Blumenthal's method,[9] an amorphous, white, gelatinous substance is gained, which greatly resembles aluminium hydrate in appearance. This precipitate is nearly pure rennet, and a very small portion of it speedily causes coagulation of milk. It has no odor or taste when prepared by this method, readily dissolves in water, and forms a clear solution. Blumenthal asserts that the same treatment will separate two enzymes from the so-called pepsin essences of commerce, and that the mother liquid from which the rennet is removed has no curdling action. The trypsin and chymozin of the pancreatic juice was separated by Roberts. A salt solution extract of a pancreas was slightly acidulated with HCl and kept at 40 degrees C for three hours. When neutralized, it was found that the trypsin had been destroyed, while the rennet or chymozin was unharmed.

W. D. Halliburton and Brodie draw a distinction between gastric and pancreatic rennet which has not been noted by previous observers. According to them the clotting indicated by pancreatic rennet is not a true coagulation, but a precipitation which takes place in a warm bath at 35 to 40 degrees C. The precipitate is finely granular and can not be detected by the naked eye. On cooling it to the temperature of the air, it sets into a coherent curd which can be again broken up by warming to 35 degrees C., when the granular condition returns, and the milk appears fluid. This may be repeated several times. Halliburton and Brodie call the proteid in this condition "pancreatic casein," and they say it can be converted into tyrein by gastric rennet.

The chymozins of different animals are not identical, and the chymozins of different organs in the same animal, as Halliburton and Brodie have shown, are not identical. The differences in the chymozins of various animals are considerable.[10] Most of the experiments with chymozin or rennet made prior to the publication of Pawlow and Parastschuk were made with the chymozin of the calf's stomach, and not until a comparative and quantitative study of the various chymozins has been made can it be proved that the milk-coagulating power of all chymozins is alike, or that this power is governed by the same rule with all forms of this ferment. Dilution, for instance, affects the milk-curdling power of chymozin from the pig in a different manner from the chymozin obtained from the dog. For comparing the effects of their chymozin with the results of previous investigations, it would have been necessary for Pawlow and Parastschuk to use the chymozin from the same animal.

Pawlow and Parastschuk, in attempting to prove that proteolysis and milk-curdling effects are due to one and the same enzyme, laid greatest stress on the demonstration of [illegible] of effects under various chemical and [illegible], and, secondly, on proportionality of work done. To subject a digestive secretion that gives evidence of two strikingly different effects to varying external influences, and thereby showing that the effects increase and diminish *together, or disappear* together, can hardly be considered a satisfactory form of experimental logic to prove that these two different effects are due to one and the same molecule. The work of these authors proves that the technic and method of experimentation may be objective and perfect, and yet the interpretation or subjective deduction therefrom may be unsatisfactory.

In order to make clear my meaning I will cite the example of two well-known digestive enzymes, the actions of which occur best in a mildly alkaline medium, ptyalin of the saliva, and trypsin of the pancreatic juice. Both trypsin prepared by Kühne's[11] method and ptyalin can be shown to be augmented and inhibited in their characteristic effects on fibrin and boiled starch, respectively, by temperature, by chemicals and poisons, by concentration and dilution. The amount of ptyalin and the amount of boiled starch in the one case, and the amount of trypsin and the proteid on which it acts, either fibrin or boiled egg albumin, can be so adjusted that a parallelism of effects and proportionality of work done can be

EXPERIMENTS WITH DOG SALIVA AND TRYPSIN (PANCREATIC JUICE), DEMONSTRATING EFFECTS OF INCREASE OF TEMPERATURE, ON DIGESTION OF BOILED STARCH AND ALBUMIN RESPECTIVELY.

Canine saliva and trypsin solutions were subjected in different and separate portions to the various temperatures stated in column 1, and thereafter their amylolytic and proteolytic power tested.

Temperature. Deg. C.	SALIVA.	PANCREATIC JUICE—TRYPSIN.
	Mm. of Boiled Starch Column Digested.	Mm. of Albumin Column Digested.

Both enzymes exhibit at first a slight increase of their characteristic effects followed by a gradual diminution until the enzymes are completely destroyed at 60° C., a parallelism of effects—which can also be demonstrated if both saliva and trypsin solution are *poured together and a starch*, as well as an albumin tubule, placed *in the combined solution simultaneously*. But here the action of amylopsin requires exclusion.

TESTS FOR ANY CHANGE OF ACIDITY VALUES IN THE GASTRIC JUICE ON STANDING AT ROOM TEMPERATURE.

Comparisons of work done by pepsin and chymozin of human gastric juices, together with quantitative determination of the free HCl and the total acidity. Gastric filtrates allowed to stand at room temperature for varying periods.

Notes.—1. Same gastric juice of Spencer when left in incubator at 36° C. began to lose its proteolytic power in 20 days. The milk-curdling power diminished more rapidly and *disappeared entirely on the* eighteenth day.

2. From Spencer a very large test meal was drawn, amounting to 760 cubic centimeters of gastric chyme, which was kept under experimentation 56 days.

3. In this table the figures show the proteolysis to diminish gradually from 8 mm. on January 3, to 4 mm. on February 28, but the milk-coagulating power diminishes much more rapidly and out of all *proportion* to the rate in which the proteolytic power diminishes. No parallelism in the diminution of these effects is here detectable.

shown to exist between these two ferments. If the same logic were applied to these phenomena as Pawlow and Parastschuk apply to milk-curdling and proteolysis, it would be equally possible to assert the amylolysis and proteolysis are due to one and the same enzyme, if it were not positively known that two definite enzymes were employed.

The method employed in Pawlow's laboratory to determine the degree of amylolysis is similar to that of Mett for proteolysis. Mett tubes are employed which are filled with filtered egg albumin coagulated in a water bath, and sealed at both ends with sealing wax. For amylolysis the tubes are filled with boiled starch in a similar manner. The diastasic power is expressed by the number of millimeters of boiled starch digested in a given time.

One of the most interesting facts discoverable during persistent analyses of human gastric juices is the total absence in some of them of the milk-curdling enzyme, while at the same time the peptic or proteolytic enzyme is present. This is proved by the fact that while the filtrate from test meals, consisting of bread and water, will not curdle milk, it will give the biuret reaction after it is added to discs of boiled egg albumin or to fibrin. This occurs in certain stages of chronic atrophic gastritis, when the milk-curdling enzyme disappears before the peptic enzyme. I have also seen it in two cases of cancer of the stomach. I must emphasize, however, that I have studied the gastric juice of two persons who are normal to all subjective and objective examinations. Into the stomach of one of these persons I poured a pint of milk, and withdrawing it by the stomach tube an hour thereafter it was in the identical condition in which it was poured down through the stomach tube. Nor did this milk coagulate after it was allowed to stand in an incubator for three hours. Nor could it be made to coagulate by the addition of varying amounts of calcium carbonate, nor by the addition of 1/10 normal solution of HCl added until the normal amount which be present in the gastric juice was reached. *Milk to which HCl is added* in this manner will coagulate when no enzyme is present, but it takes a much longer time. *Gastric juice which was boiled, and* thus had its enzymes destroyed, *did not coagulate milk any sooner* than a solution of HCl of the same strength. In testing milk coagulation on the addition of HCl, the time in which the coagulation occurs is an important factor in the determination.

The same persons whose gastric juice could not curdle milk produced a feeble proteolytic enzyme, for the filtrate from an Ewald test meal gave the biuret reaction. This conclusion is based on the assumption that the biuret reaction is an indication of the presence of peptones. These gastric juices, although they contain no free HCl, to the ordinary color test showed a feeble dissociation of methyl acetate by the Hoffman-Ostwald method of determining the free HCl. This probably indicates that the HCl may be so loosely combined with proteoses and acid albumin that it can readily dissociate and in the presence of pepsin produce peptones, though the ordinary color tests (Congo red, tropeolin(00) phloroglucinvanillin) are negative.

We had in these persons a demonstration of gastric juices: (1) That contained no free HCl, but combined HCl because they were capable of dissociating methyl acetate only slightly; but could form acid albumin and hemopeptone; (2) that could not coagulate milk; (3)

that gave the biuret reaction with an Ewald test meal. The conclusion seems justifiable that pepsin was present, but rennin or chymozin was absent, a conclusion which is difficult to harmonize with the view of Pawlow that the proteolytic and the milk-curdling effects are due to one and the same molecule.

As a further evidence of the differences between the chymosin of various mammalia, it should be stated that an antichymosin prepared by injecting the chymosin of the calf's stomach is not an antichymosin for the dog's milk-curdling enzyme. And, furthermore, an antichymosin (antilab) is not at the same time an antipepsin, that is, it does not arrest the proteolytic effect of the pepsin made from the stomach of the same animal from which the chymosin was prepared. If pepsin and chymosin (proteolytic and milk-curdling effects) were properties of the same molecule an antichymosin ought to be at the same time an antipepsin.

In their original article Pawlow and Parastschuk state that in their opinion chymosin acts synthetically, i. e., milk coagulation is the first stage toward the upbuilding of the new (native) proteid molecule; with this hypothesis they aim to bring their views in harmony with the modern idea of the reversible action of enzymes (Kastle and Lowenhart). Their viewpoint then is this: Pepsin and rennin (or chymosin) represent the same enzyme molecule—only pepsin acts analytically. Rennin (or the effect we attribute to the hitherto supposed rennin) is the evidence of the synthetic effect. Recently,[12] however Ernst Laqueur[13] has given the experimental evidence that chymosin or rennin acts analytically—i. e., splitting off a part of the casein molecule.

To Dr. R. A. Warner and Dr. J. Howard Iglehart, my associates, I am indebted for control analyses and tests in arranging above tables.

MINIMAL ALBUMIN REQUIREMENTS IN HEALTH AND DISEASE.*

L. BREISACHER, M.D.
Professor of Clinical Gastroenterology, Detroit Medical College;
Consulting Gastroenterologist, Harper Hospital.
DETROIT, MICH.

In 1891 I published[1] a series of experiments on the subject of the quantity of albumin necessary to keep a human individual in a normal nitrogen equilibrium.

At that time the quantity of albumin considered necessary for an adult in 24 hours was 118 grams, these figures resting on experiments made by Voit and his pupils.

I experimented on myself for a period of thirty days. The food, which was the same in quantity and quality for every twenty-four hours of the thirty days of experimentation, consisted of meat, rice, potatoes, bread, corn-starch, eggs, milk, sugar and butter, and contained 67.80 grams of albumin. The average quantity of nitrogen excreted in the form of urea by the urine, and estimated by the Kjeldahl method, amounted to 8.23 grams for every twenty-four hours, which, computed as albumin, amounts to 51.4 grams. This would leave 16.40 grams of albumin, or 2.62 grams of nitrogen unabsorbed by the gastrointestinal tract.

The organism, therefore, in these experiments, utilized 51.4 grams of albumin in twenty-four hours. Other experiments made at about the same period all tended to indicate that the figures of Voit, viz., *118 grams of albumin*, could be deviated from without any apparent inconvenience. Thus, in Rubner's experiments, but 38 grams of albumin were utilized in twenty-four hours for a period of three days, while in the experiments of Hirschfeld 35.4 grams of albumin were used per diem for a period of eight days. Other experimental corroborations offered by several other experimenters at about the same period might here be detailed, but the above are sufficient to prove that at least for periods varying from three to thirty days, the Voit figures of 118 grams of albumin, could be quite materially reduced.

Munk and Rosenheim, however, have offered, separately, experimental evidence that, at least in carnivorous animals, a decided reduction of the amount of albumin in the food for any great length of time, is followed by grave inanition.

Recently, Dr. Chittenden has revived the subject of the question of the minimal albumin requirements of the healthy man. Dr. Chittenden pursued his experiments on a large number of subjects, and extended them over a longer period of time. As in the experiments performed on myself, Chittenden found that the figures of Voit (118 grams of albumin) could be materially reduced without affecting the wellbeing of the individual.

In my paper already referred to it was contended that as long as an organism is in a state of nitrogen balance it is clear that neither the separate organs nor the entire system can be in disharmony as regards its nitrogen metabolism, and it follows from this that the quantity of albumin which is necessary to maintain an organism in a nitrogen balance, expresses at the same time the quantity of albumin which is at least necessary to repair the nitrogen waste of the fully developed organism.

These experiments are of interest to us not only from a physiologic and economic point of view, but also from a standpoint of practical therapeutics. Thus, for a number of years, I have made practical use of these facts where it is desired to reduce the albumin metabolism in Bright's disease, and where it is necessary to diminish excessive uric-acid production, which accompanies various diseases.

So, too, are these facts of importance where the degree of gastric albumin digestion is below the normal, and where it is desired to burden the stomach as little as possible with albuminous foodstuffs.

Likewise is this subject of significance in some cases of intestinal indigestion, with accompanying toxemic symptoms, although, unfortunately, our knowledge of the chemistry involved in this class of cases, is not as exact nor as precise as in cases of purely gastric origin.

Of significance also is the subject of minimal albumin quantity in connection with the criticism of the one or two meal a day fad, which is being so widely recommended by both lay and medical advisers. I say fad advisedly, for while there are some individuals with active digestion who thrive on two or even one meal each day, the average person, and particularly the great majority of stomach patients, fare much better where the food necessary in twenty-four hours is divided into a number of meals. In most stomach patients the question arises, how much or how little albumin should be ingested to meet satisfactorily the abnormal conditions of the gastric secretion and motility; and it is in these cases that the subject of minimal or maximal albumin quantity, and the number of meals necessary in twenty-four hours are of the utmost importance. A logical answer as to the number of meals we should take in twenty-four hours can only be given after making a thorough examination of the digestive and motor functions of the stomach; and it follows, therefore, that no absolute rule can be laid down which can be applied indiscriminately to every individual. It has been shown by experimentation that the average healthy individual digests the quantity of food required in twenty-four hours, more effectually and thoroughly, when it is divided into a number of meals than when it is taken at one time, and we also have learned by practical experience, as one would *a priori* expect, that in the stomach patient with weakened digestive action, this is even more true than in the healthy individual.

[1] Ueber die Groesse des Eiweissbedarfs beim Menschen. Deutsche med. Wochft., 1891, No. 48.

Further experimentation and observation will undoubtedly prove that the requisite albumin quantities necessary to maintain normal nitrogen equilibrium will more closely approach the figures of my experiments than those of Voit.

The occurrence of various digestive and metabolic abnormalities and deviations, both pathologic and physiologic, however, should warn us against an irrational acceptance and application of the minimal albumin figures.

I come in contact with scores of individuals who require large quantities of albumin to combat certain gastric abnormalities; and others, again, who likewise require an increased albuminuration in consequence of the existence of digestive and metabolic disturbances which make the normal fat and carbohydrate quantities inadmissible and injurious.

Again, there is another class of individuals which requires forced albumin feeding in consequence of the existence of some temporary or permanent condition of inanition.

It is evident, therefore, how fallacious an indiscriminate acceptance of the minimal albumin figures would be.

In fine, it may be said that while the experiments *on minimal albumin quantities prove that the average individual may and usually does eat too much albumin; and while probably 60 to 80 grams of albumin are nearer the normal requirement than the 118 grams of Voit, we should bear in mind that individual cases may require even much larger quantities of albumin than those called for in the Voit formula.*

THE FATIGUE OF COLD-BLOODED COMPARED WITH THAT OF WARM-BLOODED MUSCLE.*

FREDERIC S. LEE, Ph.D.
NEW YORK CITY.

Our knowledge of the physiology of muscle has been obtained chiefly through the study of cold-blooded animals. Especial stress has thus far not been laid on the fact that the muscles of certain animals are subjected throughout life to a moderately high and fairly constant temperature, while with others the temperature is usually much lower and variable.

The question has hardly been raised as to whether such different physical conditions connote different physiologic characteristics. *A priori* we might expect such to be the case, and the observations here reported actually demonstrate a difference in one respect, namely, in some of the physical phenomena of fatigue.

It is commonly believed that the main physical characteristics of the fatiguing, as distinguished from the fresh muscle, are a slowing of the whole process of contraction, which is manifested by a lengthening of the descending portion of the muscle curve; and a diminution in the lifting power of the muscle, which is manifested by a decrease in the height of the curve. This belief arose from a study of frog's muscle, where both these phenomena are pronounced.

Several years ago I called attention to the fact that the slowing in the process of contraction was shared in part by the phase of shortening of the muscle, as well as by that of lengthening. This phenomenon is manifested graphically on the ascending portion of the muscle curve by a progressive increase in the horizontal distance between the point of beginning and the apex and is most pronounced long before exhaustion has begun. It is far more prominent in turtle's muscle than in frog's, being there almost equally evident with the two other phenomena mentioned. At the same time I showed that a different picture is presented by the fatiguing muscles of the cat, inasmuch as with them neither the phase of shortening nor that of lengthening is slowed, as the lifting power is diminished. Here was a marked difference between the muscles of two cold-blooded animals on the one hand and those of a warm-blooded animal on the other.

The present paper deals with the question whether this difference is directly due to the temperature to which the muscles are customarily subjected.

Of cold-blooded animals, the frog and the turtle have again been studied, the gastrocnemius, the sartorius and the gracilis major of the former, and of the latter the coraco-antebrachialis profundus, the dorso-occipitis, the coraco-radialis superficialis, the pubo-tibialis, the ileo-fibularis, the ischio-caudali-tibialis. Some of these muscles are red and some white in color. In all cases the muscles were excised, suspended in a moist chamber, attached to a writing lever, subjected to a constant temperature, and stimulated electrically by single induction shocks, while the contraction curves were recorded by strictly isotonic methods. No fundamental differences were manifested by curarized and non-curarized muscles. In general, two temperatures were employed, a high and a low, of approximately 12 C. and 34 to 37 C., the latter being as high a temperature as can safely be employed without coagulating the muscle proteids. At the low temperature the customary phenomena of fatigue are present: Slowing of the phase of shortening, which is slight in the frog and pronounced in the turtle; slowing of the phase of lengthening, which is marked in both species; and diminution of the lifting power. The result is not fundamentally different when the muscles are subjected to the higher, practically mammalian, temperature. The two phases of the contraction process are quickened by the heat, but their slowing in fatigue is still present, phenomenally so in the turtle's muscles. These phenomena of fatigue are, therefore, in cold-blooded muscle independent of temperature. Furthermore, inasmuch as curarized and non-curarized muscles do not differ in these respects, the inference is justified that the phenomena in question belong to the muscle protoplasm rather than to the intrinsic nerve tissue.

Of warm-blooded animals, the cat, the rabbit, the white rat, the white mouse, the guinea-pig and the woodchuck have been studied, the muscles being the gastrocnemius and the extensor longus digitorum. It was found possible to treat the muscles in the same way as those of the cold-blooded animals. Since their nerves die very quickly, no curare was employed. Their muscle substance remains irritable for a sufficiently long time to enable excellent fatigue records to be obtained. At the temperature of the body there is a progressive dimi- in the height of the curves, with no lengthening of either the ascending or the descending portion. If, instead, the muscle be cooled to 12 C., and then fatigued, essentially the same result is obtained. There is, however, a broadening of the upper portion of the curves, indicating a tendency of the cooled tissue to linger in the contracted state; and this phenomenon, besides those above mentioned, is the most marked feature of the record of fatigue of the cooled mammalian muscle. While constantly present in the muscles studied, it is not sufficient to amount to a lengthening of the contraction process as a whole, with the single exception of the gastrocnemius of the white rat. In eight of the ten experiments performed with that muscle, careful measurement showed a slight lengthening, amounting in the maximum case to barely 0.7 of the original curve. This is almost a negligible quantity in comparison with the much greater lengthening exhibited by the muscles of both the frog and the turtle.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In view of the above facts, the following conclusions seem to be justified:

1. There is a physiologic difference between cold-blooded and warm-blooded animals in the mode of fatigue of their excised, voluntary muscles.
2. One of the characteristic phenomena of fatigue of the excised voluntary muscles of cold-blooded animals is a pronounced slowing of the whole contraction process manifested by a lengthening of the muscle curve. This is most pronounced at low temperatures. It is diminished, but not obliterated, at high temperatures.
3. The excised voluntary muscles of most warm-blooded animals fatigue without a slowing of the contraction process as a whole. At low temperatures there is observable a broadening of the muscle curve, caused by fatigue, which, in individual cases, may result in a minute lengthening of the curve as a whole.
4. The above facts suggest that the general physiologic differences between the muscles of cold-blooded and of warm-blooded animals are not due to immediate differences of temperature. The existence of a homothermal condition and the constant subjection of the skeletal muscle system to a uniform temperature, seem to impress on that system distinctive physiologic peculiarities.

College of Physicians and Surgeons.

LANDRY'S PARALYSIS.

WITH REPORT OF CASE.*

ROBERT McGREGOR, M.D.
SAGINAW, MICH.

To the pathologist and clinical observer, acute ascending paralysis is a malady of more than ordinary interest. For nearly fifty years it has been known and studied, yet little light has been thrown on the essential pathologic process which is the basis of this remarkable disorder. Since Landry, in 1859, wrote his classic treatise on the subject, many efforts have been made to work out a solution of the perplexing problem, but with far from uniform results. Reasoning from the association of a flaccid paralysis, with preserved electric irritability and absence of trophic symptoms, Gowers advanced the theory of a toxin acting on the arborizations of the pyramidal fibers in the anterior horns of the spinal cord in a manner analogous to the effect of curare on motor-nerve terminations in muscle. This hypothesis, however, has never been reinforced by the conclusions of other investigators.

There are good grounds for believing that bacteria or the products of bacteria or toxic elements elaborated within the body having a selective action on motor neurons play an important rôle in the causation of this disease. Streptococci, staphylococci, diplococci and rod-like bodies resembling those of anthrax and typhoid have been noted by competent observers in the spinal cord in typical cases. It is quite conceivable that a variety of toxins may have in common the property of exerting a more or less profound influence on motor neurons, just as there are several well-known substances, organic and inorganic, which possess this singular power. The precise way in which these toxins affect the integrity of the motor elements has not been definitely determined. Considerable difference of opinion has always existed as to whether the motor structures in the cord or in the peripheral nerves were the parts primarily subjected to the morbid change. Some authorities, notably Ross, have maintained that the affection is a peculiar form of multiple neuritis. This view is based, not on the clinical manifestations, but on the finding of degenerative changes in the peripheral nerves in certain cases. Such findings, however, are by no means frequent, and in many cases the most careful scrutiny has failed to disclose any histologic alterations in either the peripheral nerves or spinal cord. Perhaps the most constant features found postmortem in typical cases are acute enlargement of the spleen and engorgement of the lymphatic glands, especially those of the mesentery, conditions which clearly indicate the invasion of the system by a toxic principle. As far as the nervous system is concerned, wherever the primary point of attack may be, it is evident that the pathologic change is an extremely subtle one; and of late the assumption has been gaining ground that in all typical cases this change affects the gray matter in the anterior horns of the spinal cord. It is probable, also, that in cases in which the toxicant is exceptionally virulent involvement of the anterior roots may follow, and a neuritic condition be induced in the peripheral nerves as a later and secondary consequence.

In the last score of years many important advances have been made in our knowledge of the physiology of the nervous system. In the light of this knowledge we are often enabled to reason from symptoms to the exact site of the pathologic process. The light gleaned from such knowledge in typical cases of acute ascending paralysis leads us to suspect that the motor cells of the anterior cornua of the spinal cord are primarily, and perhaps in most cases solely, concerned in the morbid action, and that with improved staining technic it will yet be possible to render apparent cellular changes which can not now be made manifest. It is probable that whatever changes the motor cells undergo are of a transitory character and of a nature to affect temporarily their function only, since the majority of patients who recover do so completely. Etiologic facts support in a striking way the theory of a toxemic state or dyscrasia as an essential and antecedent condition. By far the greater number of recorded cases have followed in the wake of sundry infectious diseases, local or systemic disturbances of a septic character, or have been preceded by wounds, more or less trifling, which had served as points of infection. Some cases have been ascribed by certain authors to exposure to wet and cold, especially when this exposure was associated with alcoholism, but the precise way such causes operate is difficult to determine if we are to believe Landry's paralysis to be separate and distinct from multiple neuritis. If such causes were potent factors, it would be quite easily understood why most cases have been observed in males in the third decade of life.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

So closely do many cases parallel multiple neuritis that it is not always easy to distinguish between the two disorders. In typical cases the diagnosis is based largely on negative evidence. Thus, in Landry's paralysis there is generally an absence of pain or tenderness along nerve trunks and of sensory impairment, trophic symptoms or electric alterations. The mode of onset of paralysis, too, is distinctive, being, as a rule, more abrupt, speedily completed and more profound, a distinguishing characteristic being the progressive implication of groups of muscles, commonly from below upward, and never beginning in both upper and lower extremities at the same time. Perhaps the cases which offer the greatest difficulty are those in which peripheral neuritis, to a greater or less degree, coexists with the spinal lesions. Such cases may have so much in common with multiple neuritis as to render a positive diagnosis practically impossible. Landry's paralysis rivals acute anterior poliomyelitis in the rapidity of its onset, although in the latter malady the affected areas, as a rule, are more circumscribed and the muscles are paralyzed *en masse* rather than in successive groups. The nature of the paralysis has a close correspondence in the two conditions, being in both flaccid, purely motor and with abolished reflexes, the sole distinguishing point of difference being the presence or absence of changes in electromuscular excitability.

A remarkable feature of this strange malady is its extremely high death rate, contrasting sharply in this respect with both multiple neuritis and acute anterior poliomyelitis. The recorded results of several groups of cases occurring in this country and in Europe give a mortality varying from 50 to 80 per cent. In the majority of cases a fatal result follows within a week or ten days. The incidence of bulbar symptoms is of grave significance, death, as a rule, occurring from interference with the cardiac or respiratory centers. The occurrence of mental symptoms is of evil omen, as indicating a system especially susceptible to toxic influence or a high grade of virulence of the toxic agent. Recessions of mental or bulbar symptoms are hopeful indications. The degree of rapidity of onset and the degree of completeness of the paralytic condition may be taken as a criterion of the intensity or the severity of the pathologic process, and consequently of the comparative gravity of a given case. Recovery in favorable cases is always slow, but frequently complete. In protracted cases; the paralyzed limbs may or may not undergo atrophy. Considerable uncertainty exists on this point; doubtless because of the rarity of the disorder so few opportunities have presented for studying the disease in its later stages. In two rather protracted cases I have seen, the patients had become quite emaciated, but the muscles had preserved, unchanged, their electric irritability.

The following case which had been under my observation for a period of two years well illustrates the characteristic onset and symptoms of Landry's paralysis, besides presenting some peculiar phases of the affection which are interesting and suggestive:

Patient.—J. B., a young man, aged 23, was born and reared on a farm near Saginaw, Mich.

History.—There is nothing particularly noteworthy in either his family or personal history. He had been a moderate smoker, but never addicted to intoxicating liquors in any form. At the age of 10 he had been operated on for appendicitis. Early in the summer of 1901 he was employed as fireman on the steamer *Mecosta*, sailing between Cleveland and Lake Superior ports. On June 26, 1901, while at Fort William, he, in common with the rest of the crew, was vaccinated by the health officer of that port. A very sore arm followed, with considerable swelling of the glands in axilla.

Course of the Disease.—In a few days he became subject to chilly sensations, alternating with transitory spells of fever. He suffered, too, from occasional attacks of vertigo, and from rather profuse sweatings. In spite of these symptoms, he continued at his work all the way down to Cleveland, which was reached ten days later. Here he began to experience in the right foot a peculiar feeling of weakness, which gradually ascended the limb to the hip. In a few hours a like sensation was felt in the left foot, and steadily progressed upward. Recognizing that something was seriously wrong, he entered the Marine Hospital in Cleveland. Next day the condition of weakness in the legs had deepened into absolute paralysis. The arms soon began to suffer in a similar fashion, the right being first affected from the fingers upward. Within a period of eighty-four hours all four extremities were rendered powerless, with flaccid muscles and abolished reflexes. The paralysis of the arms was slightly less profound than that of the lower limbs, but he was unable to feed himself or to use them for any purposes whatever. Up till this time, and during the further progress of the case, there was an entire absence of pain, of nerve-tenderness in any degree and of sensory symptoms of every kind. There was no headache or mental disturbance. The functions of the bladder were not interfered with. At no time were there any edema, glossy skin or epithelial changes; nor were the coldness and lividity of the limbs, so often seen in anterior poliomyelitis, ever noticed. Before the end of the first week symptoms appeared indicating extension to the medulla. The lips became paretic, and the tongue, palate and throat were likewise affected, so that speech and swallowing became seriously impaired. Diplopia appeared and eventually convergent strabismus and ptosis. The heart, too, began to manifest disturbance of its rhythm, with slight dyspnea and occasional spells of tachycardia. So deplorable was the condition of things that a telegram was sent to the patient's father, urging him to come at once if he wished to see his son alive. On the father's arrival, he decided to take the boy home, and accordingly a journey of nearly 300 miles was made by rail, with the patient on a cot in the baggage car. He stood the trip very well, and after being for a time at home entered the Saginaw Medical College Hospital as one of my clinic patients.

During the period of several weeks the case exhibited no material change in any respect. Except at the stage of onset, the temperature was not elevated, but occasionally showed a subnormal tendency. He had no pain and no particular distress aside from the difficulty in swallowing, and the utter inability to move a limb or to express himself by the use of speech. He slept well and took a fair amount of nourishment, but his muscles had markedly diminished in volume, more, perhaps, than could be accounted for by mere disuse, yet a response, more or less prompt, could everywhere be obtained to the faradic current. After two months the bulbar symptoms began slowly to recede, and two weeks later the dysphagia, dyspnea, difficulty of articulation and ocular derangements had wholly passed away. The paralytic condition of the limbs, however, remained unchanged. No contractures or pedal deformities had occurred. The first sign of motor activity appeared three months after onset, and consisted of slight flexor movements of the left arm, the limb latest to become affected. Similar movements were soon possible in the right arm, and a little later in the left leg; the right lower limb—the first to become paralyzed—lagged considerably behind its fellow. The flexor groups of muscles, it was observed, manifested evidence of returning power very largely in advance of the extensors, which had to be reinforced by mechanical and electric stimulation. This lack of correspondence between flexors and extensors produced a condition of wrist drop and foot drop highly suggestive of multiple neuritis.

Treatment.—In the general treatment of the case reliance was placed on strychnia, iron, arsenic, the hypophosphites and glycero-phosphate compounds.

Result.—The most gratifying results seemed to follow from a simple solution of the glycerophosphate of iron, together with moderate doses of strychnia. The return of muscular power, however, was an extremely protracted process, nearly eight months having elapsed from the time of onset before the patient was able to stand unaided, and fully ten months before he could walk more than a few steps without fatigue. After a year, his strength improved more rapidly, but nearly all of the second year was required in regaining something like his former vigor. In June, 1903, after two years of illness, he entered on the duties of a mail carrier over an R.F.D route, a vocation he has since followed satisfactorily in all weathers without the loss of a single day.

Previous to his illness his usual weight was 165 pounds; since his illness his weight has never exceeded 135 pounds. He manifests at times a previously unusual tendency to trip over words in speaking. He still exhibits slight weakness of ankle on both sides, most marked on right. The knee jerks have thus far failed to return.

MULTIPLE NEURITIS.

WITH REPORT OF FOUR CASES.*

DAVID I. WOLFSTEIN, M.D.
CINCINNATI.

The principal interest in neuritis centers in the fact that, on the one hand, it resembles mere functional affections like neuralgia, which is a disease of the sensory nerve characterized by pain in the course of the nerve, or in its end distribution; on the other hand, it may be so extreme and grave in its manifestations as to be confounded with even the most serious affection of the cord itself. The term neuritis implies that there is an inflammatory condition of the nerve affected, though the diseased condition is not necessarily inflammation in its usually accepted sense, but may also be a degeneration, though with a tendency toward repair.

A neuritis, of course, may be confined to a single nerve when its symptoms will be those of the nerve affected.

As a matter of experience, however, we are more interested in that form of neuritis which affects many nerves simultaneously. This form we call multiple neuritis or polyneuritis. As regards causation, multiple neuritis follows various factors, which may be grouped as follows:

First. Toxic cases, due to the action of the poison derived from within the body. The poisons that produce most of the cases that we meet with are alcohol and mercury and lead, and occasionally arsenic; of course, there are many other toxic substances which produce this condition, but which will not be discussed here, as we see them less frequently.

Second. The second group is due to some agent acquired or developed within the body, that is, infectious forms which may accompany or follow most of the acute infections. As an agent which can give rise to this condition besides many other acute infections, especial attention should be directed to influenza, gonorrhea and the puerperal state. As a matter of knowledge, it is well known that the disease sometimes takes an epidemic form, beriberi.

Third. A large class of cases is due to general diseased states of the body, of whose origin we are not informed, such as rheumatism, acute diabetes, anemia, tuberculosis, syphilis, etc.

Fourth. There is another group of cases which followed exposure to cold or developed apparently without determinable cause.

As a type of neuritis due to alcohol, let me give the history of the following case:

Case 1.—Mrs. M., a young woman, aged about 30 years, who had been suffering for three or four months previously with very severe pains and with growing weakness in the extremities, called me to see her at a time when she was bedridden and unable to move the feet. She was very emaciated, her digestion was very much impaired, examination of the viscera revealed nothing abnormal except the heart action, which was very much accelerated, with very weak pulse. The pupils reacted promptly. There was no involvement of any of the cranial nerves. She complained greatly of extreme sensitiveness, but there was little numbness and tingling, though previously she had complained much of these symptoms. Pressure along the course of the large nerve trunks was painful. The muscles were relaxed and flabby, both of the arms and legs. The wrists and feet presented the well-known drop condition. The wrist drop was very marked, as was also the foot drop. As is well known, this wrist drop is due to a paralysis of the extensor muscles. The legs were very much emaciated and power was practically abolished. The paralysis was so complete in the lower extremities, with an inflammation of the spinal cord, that myelitis might have been suspected. A negative symptom of great importance was the absence of any interference with the function of the bladder or rectum, and another negative symptom, to which Star calls attention, was the absence of pain or anesthesia about the trunk. As is well known in the various forms of disease of the cord, like myelitis, or locomotor ataxia, such disturbance of sensation on the trunk is present frequently.

In making the diagnosis, the family history was taken into consideration, and a most shocking state of affairs was elicited. The husband was a confirmed drunkard and had induced his wife to follow in his evil tendency, and, in fact, a little child of this couple had also been taught to drink now and then. The patient had been drinking steadily for two or three years previous to the time I saw her. She finally developed a condition of mental confusion and uncertainty as to her whereabouts, and exhibited a certain hebetude of mind which is a very frequent accompaniment of severe forms of multiple neuritis, especially of the alcoholic type, and is known as Korsakoff's insanity.

There was great loss of memory of recent occurrences and much insomnia; later there were hallucinations of sight and hearing. The knee jerks were gone, as were also the ankle jerks. The paralysis began in the feet and legs, extending upward rapidly, and soon involved the arms and forearm. The muscles did not respond to the Faradic current, and when tested with the galvanic current showed the presence of degeneration.

Only a strong current elicited a contraction. There was great sensitiveness to manipulation, and the tactile sense was very much blunted. This case was so extreme and the general condition of the patient so depraved that all attempts at treatment were futile and death ensued, due to collapse.

Let me now give you an example of the milder form, in which the toxic agent was the poison of influenza, under the head of Group 2:

Case 2.—Mr. B. came to his physician's office complaining of great pain in the lower extremities, which had not yet become severe enough to prevent him from walking. This pain in the course of two or three days increased and there was pro preceded by wounds, more or less trifling, which had served as points of infection. Some cases have been ascribed by certain authors to exposure to wet and cold, especially when this exposure was associated with alcoholism, but the precise way such causes operate is difficult to determine if we are to believe Landry's paralysis to be separate and distinct from multiple neuritis. If such causes were potent factors, it would be quite easily understood why most cases have been observed in males in the third decade of life.

---

Recessions of mental or bulbar symptoms are hopeful indications. The degree of rapidity of onset and the degree of completeness of the paralytic condition may be taken as a criterion of the intensity or the severity of the pathologic process, and consequently of the comparative gravity of a given case. Recovery in favorable cases is always slow, but frequently complete. In protracted cases; the paralyzed limbs may or may not undergo atrophy. Considerable uncertainty exists on this point; doubtless because of the rarity of the disorder so few opportunities have presented for studying the disease in its later stages. In two rather protracted cases I have seen, the patients had become quite emaciated, but the muscles had preserved, unchanged, their electric irritability.

The following case which had been under my observation for a period of two years well illustrates the characteristic onset and symptoms of Landry's paralysis, besides presenting some peculiar phases of the affection which are interesting and suggestive:

Patient.—J. B., a young man, aged 23, was born and reared on a farm near Saginaw, Mich.

History.—There is nothing particularly noteworthy in either his family or personal history. He had been a moderate smoker, but never addicted to intoxicating liquors in any form. At the age of 10 he had been operated on for appendicitis. Early in the summer of 1901 he was employed as fireman on the steamer *Mecosta*, sailing between Cleveland and Lake Superior ports. On June 26, 1901, while at Fort William, he, in common with the rest of the crew, was vaccinated by the health officer of that port. A very sore arm followed, with considerable swelling of the glands in axilla.

Course of the Disease.—In a few days he became subject to chilly sensations, alternating with transitory spells of fever. He suffered, too, from occasional attacks of vertigo, and from rather profuse sweatings. In spite of these symptoms, he continued at his work all the way down to Cleveland, which was reached ten days later. Here he began to experience in the right foot a peculiar feeling of weakness, which gradually ascended the limb to the hip. In a few hours a like sensation was felt in the left foot, and steadily progressed upward. Recognizing that something was seriously wrong, he entered the Marine Hospital in Cleveland. Next day the condition of weakness in the legs had deepened into absolute paralysis. The arms soon began to suffer in a similar fashion, the right being first affected from the fingers upward. Within a period of eighty-four hours all four extremities were rendered powerless, with flaccid muscles and abolished reflexes. The paralysis of the arms was slightly less profound than that of the lower limbs, but he was unable to feed himself or to use them for any purposes whatever. Up till this time, and during the further progress of the case, there was an entire absence of pain, of nerve-tenderness in any degree and of sensory symptoms of every kind. There was no headache or mental disturbance. The functions of the bladder were not interfered with. At no time were there any edema, glossy skin or epithelial changes; nor were the coldness and lividity of the limbs, so often seen in anterior poliomyelitis, ever noticed. Before the end of the first week symptoms appeared indicating extension to the medulla. The lips became paretic, and the tongue, palate and throat were likewise affected, so that speech and swallowing became seriously impaired. Diplopia appeared and eventually convergent strabismus and ptosis. The heart, too, began to manifest disturbance of its rhythm, with slight dyspnea and occasional spells of tachycardia. So deplorable was the condition of things that a telegram was sent to the patient's father, urging him to come at once if he wished to see his son alive. On the father's arrival, he decided to take the boy home, and accordingly a journey of nearly 300 miles was made by rail, with the patient on a cot in the baggage car. He stood the trip very well, and after being for a time at home entered the Saginaw Medical College Hospital as one of my clinic patients.

During the period of several weeks the case exhibited no material change in any respect. Except at the stage of onset, the temperature was not elevated, but occasionally showed a subnormal tendency. He had no pain and no particular distress aside from the difficulty in swallowing, and the utter inability to move a limb or to express himself by the use of speech. He slept well and took a fair amount of nourishment, but his muscles had markedly diminished in volume, more, perhaps, than could be accounted for by mere disuse, yet a response, more or less prompt, could everywhere be obtained to the faradic current. After two months the bulbar symptoms began slowly to recede, and two weeks later the dysphagia, dyspnea, difficulty of articulation and ocular derangements had wholly passed away. The paralytic condition of the limbs, however, remained unchanged. No contractures or pedal deformities had occurred. The first sign of motor activity appeared three months after onset, and consisted of slight flexor movements of the left arm, the limb latest to become affected. Similar movements were soon possible in the right arm, and a little later in the left leg; the right lower limb—the first to become paralyzed—lagged considerably behind its fellow. The flexor groups of muscles, it was observed, manifested evidence of returning power very largely in advance of the extensors, which had to be reinforced by mechanical and electric stimulation. This lack of correspondence between flexors and extensors produced a condition of wrist drop and foot drop highly suggestive of multiple neuritis.

Treatment.—In the general treatment of the case reliance was placed on strychnia, iron, arsenic, the hypophosphites and glycero-phosphate compounds.

Result.—The most gratifying results seemed to follow from a simple solution of the glycerophosphate of iron, together with moderate doses of strychnia. The return of muscular power, however, was an extremely protracted process, nearly eight months having elapsed from the time of onset before the patient was able to stand unaided, and fully ten months before he could walk more than a few steps without fatigue. After a year, his strength improved more rapidly, but nearly all of the second year was required in regaining something like his former vigor. In June, 1903, after two years of illness, he entered on the duties of a mail carrier over an R.F.D route, a vocation he has since followed satisfactorily in all weathers without the loss of a single day.

Previous to his illness his usual weight was 165 pounds; since his illness his weight has never exceeded 135 pounds. He manifests at times a previously unusual tendency to trip over words in speaking. He still exhibits slight weakness of ankle on both sides, most marked on right. The knee jerks have thus far failed to return.

MULTIPLE NEURITIS.

WITH REPORT OF FOUR CASES.*

DAVID I. WOLFSTEIN, M.D.
CINCINNATI.

The principal interest in neuritis centers in the fact that, on the one hand, it resembles mere functional affections like neuralgia, which is a disease of the sensory nerve characterized by pain in the course of the nerve, or in its end distribution; on the other hand, it may be so extreme and grave in its manifestations as to be confounded with even the most serious affection of the cord itself. The term neuritis implies that there is an inflammatory condition of the nerve affected, though the diseased condition is not necessarily inflammation in its usually accepted sense, but may also be a degeneration, though with a tendency toward repair.

A neuritis, of course, may be confined to a single nerve when its symptoms will be those of the nerve affected.

As a matter of experience, however, we are more interested in that form of neuritis which affects many nerves simultaneously. This form we call multiple neuritis or polyneuritis. As regards causation, multiple neuritis follows various factors, which may be grouped as follows:

First. Toxic cases, due to the action of the poison derived from within the body. The poisons that produce most of the cases that we meet with are alcohol and mercury and lead, and occasionally arsenic; of course, there are many other toxic substances which produce this condition, but which will not be discussed here, as we see them less frequently.

Second. The second group is due to some agent acquired or developed within the body, that is, infectious forms which may accompany or follow most of the acute infections. As an agent which can give rise to this condition besides many other acute infections, especial attention should be directed to influenza, gonorrhea and the puerperal state. As a matter of knowledge, it is well known that the disease sometimes takes an epidemic form, beriberi.

Third. A large class of cases is due to general diseased states of the body, of whose origin we are not informed, such as rheumatism, acute diabetes, anemia, tuberculosis, syphilis, etc.

Fourth. There is another group of cases which followed exposure to cold or developed apparently without determinable cause.

As a type of neuritis due to alcohol, let me give the history of the following case:

CASE 1.—Mrs. M., a young woman, aged about 30 years, who had been suffering for three or four months previously with very severe pains and with growing weakness in the extremities, called me to see her at a time when she was bedridden and unable to move the feet. She was very emaciated, her digestion was very much impaired, examination of the viscera revealed nothing abnormal except the heart action, which was very much accelerated, with very weak pulse. The pupils reacted promptly. There was no involvement of any of the cranial nerves. She complained greatly of extreme sensitiveness, but there was little numbness and tingling, though previously she had complained much of these symptoms. Pressure along the course of the large nerve trunks was painful. The muscles were relaxed and flabby, both of the arms and legs. The wrists and feet presented the well-known drop condition. The wrist drop was very marked, as was also the foot drop. As is well known, this wrist drop is due to a paralysis of the extensor muscles. The legs were very much emaciated and power was practically abolished. The paralysis was so complete in the lower extremities, with an inflammation of the spinal cord, that myelitis might have been suspected. A negative symptom of great importance was the absence of any interference with the function of the bladder or rectum, and another negative symptom, to which Star calls attention, was the absence of pain or anesthesia about the trunk. As is well known in the various forms of disease of the cord, like myelitis, or locomotor ataxia, such disturbance of sensation on the trunk is present frequently.

In making the diagnosis, the family history was taken into consideration, and a most shocking state of affairs was elicited. The husband was a confirmed drunkard and had induced his wife to follow in his evil tendency, and, in fact, a little child of this couple had also been taught to drink now and then. The patient had been drinking steadily for two or three years previous to the time I saw her. She finally developed a condition of mental confusion and uncertainty as to her whereabouts, and exhibited a certain hebetude of mind which is a very frequent accompaniment of severe forms of multiple neuritis, especially of the alcoholic type, and is known as Korsakoff's insanity.

There was great loss of memory of recent occurrences and much insomnia; later there were hallucinations of sight and hearing. The knee jerks were gone, as were also the ankle jerks. The paralysis began in the feet and legs, extending upward rapidly, and soon involved the arms and forearm. The muscles did not respond to the Faradic current, and when tested with the galvanic current showed the presence of degeneration.

Only a strong current elicited a contraction. There was great sensitiveness to manipulation, and the tactile sense was very much blunted. This case was so extreme and the general condition of the patient so depraved that all attempts at treatment were futile and death ensued, due to collapse.

Let me now give you an example of the milder form, in which the toxic agent was the poison of influenza, under the head of Group 2:

CASE 2.—Mr. B. came to his physician's office complaining of great pain in the lower extremities, which had not yet become severe enough to prevent him from walking. This pain in the course of two or three days increased and there was progressive loss of power until patient was unable to walk and resorted to the bed. He was then referred to me about three weeks later, and when I saw him the legs could not be moved. There was much pain along the thigh and calves, the skin was very sensitive to touch, the patient could not flex the feet or the legs, and in attempting to extend or stretch the feet the very slightest pressure would overcome the effort.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The knee jerks were very feeble, but the muscles were not as yet atrophied; the distribution following the rule of multiple neuritis was quite symmetrical. The upper extremities were not involved. The patient was afflicted with an aortic lesion and developed at the same time a pneumonia, which ran a very irregular course. It was of the bronchopneumonia type and lasted about three weeks. There was no definite crisis. The neuritis ran a very favorable course, the knee jerks reappeared after about six weeks, although power and ability to move the legs slightly appeared before the knee jerks were re-established. It is rather peculiar for multiple neuritis following grip that the sensory symptoms are more pronounced than the motor symptoms and there is complete recovery usually within six weeks. The patient was able to move about, had perfect control of the legs, and there was no marked tendency to ataxia, although in the first weeks of my observation of the case there was some incoördination of movement. These cases of multiple neuritis following grip have been described by several writers, among them Mills and Star.

The third case which I wish to describe belongs to the third group, and was due to some condition of lowered nutrition of undetermined nature.

Case 3.—Miss W. was referred to me by Dr. Belt, of Milford, Ohio. Six months previous to the time I saw her she had had pain in the epigastrium and was treated for what was evidently ulcer of the stomach. There had been pain, tenderness over the epigastrium and also over the dorsal spine, vomiting, increased acidity and emaciation. Under appropriate medical treatment this condition was recovered from, but the patient was left in a very profoundly anemic state. She was brought to the city in a pitiable condition of exhaustion with very marked hysterical mental condition. She was extremely emaciated, the arms were but slightly involved as regards movement, although she complained of great pain and marked sensory disturbance, burning and tingling and numbness in the upper extremities.

The legs were completely paralyzed, the knee jerks and ankle jerks could not be obtained. The patient was unable to move the legs at all except from the hips, although there was a slight movement in the toes. There was no disturbance of function of bladder or rectum. There was no pain or anesthesia over the trunk. Tactile sensation was diminished over the legs on both sides, but not over the thighs to any extent, but pain and temperature sense were intact.

There was some loss of muscle sensation, that is, she did not know the position of the big toe when first seen. The patient was under treatment at Christ Hospital for three months and on forced feeding and very careful electric treatment, in conjunction with tonics and, of course, rest, a certain amount of power returned.

The muscles were still flabby and wasted, the response to the interrupted current was still quite feeble, and the galvanic current produced a slow wavelike response, indicating that recovery from degeneration had not yet persisted very far.

After a further three months the patient was so far recovered that she could walk around the room, with the aid of crutches, and weight had increased very much; all pain had disappeared. Her gait was very typical for multiple neuritis. On account of the weakness of the peronei and the anterior tibialis, she lifted the whole foot as if she were tripping over her own toes, so-called steppage. She is at present almost fully recovered. This case was so extreme that a suspicion of a cord lesion due to either pernicious anemia or to subacute inflammation of the cord was entertained; however, the character of the sensory disturbance, the evidence of slight power of movement and the preservation of bladder and rectum functions, combined with other symptoms, enabled me to exclude any other condition than a grave multiple neuritis.

The fourth case was one which I saw with Dr. E. W. Mitchell of Cincinnati, in consultation.

Case 4.—This was a little boy about 8 years old. There had been no previous history of infectious disease or of any other illness so far as known. The condition came on more or less acutely without any fever. The child complained bitterly of pain in the legs and arms, and pressure along the thigh and calves elicited shrieks. Attempts to move the legs produced great pain; the reflexes at the knee were absent. There was no evidence of any swelling of the joint, no redness, no fever. Acute rheumatism could be readily excluded.

The little patient was unable to walk, and I was informed that only the slightest motion was possible with the legs, though the arms were not involved to nearly the same degree. The involvement of both extremities, as well as lesser degree of involvement of the arms, the absence of marked wasting, the intact state of the sphincters and the absence of disturbance of sensation, except that of hypersensitiveness, enabled me to rule out in the case of this little child infantile spinal paralysis, both of the cord and of the brain, as well as myelitis. The disturbance was too marked, and the pain on pressure and on attempting movement was too pronounced to countenance a diagnosis of hysteria. I mention this because not infrequently in children we encounter cases of hysteria where no condition of paralysis is simulated.

I have quoted these four cases as fairly illustrating the different types of multiple neuritis. I do not wish to make this paper unduly long, but would like to call attention to some points in the differential diagnosis.

Neuralgia could generally be excluded, as the symptoms are sensory in character and never lead to paralysis, though sometimes there is inhibition of movement on account of pain, but it is not persistent. In nearly all cases of neuritis, even of single nerves there is an involvement of the motor fibers of the same degree as the sensory fibers. The presence of hyperesthesia and various forms of paresthesia is quite marked. The distribution of the anesthesia in well-developed cases corresponds to the distribution of the affected nerves as they course toward their periphery, and is unlike the distribution of the anesthesia of the lesions in the cord which occupies distinct zones or segments. The symmetrical distribution on the two limbs is also quite characteristic. Time is too short to take up the peculiarities in the distribution of the paralysis. This may come on quite gradually or so rapidly that within a couple of weeks the patient is helpless.

In some cases it does not advance to extreme feebleness. The extensors of the wrist and fingers and the peronei and the anterior tibial muscles in the legs are muscles first affected. It is only in very severe cases that the diaphragm or the facial muscles are involved. In my alcoholic case, above quoted, toward the end there was paralysis of the muscles concerned in swallowing. In children we must be careful to exclude infantile spinal paralysis, so-called anterior poliomyelitis. It must be remembered that as between myelitis and neuritis, if the attention be directed to the following points, the two need not be confused; in neuritis the function of bladder and rectum are maintained, girdle sensation is very rare, bed sores and cystitis likewise.

In neuritis a paralysis begins in the legs and forearms at the same time, and usually does not extend to the thighs and arms and rarely touches the trunk. It is only in the fatal cases that the abdominal and respiratory muscles are involved.

In neuritis the anesthesia is chiefly observed in the hands and feet, in the forearms and legs, and rarely reaches the arms and thighs. Tenderness in the nerves and muscles of the extremities belongs to neuritis, but not to myelitis. It ought not to be difficult to separate neuritis from locomotor ataxia. In practice it will be well to remember neuritis when attempting to establish positively the diagnosis of acute articular rheumatism, but in the latter the febrile course and characteristic appearance of the joints and the well-known tendency to the fugacity of the symptoms ought to prevent any confusion.

PROGNOSIS.

Except in the acute, grave cases, the prognosis is relatively very good. Of course, in those who are steeped in alcohol, lead or arsenic, with impaired constitutions, we can hope for less complete or no recovery. With patience and care a favorable prognosis may be pronounced in most cases of multiple neuritis.

TREATMENT.

Rest and appropriate nutrition and the removal of exciting cause wherever possible are the principal indications. In the early stages, when the disease has become well established, Star thinks well of the salicylates. The hyperesthesia should be combated by wrapping the parts in wool or light bandages or by applying soothing applications. Malaria, syphilis and lead require the usual treatment.

In alcoholics much skill is required in controlling the amount of alcohol that should be given and determining when it should be withdrawn. Where there is any chronic condition I agree with Star that we obtain the best results from strychnin, arsenic and the glycerophosphates, gentle massage, warm baths, electricity, and only the galvanic current should be used. The object of these latter remedies is, in the first place, to prompt a repair of the diseased nerves and to keep the muscles in a state of good nutrition while such repair is taking place.

The object of this paper has been to call the attention of the profession more particularly to this form of inflammation or degenerative changes in the nerves and to point out in a brief way the characteristic features of multiple neuritis as distinguished from disease of the spinal cord.

DISCUSSION

ON PAPERS OF DRS. M'GREGOR AND WOLFSTEIN.

Dr. H. T. Pershing, Denver, reported briefly two cases which he saw recently and which had some bearing on the subject. In one case the patient began to have the unmistakable symptoms of multiple neuritis affecting both legs below the knees, with severe pain, preventing sleep at night, and gradual weakening of the muscles, with no disturbance of the bowels or bladder, and no affection of the trunk or of the arms. It was recognized as a case of multiple neuritis, but it was quite difficult to find the cause. The man was a metallurgist and had invented a process for the separation of different kinds of ore. That led his physicians to suspect that arsenic might be the cause of the symptoms, especially as the arms were not involved and the pain was prominent. Examination of the urine showed that the man constantly eliminated a small quantity of arsenic. Very small doses of iodid of potassium seemed markedly to increase the pain, so that he objected very decidedly to taking it. The family physician and Dr. Pershing both thought at first that this might be imaginary, but they came to the conclusion that it was not, and that the increase in the pain could be explained as Gowers explains the aggravation of the symptoms due to mercurial poisoning, as when iodid is given it makes the metal more soluble. This man made a complete recovery, although he had to be kept away from the ores that contained arsenic. In the other case, a man whose character was in general irreproachable, during the first week in July did an unusual amount of muscular work; he carried some boards, sweated profusely, and was rather exhausted by the heat. On the Fourth of July he was with some friends, and they drank a considerable quantity of beer, which he said was stale, and ate some lobster. He had a very severe attack of acute indigestion; he vomited and showed every indication of ptomain poisoning, and the prostration was great. Before he recovered from that attack, which lasted two or three days, he noticed a weak, heavy feeling in the legs, which gradually developed into numbness and very pronounced weakness, so that about two weeks later, when Dr. Pershing saw him in consultation, he had the typical symptoms of multiple neuritis, and was barely able, with the greatest difficulty and pain, to walk about the room. The arms were slightly affected and there was some paralysis of the wrists and fingers. The prognosis seemed favorable and he made a steady and complete recovery. About a year later the knee jerks were normal.

Dr. D. R. Brower, Chicago, said that in acute Landry's paralysis his observations have led him to suppose that the great majority of cases so diagnosed are cases of multiple neuritis. He thinks that too much importance is sometimes attached to the condition of the bladder and rectum in differentiation. He has seen cases in which for a time control of both of these functions was lost, and in which the subsequent history made the question of diagnosis of multiple neuritis very easy. This is especially true of cases in which there is some mental disturbance. While it is undoubtedly the usual condition that the motor and sensory symptoms go hand in hand, yet there are cases in which there is an entire absence of sensory symptoms, and these cases are by no means rare. There is a form of multiple neuritis that requires more attention on the part of the profession than it has so far received; that is beriberi. In the republic of Panama in December, 1904, it was one of the principal causes of death, and it prevails to a very large extent in all our recent territorial acquisitions. Dr. Brower has seen a few cases in which recovery seems to have been promoted by large doses of quinin in connection with strychnia. The cause of death in Landry's paralysis, as in multiple neuritis generally, is circulatory and respiratory failure, and he thinks that all the cases should be very carefully watched with reference to these important functions and timely aid given. The next important principle in treatment is careful attention to elimination.

Dr. William House, Portland, Ore., asked Dr. Wolfstein whether the use of antitoxin has increased or decreased the number of cases of postdiphtheritic neuritis.

Dr. H. G. Brainerd, Los Angeles, asked Dr. Wolfstein whether or not in those unfortunate cases which resemble Korsakow's insanity he noted any falsification of memory, as well as loss of memory. The difficulty of making a diagnosis is great in certain cases. Dr. Brainerd remembered watching with interest a case in which there was a question as to whether or not it was ordinary chronic neuritis or leprous neuritis. It was nearly a year before it was decided that it was a case of leprous neuritis. Dr. Brainerd watched the case for a period of six or seven years, during which time the disease did not make much progress, and no other evidence of leprosy was shown. Recently he had under his care a patient with multiple neuritis, not a young man, whose occupation, that of a cement contractor, kept him out of doors most of the time. He was of such rugged build that he would not be supposed to be susceptible to changes in the weather. For several years he had been in the habit of using bromo seltzer daily. When Dr. Brainerd first saw him, two weeks after the beginning of the attack, his face was purple and his finger nails were blue. As there had been no unusual exposures to inclement weather, and he could learn of no other cause, Dr. Brainerd believes that the toxic effects of the bromo seltzer were the cause of the neuritis. Recently he saw a case of neuritis in a Baptist deacon just past middle life, and who, from his connection with the church, might be supposed to be beyond reproach. Thinking that the man might be in the habit of taking something containing arsenic or alcohol, Dr. Brainerd asked if he were using anything of the kind, at which the family became very indignant, but the man finally admitted that he was in the habit of taking a bottle of vinegar bitters every day or two, and had been for a period of many months. This was undoubtedly the cause of his neuritis.

Dr. H. A. Tomlinson, St. Peter, Minn., called attention to the fact that bromo seltzer is said to contain acetanilid.

Dr. Robert McGregor, Saginaw, Mich., thinks it is desirable that such cases should be reported and postmortem findings recorded wherever possible. The systematic study of a satisfactory series of cases would enable physicians to know more clearly the line of demarcation between Landry's paralysis and multiple neuritis. It is, of course, absurd to suppose that cases of this character should conform to any conventional type. There will be considerable variations, but there are three points which Dr. McGregor believes are fairly constant and which serve as guides in the diagnosis of any form of Landry's paralysis: 1, The toxic element as a causative factor; 2, the implication of the motor elements of the spinal cord; 3, rapidly ascending paralysis and, in rare cases, descending in character—a paralysis which is flaccid and purely motor and in which the electric irritability of the muscles is little, if at all, changed.

Dr. David Wolfstein said that a diagnosis of Landry's paralysis should not be made simply because of the severity of the symptoms. He declared that it is unfortunate that the profession has departed so far from the ideas of Landry. If one would stick to Landry's original definition of the disease as one involving only the motor nerves and rapidly ascending, very often occurring in cases in which there is no disturbance of sensation, there would be less confusion. Dr. Wolfstein said that Dr. Brower's criticisms are hardly justified. In these cases of neuritis accompanied by insanity there was no actual loss of function of the bowels or bladder. In reply to a question, he stated that there is no doubt that since the use of antitoxin the number of cases of postdiphtheric paralysis have greatly decreased.

PHYSICIANS AND PROPRIETARY MEDICINES.

HENRY P. LOOMIS M.D.

Professor of Therapeutics and Clinical Medicine, Cornell University.

NEW YORK.

There are several particularly objectionable features connected with the proprietary medicine evil, to which [illegible] desirable to call attention with a view to securing [illegible]operation of the great body of practicing physi[illegible]n obliterating them so far as possible. Every one [illegible]nowledges that a great number of secret proprietary medicines are utterly worthless and, in fact, harmful; hence all preparations which do not emanate from thoroughly reputable firms should be viewed with reserve—if not actual suspicion—until they have been examined by competent, unbiased men.

It should also be remembered that the testimonials given are often of questionable value, because physicians and professors in certain medical colleges may sometimes be induced to give testimonials on insufficient knowledge. Finally, attention should be called to the well-known fact that mystery exerts a strong influence on the average mind, and a form of mystery may be said to be the chief stock in trade of many exploiters of the clap-trap compounds, now widely used.

While there are many manufacturers who are doing valuable work—and to them this criticism does not apply—there are hundreds of men, anxious to occupy the profitable field of proprietary medicine manufacturing or exploiting, but wholly lacking the ability and desire to pursue original research, who merely resurrect obsolete remedies, dress them anew in garb and name, and claim for them properties as marvellous as those of Aladdin's lamp.

Others use some well-known *substance, acetanilid,* for instance, as a basis for compounds with pseudo-scientific names, claiming entire originality and extraordinary therapeutic properties for their products. It is truly amazing that these compounds should have attained such wide use by physicians in view of their potency for harm and the extreme simplicity of the acetanilid test.

Manifestly, every physician owes it to himself and to his patients to recommend only such preparations as are attested by men whose reputation for solid attainment and integrity is beyond question.

It is hardly necessary to say that no one is justified in prescribing any remedy before he has satisfied himself of its clinical nature and pharmacologic action, so far as can be learned. There are so many trained clinicians in the hospitals who have excellent facilities for intelligent tests—so many pharmacologists with elaborate equipment, devoting all their time to laboratory investigestations, that there is no excuse for the manufacturer seeking testimonials from those who are not in a position properly to test the effects and efficacy of so-called remedies.

It is perhaps in regard to the third point, that of mystery, that the warning is to be most strongly presented. The busy practitioner is unable to keep pace with the rapid additions to the terminology of the various branches of medical science, such as the Ehrlich theory of immunity, hence he becomes accustomed to reading articles by men of repute, which may not be perfectly intelligible to him, and later he accepts with equal readiness the statements of nostrum vendors, who, adopting the terminology but not the meaning of science, give pretended concise descriptions of the methods of preparation of their own wares, in mere word jumbles, intended to impress the unwary, while the facts which are the essential ones, viz., the success of the medicine in the treatment of disease, are stated with more apparent child-like simplicity than veracity. To show how this truly astounding fraud is frequently perpetrated, I mention the following:

Circulars of three proprietary remedies, which have been widely distributed among physicians, and which pretend to give most concise details of preparation, involving processes of metabolism, actions of enzymes. etc., were submitted to three well-known physiologic chemists with a request for a perfectly simple explanation of the reading matter. The answers were essentially similar in each case, and were to the effect that the pretended concise descriptions were largely mere word jumbles devoid of meaning, or else a tissue of falsehood.

Can the average physician discern truth in that which is false or meaningless to the expert?

How the conspirators must laugh at the ease with which they can dupe educated men with gibberish, while pretending to appeal to their profundity!

It is as easy to use intelligible and simple language in describing the method of preparing an article as it is in stating clinical results, and every physician should refuse to be influenced by an advertisement which he can not readily understand, and which for that very reason may be making a bid for our too ready credulity.

Medical Ethics.—The dissatisfied persons who wish to discharge their medical attendant and employ you, will sometimes contend that the rules relative to taking charge of patients, recently under care of another physician, are harsh and unjust, and peculiar to the medical profession. Neither of these statements are true, for our custom is identical with that which prevails everywhere among all classes of people, which requires the formal discharge of the old employé before a new one can take his place. Besides, no person, whether menial, mechanic or physician, can fill a vacancy till one exists.—Hart, in *Journal of Kansas Medical Society.*

THE NOMENCLATURE OF PROPRIETARY MEDICINES. THE CRUX OF THE SITUATION.*

C. S. N. HALLBERG, Ph.G., M.D.
Professor of Pharmacy, School of Pharmacy, University of Illinois, CHICAGO.

It is related of an old-time country practitioner, in a southern state, who not only had faithfully served the community in attending to the first arrivals, but also had usually been called on to name the little newcomers, that his patience finally became so exhausted that when appealed to in an especially urgent case, he petulantly retorted, "Oh name the twins Belshazzar and Beelzebub!" "Oh pa!" gleefully shouted the mother, "the doctor has named the babies Belshazzar and Beelzebul!" "Wal!" responded the fond father, "if the kids be only as good as their names they will be all right!"

The incident may or may not be true, as it may or may not have any bearing on the naming of proprietary medicines. Let us see. The names looked imposing and mysterious, they had a suggestive and familiar sound, possessed a peculiar euphony, and in this case were thought proper names because the persons using them did not know what they meant or what they stood for.

MULTIPLICATION AND SIMULATION.

Is there any difference in the methods of naming the vast majority of proprietary medicines? Take a few examples:

Aseprol
Aseptol
Aseptolin
Aseptin

Albargin
Actol
Argentamin
Argentol
Argonin
Collargol
Ichtargan
Itrol
Largin

Hematin
Hematogon
Hemoferrogen
Hemoferrin
Hemoform
Hemogallol
Hemol
Hemorrhol
Hemostate
Hemotrophine

Lyptol
Lysol
Lysetol
Lycorin
Lygosin
Lysidin
Lysitol
Lysoform

Bromalin
Bromamid
Bromolein
Bromidia
Bromipin
Bromol
Bromopyrin
Bromosin
Bromphenol

Dermatin
Dermatol
Dermogen
Dermol
Dermazon

Iodipin
Iodocrol
Iodoformal
Iodoformine
Iodoformogen
Iodoformsalol
Iodogenol
Iodolen
Iodolin
Iodophenin
Iodosin
Iodosolvin
Iodothyrin

Ferratin
Ferratogen
Ferrhemin
Ferrinol
Ferripton
Ferroleum
Ferropyrin
Ferrosol

Salacetol
Salacetin
Salifebrin
Saliformin
Saligallol
Saliphene
Salit
Salophene
Salochinin
Salocoll
Salocreol
Salol

Tannalbin
Tannalborin
Tannapin
Tannformal
Tannigen
Tannipyrin
Tannoform
Tannochrom
Tannocoll
Tannopin
Tannosol

LACK OF SYSTEM.

Is there anything to suggest that a system or plan has been followed in naming these any more than in the naming of apartment houses, sleeping cars or breakfast foods? Names of the latter often rival those of proprietary medicines, the following examples having been observed recently: A house called "Eudoxin," for a well-known synthetic; "Quantzinteco-matzin," the name of a sleeping car on the Oregon Short Line, might be a new name for hexamethylene tetramin, and "Apetizo," the iron food, may be mistaken for apetol, the strengthener that strengthens, a wonderful discovery composed of *Nux vomica, Gentiana purpurea, Calumba jatcorrhiza, Quassia amara lignum, Prunus virginiana, Prinus verticillatus, Simaruba amara, Spiræa tomentosa, Cinchona rubrum, Sumbul moschatus,* aurantii cortex, aromatics, vinum xericum fortior; the "tonic that tones"; that "gives birth to an appetite"; made in Danbury, Conn., which in former times was famous through "Newsman" and as the home of "Synthetic Myristica," but is now devoted to the exploitation of the medical profession through a medical journal with half a dozen anonymous pseudo-chemical companies on the side.

CONFUSION WORSE CONFOUNDED.

Besides these there are preparations entirely distinct in character, with names almost similar, e. g.:

Mercauro, Mercurol, Mercuriol.
Euphorine and Europhene.
Papain and Papin
Benzosol and Benzozon.
Glycozone, Hydrozone and Liquozone.

The last illustrious trio have demonstrated the dangers to the manufacturers in selecting names in the present haphazard, slipshod manner. The proprietor of the first two of the three alleges that the name of liquozone is unwarranted and misleading, and liable to confusion with his own. The liquozone proprietors charge business rivalry as the sole motive for the accusations against their famous germicide

"Normalin" is a serum preparation of arsenic, administered internally in teaspoonful doses, for which formalin is liable to be dispensed, and "Lavolin" is the trade name for liquid petrolatum, exploited as the solvent for agents recommended in spray medication exclusively in a certain work on rhinology. Pharmacists who have never heard of lavolin naturally dispense lanolin instead, and thus innocently became partners in the absurdity of causing a sufferer to try to accomplish the feat of spraying an ointment through an atomizer.

SCIENTIFIC NOMENCLATURE.

It should be needless to point out to men engaged in any scientific pursuit the necessity for a scientific nomenclature. Without systematic terminologies, the sciences contributing to pharmacy can neither be studied nor learned. What botany, pharmacology or chemistry would be without scientific nomenclatures is best answered by remembering what they were before such were evolved by Linneus, Fluckiger and Berzelius. What progress was made in medical science until systematic terminologies were introduced in physiology, pathology and anatomy? Science is *universal*; without a universal language it can not progress. It is a fundamental object and purpose of all sciences to establish a universal language through more or less systematic terminologies. To deny the necessity for nomenclature in pharmacy is to deny that it is a science. But what are the facts? Pharmacy, or at least its original votaries, aided in developing terminologies, and in two of *Myrm*sciences named the modern nomenclature connection that *Myrm*acists.

tige of tradition and almost universal harmony, but is fortified through legal enactments in every country in the world. Each of the thirty different classes of preparations of the Pharmacopeia has a distinct meaning, and with those additional in the National Formulary they afford nearly every form in which medicinal agents may be desired. Why are they ignored? Have the terms aqua, liquor, spiritus, elixir, tinctura, fluid extractum lost their meaning? Do the old names, pulvis, pilula, etc., sound too commonplace; or is it that their simplicity would be incompatible with the claims of originality or novelty or wonderful therapeutic virtue of the products of these *début de siècle* ideas? Or, perish the thought, is it that the manufacturers are not acquainted with pharmaceutic terms, or do not know of the existence of the Pharmacopeia?

THE MOTIVES.

Possibly, probably the scientific terms are ignored in order to impose more easily on physicians, to pander to their convenience and lassitude, to secure monopoly of products through trade-marks, to intimidate pharmacists with the cry of substitution, and, finally, to exploit the public with cure-alls.

Take these well-known proprietary medicines originally advertised to physicians exclusively:

Antikamnia	Pepto-Mangan
Bromidia	Scott's Emulsion
Fellow's Syrup	Vin Mariani

Would they have gone to the public if they had been known under the following titles, with the name of the manufacturer or other device as a trade-mark to indicate the brand?

Pulvis Acetanilidi Compositus.
Mistura Chloralis et Potassii Bromidi Comp.
Syrupus Ferri Mangani Quininæ et Strychninæ Comp.
Liquor Ferri et Mangani Peptonatus.
Emulsum Olei Morrhuæ cum Hypophosphitibus.
Vinum Erythroxylon.

While only two of the above, antikamnia and Scott's emulsion, are advertised directly to the public. all, except bromidia, are used for counter and pyramid window display by "cutters" and department stores.

TRADE-ADVANTAGE DELUSIONS.

Intelligent physicians are beginning to realize that they may just as well prescribe peruna and other "patents" at once as to patronize proprietary medicines with trade-names. Many also refuse to prescribe any trade-name article for fear that they, or the pharmacist, may confuse the names and serious results may follow. And yet, in the face of this undeniable awakening of medical men, a firm of chemists of the highest standing has recently devised the following meaningless, empiric names for three articles of its manufacture: Duotonal tablets, quartonol tablets, sextonol tablets.

"Tonol" stands for glycerophosphates, and the prefixes refer to one number of different kinds of glycerophosphates, salts of alkalies, contained in each tablet. Now, these names have been devised on the assumption that physicians will appreciate them, owing to their brevity
and euphony, ure the other hand, it is evident that these
names for them properties the thinking physicians, as
Aladdin's lamp. eutical titles, with the name

scientific names, claiming entire me distinct sym-
traordinary therapeutic properties for d to the scien-
It is truly amazing that these compounds a brand or
attained such wide use by physicians in vi

make of a product. When, however, a symbol of universal significance and profoundly reverent traditions is through a sordid judicature permitted to become the trade-mark of a particular line of manufacture, the necessity for some scientific system for the selection of trade-marks becomes evident.

The protection of the public is the primary object of a trade-mark; to aid the purchaser in distinguishing the brand or "make" he desires from all other brands or "makes." Naturally, it is the maker's highest prerogative to protect the public in its right of selecting his brand. What should he choose for this distinctive designation rather than his own name—his as against the world?

But greed and avarice lay their vandal hands even on the symbol of the ancient republic of Helvetia, and trail this venerated emblem in the dust of venal trade, by the grace of the state of New Jersey. The public must be protected against such vandalism; the medical profession is finally beginning to realize its anomalous position, and mindful of the dangers of Scylla and Charybdis, will soon refuse to recognize trade-names for medicines, and the pharmacist—well, he is familiar with the fact that the highest ethically exploited trade-name article keeps company in the price lists of wholesale druggists with Lydia Pinkham, peruna and Pierce of Buffalo. The wholesale druggist is the only purveyor of medicines whose fiduciary frame of mind realizes that all articles with trade-names are primarily designed for trade.

THE REMEDY.

Since none of the parties mostly concerned, the public, the physician or the pharmacist, desires the perpetuation of trade-names, why should the manufacturers be allowed to use them; or rather, why should not physicians and pharmacists refuse to handle any trade-name article? Although this position may be brought on through agitation and education, the process will be too slow. The thing to do is to carry a case for infringement of a trade name to the Supreme Court of the United States and get a decision in line with former cases, such as castoria and syrup of figs, which will once and forever prevent exclusive use of a coined name for a medicine when there is no other name by which such article may be designated. The nomenclature is the crux of the proprietary medicine question; its reformation will be a boon to the physician and the salvation of the pharmacist.

THE DENTITION OF MAMMALS WITH REFERENCE TO THAT OF MAN.*

H. W. MARETT TIMS, B.A., M.D., C.M.
Demonstrator of Anatomy in the University of Cambridge; Lecturer on Biology and Comparative Anatomy, Charing Cross Hospital Medical School (University of London).
LONDON, ENGLAND.

In response to the kind invitation of your president, I have ventured to bring before you some of the results of recent researches into the tooth-genesis in mammals including that of man. Though my work on primate dentitions is still incomplete, I shall endeavor to summarize some of the problems to which I am paying particular attention, in the hope that an appreciation of the gaps in our present knowledge may suggest lines of investigation to other workers.

Before homologies and methods of tooth replacement can be adequately interpreted it is necessary to have a clear idea of the number of dentitions represented in the *Mammalia.* The introduction by Owen of the terms "monophyodont" and "diphyodont" indicated the state of knowledge in his day, but with the application of histologic methods to the problems of comparative odontology, the words lost much of their original significance. The marsupials, regarded by Owen as monophyodont, were shown by Kükenthal to be really diphyodont since there were down-growths of the dental lamina to the lingual side of the functional teeth, a potential second series which, however, never become functional. The result of this discovery was to interpret the functional teeth of marsupials as belonging to a persistent milk series. This view became current and is still to be found in all text-books. Subsequently, in the light of this interpretation the lingual rudiments, discovered by Leche in *Myrmecobius,* were regarded as prelacteal. Thus marsupials are now known to possess representatives of three dentitions, the middle series alone cutting the gum and usually regarded as a persistent milk dentition, but which to my mind is capable of another and more satisfactory interpretation.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Downgrowths of the dental lamina, similar to those found by Kükenthal in *Didelphys* have been discovered in a number of other mammals in which two sets of teeth are functional, e. g., man, dog, seal, hedgehog and others. The number of instances in which such post-permanent vestiges exist, warrants the belief that they are of very frequent, if not universal occurrence.

Apart from the doubtful interpretation of the so-called prelacteal vestiges in the marsupials, such are definitely known to occur in other mammals with two functional dentitions, for example in the pig and in man. In the latter they were first discovered by Röse. I have also noted their existence and they are shown in the accompanying microphotographs. The epithelial masses become later altered in character and in a fourth-month human fetus the cells become granular and have the appearance of undergoing calcification. Unfortunately, I have as yet been unable to obtain sufficiently well preserved material to speak definitely on this point. It is interesting to notice in this connection that Professor W. B. Scott of Princeton has recently found three definitely calcified dentitions in *Nesodon.* Should it ultimately be shown that there is an attempt at calcification in the human prelacteal vestiges, it would furnish additional evidence that the primates have branched off very early from the common mammalian stem, as Wiedersheim has suggested.

There can be no question, I think, that there is a general tendency to the suppression of the earlier deciduous dentitions as evidenced by the *Rodentia,* some of the *Cynoidea,* etc. Taking these two sets of facts in conjunction it would appear to me that the simplest and most satisfactory interpretation of the condition in the marsupial jaws is that the three series represent: 1, A vestigial milk set, the prelacteal of Leche; 2, a functional persistent series; and 3, post permanent vestiges, the downgrowths of Kükenthal. A similar line of reasoning applies also to the condition found in the *Cetacea.* Such an interpretation would bring the dentition in these two classes into line with that of the *Eutheria* generally, and would clear away many of the difficulties arising from the present usually accepted views.

Shortly after putting forward this hypothesis in 1896 additional welcome evidence was advanced by Wilson and Hill who independently arrived at a similar conclusion, as a result of their investigations into the "Development and Succession of the Teeth in Perameles."

This position was subsequently attacked by the late M. F. Woodward and also by Deppendorf, mainly on the theoretical grounds that the rudimentary condition in which marsupials were born tend to the preservation of the earlier dentition. This objection to my mind is unconvincing, as the marsupial at birth is brought into conditions very different from those of the young reptile which has from the very first to forage for itself, whereas the marsupial is transferred at once to the mammary gland and is thus fed for a considerable time and so the necessity for the retention of the earlier dentition is absent and has led to its disappearance.

The next point to which I would draw attention is the anomaly in the tooth change in the posterior premolar region. This anomaly consists in the fact that, whereas in the anterior premolars these teeth are preceded by deciduous premolars of a similar pattern, in the case of the posterior premolar the milk predecessor is molariform in pattern. This condition, so well known in the dog, occurs in a considerable number of mammals belonging to other classes. It is known to occur in the *Marsupialia,* (in which this tooth is the only one to be replaced) in the *Carnivora, Insectivora* and *Rodentia.* Topinard has drawn attention to the molariform pattern of the deciduous posterior premolar in man; it seems therefore likely that we have here the same anomalous condition, and this point I am at present investigating.

I think we are dealing here with a case of apparent succession only, by which I mean that the deciduous posterior premolar is not the true morphologic predecessor of ppm^4, as in the case of other teeth. M. F. Woodward has stated that in the kangaroo the replacing tooth belongs to the same series as pm^4 and $pm,^4$ and the same I find holds true in the guinea-pig. In both these cases it is interesting to note that the successional tooth develops slightly in front of its predecessor and drops backward into its place, whereas in all other cases it develops behind the tooth which it replaces and therefore drops forward. A similar condition is to be met with in the *Insectivora* (Woodward) and in the dog (Tims). From a careful study of all the facts I have been led to the conclusion that the apparent deciduous posterior premolar is in reality the first of the molar series, the true morphologic dpm^4 being crowded out. The cause of this condition is I believe, to be found in the progressive shortening of jaw in relation to its breadth. Take the case of the marsupials, the time at which the single deciduous tooth is shed varies considerably; in some it is shed "in utero" as in *Dasyurus,* in *Thylacinus* before the animal leaves the mother's pouch, in others not until the animal is full grown as *Didelphys* and *Perameles,* while in *Myrmecobius* no tooth change is known.

The ratios of the palatal breadth to length works out as follows: *Dasyrus,* 1:1.6; *Thylacinus,* 1:2.03; *Didelphys,* 1:2.10; *Perameles,* 1:2.2; *Myrmecobius,* 1:3.2. It is worthy of note in this connection that *Myrmecobius* possesses at least five upper molars, a number in excess not merely of all other marsupials but of all other mammals. The same results are found in the diprotodont series.

I have elsewhere[1] shown that among the *Insectivora* parallel conditions are to be met with through such forms as *Centetes, Ericulus, Echinops* and *Solenodon*, in which the ratios of the palate breadth to length are as follows: *Centetes,* 1:2.76; *Ericulus,* 1:1.6; *Echinops,* 1:1.5; *Solenodon,* 1:1.1...*Centetes* has one more molar than any other insectivore, thus occupying a similar position to *Myrmecobius* among marsupials.

---

[1] Jour. Anat. and Phys., Vol. xxxvi, p. 321.

With regard to the rodents I have come to a like conclusion from a study of the tooth-genesis, viz.: that dpm4 is in reality the first tooth of the molar series. As already stated Topinard has drawn attention to the molariform character of the posterior deciduous premolar in man. Whether the tooth replacement is of the same nature I am at present unable to say definitely but I hope shortly to have cleared up this point.

Incidentally it may be mentioned that some animals, for example the guinea-pig, have tooth vestiges to the labial side of the true molars. If the latter belong to the successional dentition as Woodward, Lataste, Magitot and others affirm, and with much I entirely agree, then it follows that the usual definition of a molar as a tooth without a predecessor breaks down in theory.

The third point to which I would direct attention is the developmental history of the complex molar crown from the simple haplodont tooth of the *Reptilia.* In 1895 Professor Osborn delivered an address on "The History of the Cusps of the Human Molar Teeth" before the New York Institute of Stomatology. In that address Professor Osborn sketched the possible course of evolution from a simple cone through the tritubercular type of tooth. Through his many excellent papers on mammalian dentitions he has made the tritubercular theory so well known to all that it is quite unnecessary to restate it.

If this theory be examined critically, however, there seem to me to be unsurmountable difficulties, to some of which I would draw attention. The evidence in favor of this theory is mainly, if not entirely, paleontologic. While admitting the enormous value of such evidence, I do not think the embryologic can be overlooked. The researches of Täcker Röse, Woodward and others, have shown that in marsupials, ungulates, carnivores, rodents, and primates the paracone develops first and not the protocone as should be the case were this theory the true interpretation. Such uniformity in embryologic results cannot afford to be neglected. In some instances the metacone also precedes the protocone in appearing. It has been urged that this is a case of accelerated development. Such a suggestion is difficult to refute, and in the face of the accumulation of embryologic evidence, appears to be quite insufficient. Secondly, the rotation of the cusps necessary to evolve a tritubercular tooth from a triconodont is purely hypothetical, embryology furnishes no evidence of it, and paleontology offers, so far as I am aware, no transitional forms. Again, the absence of the protocone, as I have elsewhere[2] shown is the rule in the *Canidae,* even in such a primitive tooth as dpm^4, and the same is true of other animals. And lastly, there are the multituberculates, contemporaries with the trituberculates. Several other objections have been brought forward, but these alone seem to me to present great obstacles to the acceptance of this theory.

Neither does the multituberculate theory of Forsyth Major afford an adequate explanation for all mammals, though I believe it is applicable to the rodents and possibly to some other classes. The numerically reduced incisors together with the absence of canines and the presence of a diastema seems to place the multituberculates out of court as being the ancestors of animals with a full complement of teeth, such as carnivora and insectivora. Further it is I think generally admitted, that the pattern of the milk teeth is more primitive than that of their successors, and they are usually less tuberculate (Figs. 1 and 2).

The concresence of cusps representing originally separate teeth has been observed in certain fishes, in *Sphenodon* and in the chamelion but such examples are rare. Were such a theory an adequate explanation we might reasonably expect that many more examples would have been found when the enormous amount of embryologic research in the tooth genesis of mammals is taken into consideration. It is easy to be destructive, much less easy to be constructive. Neither of the above mentioned theories is to my mind satisfactory and I venture to suggest the outlines of another alternative hypothesis, based on the cingulum as a factor in the formation of new cusps (Fig. 3).

That the cingulum is a structure of extreme antiquity there can be no doubt. It is well marked in the anomodont reptiles. It is to be seen in the teeth of many fishes and is very evident in the teeth, specially those of the deciduous dentition, of mammals. Reconstructions of embryonic teeth show that the cingulum is relatively much larger than at a later period. Its function is probably that of affording protection to the gum when the haplodont teeth of the opposing jaws interlock. The effect of such an inter-action might give rise to small anterior and posterior cusps which increasing in size would give rise to the tri-conodont type of tooth such as is found in *Triconodon* and in *Amphilestes* as shown by Goodrich on full exposure of the teeth.

So far this hypothesis accords closely with that of the tritubercular theory. In passing from the reptiles to the mammals a different method of apposition of the jaws comes into play; in the former the jaws bite against one another whereas in the latter the lower jaw closes within the upper arcade. The apices of the lower cones would then fit between a cone of the upper series and the cingulum on its inner aspect causing a depression at that point and at the same time a separation inwards of the cingulum from its cone leading to a broadening of the upper tooth in the transverse diameter. The free edge of the upper internal cingulum would now act in a similar mechanical way on the lower teeth and cause them to broaden out transversely. The mechanical factors would thus operate first on the teeth of the upper jaw and this is in accord with the generally admitted fact that the pattern of the upper molars is the more primitive.

The formation of the smaller secondary cusps is due to the mechanical usage and presents but little difficulty when the problem of the initial stages of the genesis of the molar pattern is once solved.

The importance of the cingulum in cusp formation will I think be acceded by anyone after a careful examination of mammalian teeth generally. Many cusps will be found to be placed directly on it. The small cusps at the lateral margins of the milk incisors of the dog can be seen to be nothing more than the terminations of the internal cingulum which originally surrounded the base of the tooth but has now ceased to exist on the outer aspect, its protective function being

Illustrating Article by Dr. Tims.

no longer required. The cingulum is well marked in most human teeth, especially the bicuspids. For some reason, which I cannot explain, it occasionally happens that the outer portion of the cingulum persists and even gives rise to well marked cusps; such a condition is seen in *Otocyon* and in some of the *Insectivora* (Fig. 4).

The reason why the factors have not operated at the anterior part of the jaw and have allowed the incisors to retain a more primitive type, is to be found in the fact that the greater part of the force exerted by the muscles of mastication acts on the posterior teeth and indicated by the common use of the word "grinders." I take it that any theory put forward to account for the molar pattern should be expected to apply to both tritubercular and multitubercular teeth, and this I think is one great objection to the two hypotheses which go by those names. If the teeth of the multituberculata be examined it will be seen to consist of three transverse rows of cusps, though in some cases there are only two as in *Polymastodon tabensis* and in *Meniscoesus.* If we suppose an anteroposterior fusion of several teeth each consisting of a main central cone with external and internal cingulum cusps, there would result the more complex crown of the *Polymastodontidæ,* and at the same time would explain the great reduction in the total number of individual teeth (Fig. 5). The tendency to the reduction in the external portion of the cingulum in the mammalia is very general, and a similar condition affecting the multituberculate tooth would give the two transverse rows of cusps only as found in *P. tabensis* and *Meniscœsus.*

Space will not permit of a further application of this hypothesis to individual forms, it must suffice to say that from the multituberculate type it is not difficult to derive the pattern of molars found in the *Rodentia* and the *Proboscidea* (Fig. 6). I have been led to formulate this hypothesis from a study of the tooth-genesis in the *Carnivora, Rodentia,* primates and others, in every one of which the tooth arises in the first instance as a single cone with a marked cingulum.

The embryologic evidence of tooth-genesis in the rodents points to a multituberculate ancestry, thus agreeing with the paleontologic conclusions of Forsyth Major. The history, however, of the cusps differs from that of such forms as the carnivores and primates which leads in the direction of seeking for their primitive origin in some forms similar to, if not identical with, the fossil trituberculates (Figs. 7-11).

The inference from these conclusions is that we must look for at least a dual origin for the mammalia in mesozoic times. This may be regarded as an unorthodox conclusion, but I may be permitted to quote the words of the distinguished American paleontologist, Doctor J. L. Wortman, in his remarks at the conclusion of Professor Osborn's address above referred to. Dr. Wortman, in speaking of a polyphyletic origin of the mammalia, says that it is a hypothesis "not wholly unwarranted by the evidence already in our possession."

I fear that I have been able to give but the barest outline of this theory, but I hope that I have said sufficient to make clear the underlying idea, and I shall be amply rewarded if it but leads other workers to inquire into its validity. Any reasonable hypothesis has its value, if it should prove adequate it is so much gained, if the reverse it has cleared some of the mist from our eyes.

CAPITAL OPERATIONS FOR THE CURE OF TINNITUS AURIUM.[*]

W. SOHIER BRYANT, M.D.
NEW YORK.

I collected the material for this paper during my preparations for an excision of the auditory nerve in a case of grave tinnitus aurium, with suicidal tendencies. Several weeks were consumed in work on the cadaver and in designing special instruments. During this time my patient improved so much under enforced hygiene a capital operation no longer appeared justifiable.

Patient.—The patient was a psychopathic, neurasthenic man of 40, in fair physical condition and nutrition.

History.—He smoked to excess and had a questionable specific history. He complained of tinnitus on the left side, of inability to conduct his business, of disappointed ambitions, and of loss of sleep. Beginning in his fourth year, the left ear had continued to discharge until he was 26 years old. Some loss of hearing followed early, but a considerable part of the hearing was later lost suddenly. When he was 28 years old, the tinnitus, "a low-pitched hum in the head" when the right ear was stopped with the finger, was first noted. At the age of 37 he fell from a horse, bruised his head, and broke his leg. The tinnitus then became a high-pitched sizzling in the head or left ear, like the sound of a soda siphon. Previous to his present complaint he was strong and muscular and had great energy and endurance. At the time of examination he was weak and could not sleep or concentrate his mind on anything. He trembled and was exhausted by the effort to restrain himself and appear composed under the intolerable burden of the tinnitus.

He had consulted many specialists and others, including eight well-known practitioners of New York, because the tinnitus kept him awake. He said that at that time air did not enter the Eustachian tube. Though at first the tinnitus was only heard at night, it gradually became constant. He had received every sort of treatment. Some nasal polypi had been removed. Pilocarpin had been given to intoxication without any effect on the tinnitus. Last year a radical operation was performed. No change in the tinnitus resulted.

Examination.—When I first examined the patient he had a completely healed middle ear following the radical operation. The Eustachian tube was closed at the tympanic end with a dermatized cicatrix. No remnants of ossicles or tympanic membrane or other landmarks were visible.

He said that the pitch of the tinnitus would rise about one octave, and become louder before a storm, and then fall again. The tinnitus was in the head, and was loud enough to be heard above a brass band or a full orchestra. When it was imitated, the sound was much like that of a soda siphon, but no louder. The patient said that the pitch of the tinnitus varied gradually.

While he was under examination, he said that the pitch corresponded to F .512, S. V., then F .128, S. V., and again, ten minutes later, F .256, S. V., and again it dropped. In the left ear he heard nothing by air except F .1024, S. V. By bone conduction, all the normal scale could be heard. Bone conduction was equal for both ears when the right or good ear was stopped with the finger. The patient stated that the tinnitus was more annoying in a noisy than in a quiet place. When at its worst, he was forced to stop talking, and perspiration would stream off his face in his effort to endure it and to control his distress and exasperation. He had recently attempted suicide. At the time of the examination he weighed 124 pounds. At the age of 21 his maximum weight was 155 pounds.

Subsequent History.—After taking a vacation in the country for a few weeks, he became more composed and slept fairly well. He said that the tinnitus was perhaps a little less, but that there was no marked change. This improvement has lasted until now, for about one year.

---

[*] Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

chronic catarrhal conditions, with tinnitus. The treatment consisted of the radical mastoid operation and removal of the stapes. In the first case the result was a complete failure; in the second the operation was successful, and in the third case the tinnitus was reduced. Balance[6] published in 1900 an account of the removal of the semicircular canals for suppuration. The tinnitus ceased. In April, 1904, Wallace and Marriage[7] published a description of a section of the auditory nerve. The tinnitus was diminished, but death followed in three weeks. In July, 1904, Lake[8] published an account of the removal of the semicircular canals for vertigo. This operation had no influence on the coincident tinnitus. Shortly after this case he opened a cochlea, with temporary relief of the tinnitus. R. H. Parry[9] reported, in August, 1904, the division of the auditory nerve, resulting in improved tinnitus.

History.—In Parry's case, the patient was seized with sudden giddiness six years previously, and similar attacks recurred for two years. Then came a slight improvement. A year before the operation the attacks became more frequent again and very bad. There was severe tinnitus in the left ear and occasionally in the right. The patient had always been partially deaf in the left ear, which discharged until two years before operation. There was no alcoholic or syphilitic history.

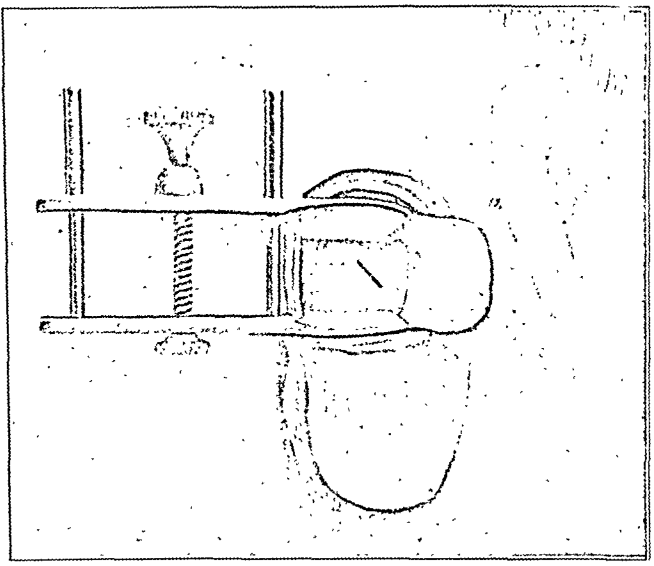

Figure 6.

Operation and Result.—The middle fossa was opened, and an osteoplastic flap extending from the center of the zygoma to the base of the mastoid process was made. The dura was elevated from the petrous bone to the semicircular canal. The tegmen was removed and some of the petrous pyramid. After the puncture of the dura to allow the escape of the cerebrospinal fluid, the soft parts were retracted. There was some bleeding. The removal of the roof of the auditory meatus exposed the seventh and eighth nerves. The facial nerve was torn by a spicule of bone. Giddiness and complete facial paralysis resulted, but an early improvement took place. Though lessened, the tinnitus persisted, and also the vertigo. The wound healed by first intention. A month later the dizziness and tinnitus were slightly better on the whole. A year later anastomosis of the facial and spinal accessory was done. As a result the tinnitus was considerably improved, but not the vertigo.

Figure 7.

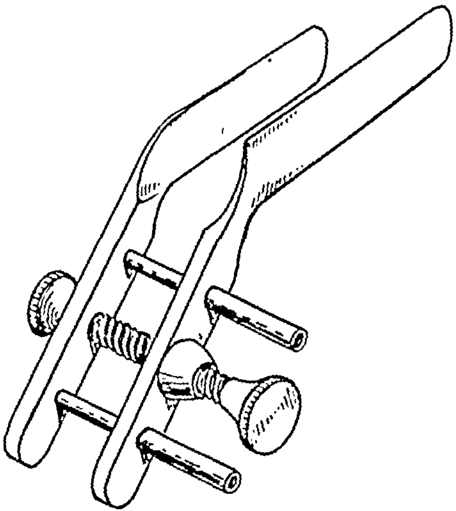

Figure 8.

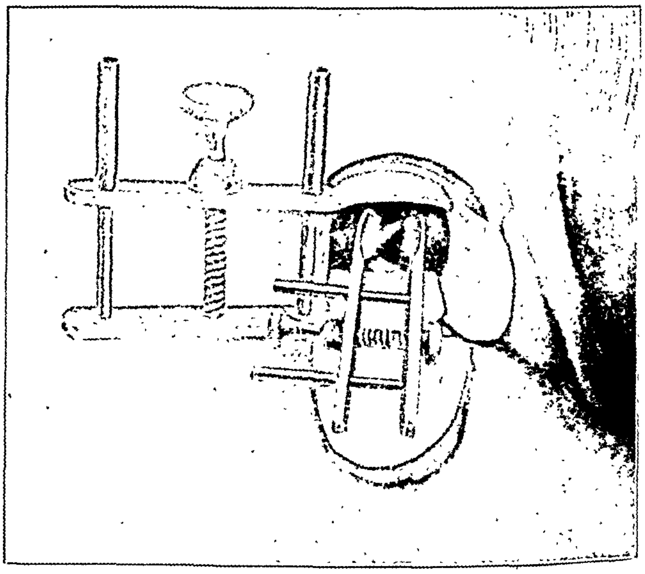

Figure 9.

In Krause's case,[4] the patient was a woman, 63 years old.

History.—In the right ear she had tinnitus, which prevented her from sleeping and rendered life unbearable. She also suffered from a "sclerotic process of the inner ear."

Operation and Result.—An osteoplastic flap was made of the right occipital region, with the base below. A similar dural flap was also made. The right cerebral hemisphere was displaced to the left with a spatula, and the auditory and facial nerves exposed. The bleeding of the cerebral veins was controlled by the gauge-tampon. The auditory nerve was cut. The operation lasted one hour and a half. On recovering from the anesthetic, the patient could not wink the right eye as well as the left. She said the tinnitus was not so bad as before (remarkable!), but complained of dizziness. She was very drowsy. The next day the tinnitus was noticeably less (!) and there was a slight paresis of the face. On the second day there was still less tinnitus, and the dizziness had entirely gone. The next day the patient was seized with a chill, and there was pneumonic sputa, and five days after the operation died from pneumonia.

Wallace and Marriage's Case.[7]—A mastoid operation had been performed on the patient. The middle ear was lined with healthy skin. The patient suffered from dizziness and tinnitus in the ear. The wall of the bony labyrinth was intact. A loud

extends downward to the lateral sinus about an inch and a half behind the anterior limb (Fig. 1). An osteoplastic flap may be made, but my experience shows that it is usually inexpedient, because of the great thickness of the bone and because of the impossibility of locating absolutely from the outside the position of the lateral sinus. The uncovered bone (Fig. 2) is perforated by my front-bent gouge (Fig. 3), and the opening enlarged with a heavy rongeur and carried well forward as far as the superior angle of the petrous pyramid and downward to the lateral sinus. The dura mater is cut with a "U" flap opening forward; the cerebrum is then carefully lifted with my spatula (Fig. 4) and the anterior surface of the petrous bone is explored for the eminence of the superior semicircular canal, which is the landmark for the route to the auditory nerve.

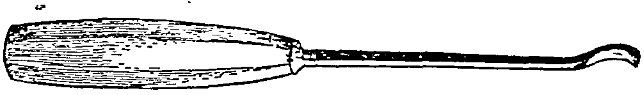

Figure 3.

If the cerebral veins are not found lying across the field of operation, my cerebral speculum (Fig. 5) is inserted to hold the cerebrum up off the anterior portion of the tentorium (Fig. 6). If the cerebral veins are in the way, they are first pinched off. With a probe the edge of the petrous bone is located, and with a bistoury a longitudinal cut is made in the tentorium parallel to the edge of the petrous bone, but well behind it, to avoid the superior petrosal sinus.

Veins generally can be distinctly seen running parallel with the edge of the petrous bone and the incision is made posterior to them. The cut is about half an inch long and lies behind the eminence of the superior semicircular canal. With my cerebellar spatula (Fig. 7), the posterior flap of the cerebellar incision is drawn backward. To see if the cut is sufficiently long, the spatula is inserted from one-half to three-fourths of an inch, and the cerebellum slowly pushed backward to disclose the brilliant white auditory nerve lying at the bottom of the wound directly in line with the eminence of the superior semicircular canal. My cerebellar speculum is then inserted (Fig. 8). The nerve is easily recognized on account of its position and its glistening snow-white appearance (Fig. 9). It lies between 4 and 5 cm. from the anterior edge of the wound and nearer the opening of the wound than the facial nerve, which lies farther inward and anterior to the auditory nerve.

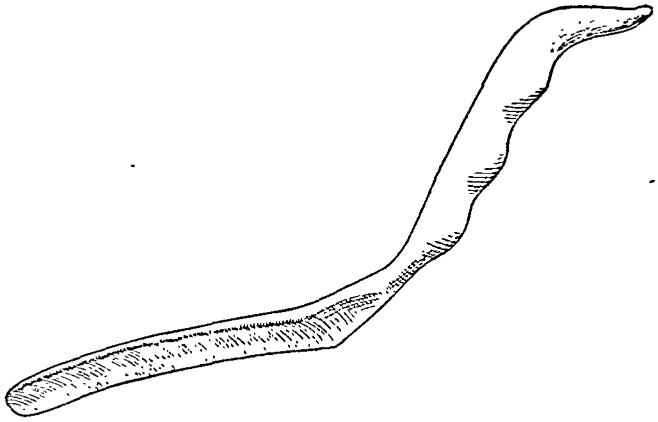

Figure 4.

The auditory nerve is grasped by small [illegible] forceps. Care must be taken to avoid [illegible] the facial nerve. Then the auditory nerve is pulled backward and outward from the internal auditory meatus, and if the proximal part of the nerve is not torn by this time the nerve is pulled outward and forward: the structure of the nerve is so soft and friable that this was found the easiest means of removing it. Next the facial nerve must be inspected, and if any shreds of the auditory nerve are seen lying on it these are to be removed in the same way as the trunk. In this operation very little displacement of the cerebrum is required and scarcely any of the cerebellum.

The chief difficulty of the operation will be due to the venous hemorrhage from the cut in the tentorium, but with care in avoiding the veins which are readily seen on the upper surface the hemorrhage need not be very great. The flow of the cerebrospinal fluid will be considerable and very annoying and will require frequent mopping even in the cadaver. The wound can be kept clean by gauze packing. When the wound is closed, a small drain running from the stump of the auditory nerve through the external angle of the tentorial incision, the anterior inferior end of the dura mater incision and the anterior inferior end of the skin flap should be left. This drain is intended to facilitate the flow of cerebrospinal fluid. The tentorium need not be sutured. Its rigidity and elastic texture bring it back in place. The dura mater, the periosteum and the skin flap are sutured, leaving only space enough for the drain.

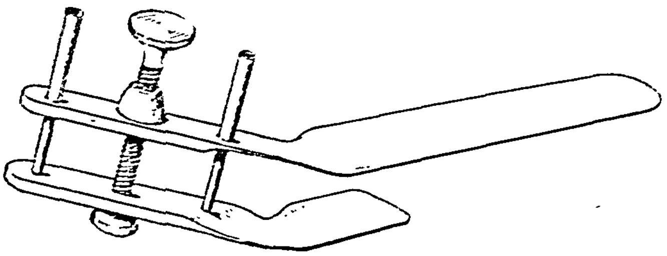

Figure 5.

PROGNOSIS.

The prognosis in regard to the cure of the tinnitus in these cases depends largely on the care with which the diagnosis is made before the operation. Of course, the causes of the cerebral tinnitus, if it exists, will not be much affected by the removal of the auditory nerve; but when the cause of the tinnitus can be located in the middle or inner ear or in the peripheral end of the auditory nerve, cure can be expected.

SUMMARY OF REPORTED CASES.

In 1884 J. Orne Green [illegible] removed the cochlea for grave tinnitus. [illegible] followed the operations, but the tinnitus continued. [illegible] the carotid. The tinnitus [illegible] were cerebral complications [illegible] ligated the carotid. [illegible]

[illegible]

Similar cases are met with now and again. Fortunately the number is not great. They usually end in suicide or insanity. In the psychopathic, a slight tinnitus leads to hallucinations of hearing and finally to insanity. In cases of grave tinnitus, any means of alleviation, no matter how severe or how great the risk, are justifiable. The torture which these people suffer can but be compared to the refinments of cruelty employed by the doges of Venice, when, for example, water was allowed to fall slowly, drop by drop, on the heads of the unfortunate offenders until they were bereft of reason. In a similar manner, the victims of these painless sounds become crazed, and attempt suicide for relief, or finally become demented.

On a few occasions the aid of major surgery has been sought to furnish relief for the unfortunate sufferers whom the intolerable burden of grave tinnitus had driven to desperation. The suggestions in this paper will be valuable if they add anything to the help which the medical profession has been able to give these sufferers in the past.

The work previously done in this field does not indicate clearly the operation to be followed in such cases, nor does it give any encouragement of good results. It does show, however, that it is most necessary to make an accurate diagnosis before operating and that an operation should be resorted to only in those cases in which the grave tinnitus is not clearly of central origin. It also shows that better technic is necessary.

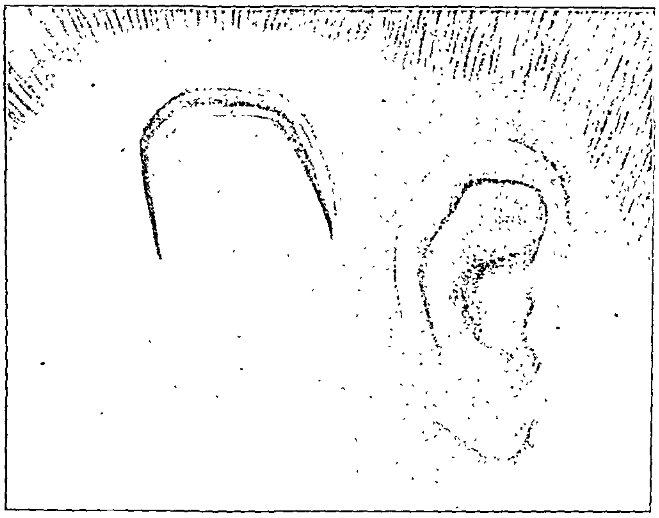

Figure 1.

INDICATIONS FOR OPERATION.

The indications for operating in grave tinnitus are akin to those found in trifacial neuralgia. Experience has here shown that a nerve trunk may be destroyed, cutting off all perceptions of undesirable centripetal impulses. The same must be true of the auditory nerve when the disagreeable sensations are those of sound. With the eighth pair, as well as with the fifth pair of nerves, the best results must be achieved by attacking the intracranial roots of the nerves. Ligature of the carotid is, at best, only a palliative measure. Intralabyrinthine destruction of the auditory nerve has extremely difficult technic and frequently has not been complete. There remains, therefore, nothing but intradural section of this nerve.

On account of the severity of the operation, other means should be tried and found unavailing before this operation is recommended to the patient. Suppuration should also be stopped before this operation is admissible. The source of the tinnitus must be located in or about the labyrinth. A central cause for the tinnitus would remain as effective after as before the operation. The selection of cases of grave tinnitus suitable for operation is very important. Many of the failures in the past can be attributed to mistakes in this particular. To offer any encouragement for operating, the source of the tinnitus must be on the distal side of the point of nerve section. The most promising cases for nerve section show marked loss in air conduction with preservation of bone conduction. Tinnitus, with definite cochlear lesions, low-pitched tinnitus, and tinnitus of varying character and pitch, offer good operating risks.

Tinnitus of high pitch, musical tinnitus or voices and complete deafness in both air and bone conduction offer contraindications for the operation. In a case in which deafness is present by both air and bone conduction, it is probable that the tinnitus originates in some part of the auditory nerve which is still functionating and that this lies more proximally than the cochlea. In cases in which there is good bone conduction hearing with the tinnitus, it is reasonable to suppose that the cause lies peripherally to the cochlea.

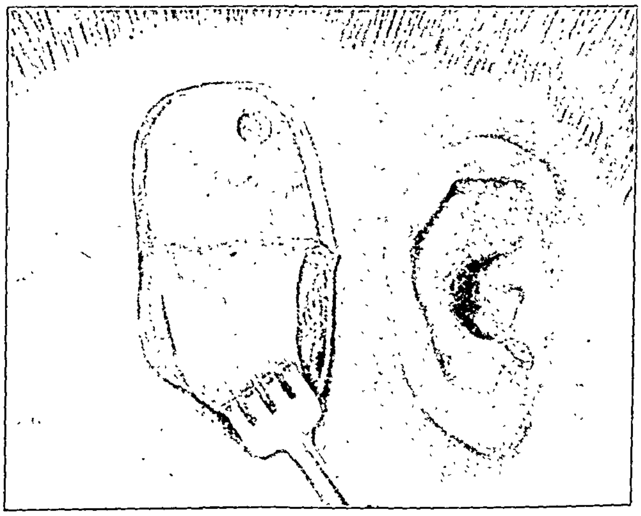

Figure 2.

Following a method of procedure suggested by my friend, Dr. Carleton Flynt, I performed 65 auditory neurectomies on the cadaver, besides those I did according to the methods described by others.

I acquired considerable efficiency, and by the aid of some instruments specially designed for the purpose I found no difficulty in removing the intra-arachnoid portion of the auditory nerve without any injury to the facial nerve. In most cases I was able to do this without interference with the cerebral veins which are the only possible source of annoying hemorrhage if the technic recommended is carefully followed.

TECHNIC.

Dr. Carleton Flynt suggested the most direct route by which the intradural portion of the auditory nerve may be reached with the least destruction of tissue and compression of the brain, especially of the cerebellum. This route goes through the middle fossa and enters the posterior fossa through the tentorium cerebelli. Inverted "U" skin and periosteal flaps are cut with their anterior limb behind the posterior edge of the mastoid process and extending about an inch and a half upward from the center of the lateral sinus. The posterior limb extends downward to the lateral sinus about an inch and a half behind the anterior limb (Fig. 1). An osteoplastic flap may be made, but my experience shows that it is usually inexpedient, because of the great thickness of the bone and because of the impossibility of locating absolutely from the outside the position of the lateral sinus. The uncovered bone (Fig. 2) is perforated by my front-bent gouge (Fig. 3), and the opening enlarged with a heavy rongeur and carried well forward as far as the superior angle of the petrous pyramid and downward to the lateral sinus. The dura mater is cut with a "U" flap opening forward; the cerebrum is then carefully lifted with my spatula (Fig. 4) and the anterior surface of the petrous bone is explored for the eminence of the superior semicircular canal, which is the landmark for the route to the auditory nerve.

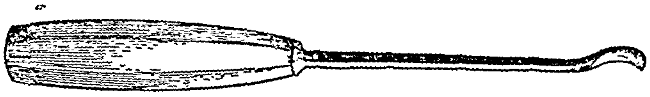

Figure 3.

If the cerebral veins are not found lying across the field of operation, my cerebral speculum (Fig. 5) is inserted to hold the cerebrum up off the anterior portion of the tentorium (Fig. 6). If the cerebral veins are in the way, they are first pinched off. With a probe the edge of the petrous bone is located, and with a bistoury a longitudinal cut is made in the tentorium parallel to the edge of the petrous bone, but well behind it, to avoid the superior petrosal sinus.

Veins generally can be distinctly seen running parallel with the edge of the petrous bone and the incision is made posterior to them. The cut is about half an inch long and lies behind the eminence of the superior semicircular canal. With my cerebellar spatula (Fig. 7), the posterior flap of the cerebellar incision is drawn backward. To see if the cut is sufficiently long, the spatula is inserted from one-half to three-fourths of an inch, and the cerebellum slowly pushed backward to disclose the brilliant white auditory nerve lying at the bottom of the wound directly in line with the eminences of the superior semicircular canal. My cerebellar speculum is then inserted (Fig. 8). The nerve is easily recognized on account of its position and its glistening snow-white appearance (Fig. 9). It lies between 4 and 5 cm. from the anterior edge of the wound and nearer the opening of the wound than the facial nerve, which lies farther inward and anterior to the auditory nerve.

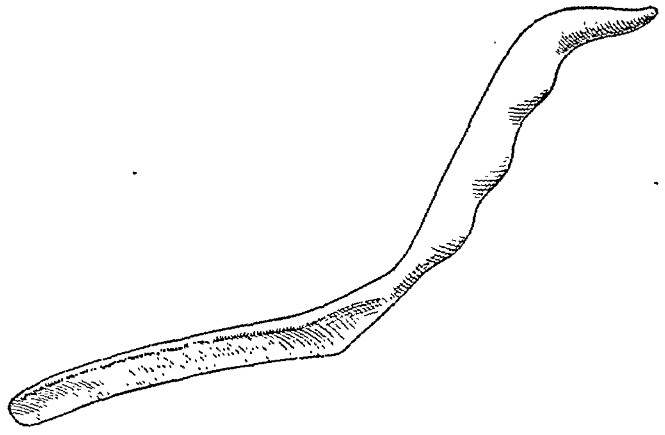

Figure 4.

The auditory nerve is grasped by small lock forceps. Care must be taken to avoid pinching the facial nerve. Then the auditory nerve is pulled backward and outward from the internal auditory meatus, and if the proximal part of the nerve is not torn by this time the nerve is pulled outward and forward; the structure of the nerve is so soft and friable that this was found the easiest means of removing it. Next the facial nerve must be inspected, and if any shreds of the auditory nerve are seen lying on it these are to be removed in the same way as the trunk. In this operation very little displacement of the cerebrum is required and scarcely any of the cerebellum.

The chief difficulty of the operation will be due to the venous hemorrhage from the cut in the tentorium, but with care in avoiding the veins which are readily seen on the upper surface the hemorrhage need not be very great. The flow of the cerebrospinal fluid will be considerable and very annoying and will require frequent mopping even in the cadaver. The wound can be kept clean by gauze packing. When the wound is closed, a small drain running from the stump of the auditory nerve through the external angle of the tentorial incision, the anterior inferior end of the dura mater incision and the anterior inferior end of the skin flap should be left. This drain is intended to facilitate the flow of cerebrospinal fluid. The tentorium need not be sutured. Its rigidity and elastic texture bring it back in place. The dura mater, the periosteum and the skin flap are sutured, leaving only space enough for the drain.

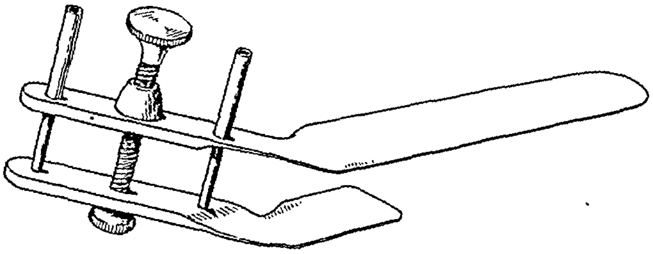

Figure 5.

PROGNOSIS.

The prognosis in regard to the cure of the tinnitus in these cases depends largely on the care with which the diagnosis is made before the operation. Of course, the causes of the cerebral tinnitus, if it exists, will not be much affected by the removal of the auditory nerve; but when the cause of the tinnitus can be located in the middle or inner ear or in the peripheral end of the auditory nerve, cure can be expected.

SUMMARY OF REPORTED CASES.

In 1884 J. Orne Green (unpublished) curetted the cochlea for grave tinnitus. Recovery followed the operations, but the tinnitus continued. Linsmayer[1] ligated the carotid. The tinnitus ceased for a short time. Severe cerebral complications resulted. Grunert[2] also ligated the carotid. The tinnitus reappeared in four months. In 1895 Meyerson[3] reported a ligature of the carotid. In four hours the tinnitus returned. Krause of Berlin[4] published, in 1903, the report of a case of section of the auditory nerve done some years previously. There was recovery from the operation and a lessening of the tinnitus. Death resulted from pneumonia. In 1900 Milligan[5] published an account of three cases of chronic catarrhal conditions, with tinnitus. The treatment consisted of the radical mastoid operation and removal of the stapes. In the first case the result was a complete failure; in the second the operation was successful, and in the third case the tinnitus was reduced. Balance[6] published in 1900 an account of the removal of the semicircular canals for suppuration. The tinnitus ceased. In April, 1904, Wallace and Marriage[7] published a description of a section of the auditory nerve. The tinnitus was diminished, but death followed in three weeks. In July, 1904, Lake[8] published an account of the removal of the semicircular canals for vertigo. This operation had no influence on the coincident tinnitus. Shortly after this case he opened a cochlea, with temporary relief of the tinnitus. R. H. Parry[9] reported, in August, 1904, the division of the auditory nerve, resulting in improved tinnitus.

[5] W. Milligan: Trans. of the Otol. Soc. of the United Kingdo 1900, p. 50.

History.—In Parry's case, the patient was seized with sudden giddiness six years previously, and similar attacks recurred for two years. Then came a slight improvement. A year before the operation the attacks became more frequent again and very bad. There was severe tinnitus in the left ear and occasionally in the right. The patient had always been partially deaf in the left ear, which discharged until two years before operation. There was no alcoholic or syphilitic history.

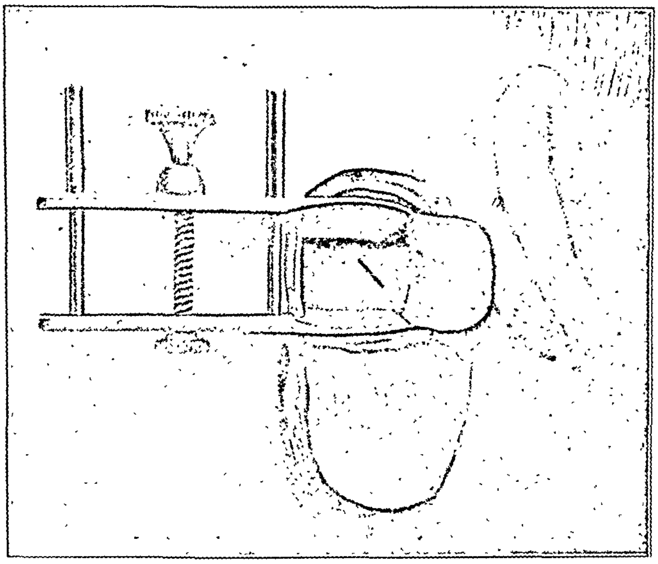

Figure 6.

Operation and Result.—The middle fossa was opened, and an osteoplastic flap extending from the center of the zygoma to the base of the mastoid process was made. The dura was elevated from the petrous bone to the semicircular canal. The tegmen was removed and some of the petrous pyramid. After the puncture of the dura to allow the escape of the cerebrospinal fluid, the soft parts were retracted. There was some bleeding. The removal of the roof of the auditory meatus exposed the seventh and eighth nerves. The facial nerve was torn by a spicule of bone. Giddiness and complete facial paralysis resulted, but an early improvement took place. Though lessened, the tinnitus persisted, and also the vertigo. The wound healed by first intention. A month later the dizziness and tinnitus were slightly better on the whole. A year later anastomosis of the facial and spinal accessory was done. As a result the tinnitus was considerably improved, but not the vertigo.

Figure 7.

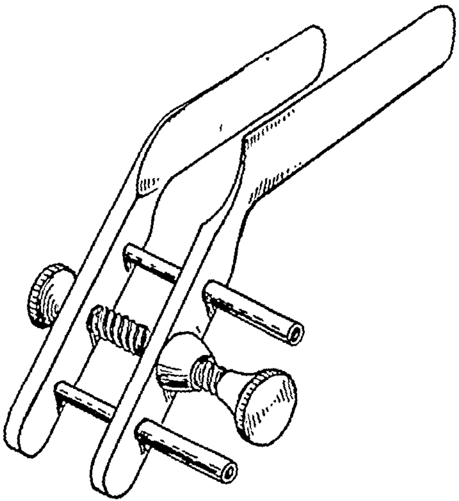

Figure 8.

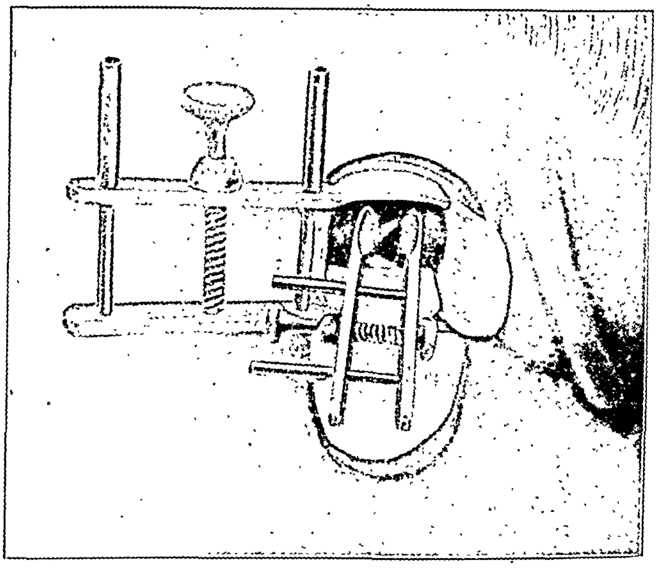

Figure 9.

In Krause's case,[4] the patient was a woman, 63 years old.

History.—In the right ear she had tinnitus, which prevented her from sleeping and rendered life unbearable. She also suffered from a "sclerotic process of the inner ear."

Operation and Result.—An osteoplastic flap was made of the right occipital region, with the base below. A similar dural flap was also made. The right cerebral hemisphere was displaced to the left with a spatula, and the auditory and facial nerves exposed. The bleeding of the cerebral veins was controlled by the gauge-tampon. The auditory nerve was cut. The operation lasted one hour and a half. On recovering from the anesthetic, the patient could not wink the right eye as well as the left. She said the tinnitus was not so bad as before (remarkable!), but complained of dizziness. She was very drowsy. The next day the tinnitus was noticeably less (!) and there was a slight paresis of the face. On the second day there was still less tinnitus, and the dizziness had entirely gone. The next day the patient was seized with a chill, and there was pneumonic sputa, and five days after the operation died from pneumonia.

Wallace and Marriage's Case.[7]—A mastoid operation had been performed on the patient. The middle ear was lined with healthy skin. The patient suffered from dizziness and tinnitus in the ear. The wall of the bony labyrinth was intact. A loud voice could be perceived, but not understood. A loud watch was heard only in contact with the mastoid process. The tuning fork placed on the forehead was heard only on the opposite side. When the fork was placed on the chin it was heard slightly in the affected ear, but sounded quite loud in the other ear. On the mastoid, the tuning fork was only faintly heard. On compression of the left carotid artery the tinnitus *ceased*. The tinnitus was like the sound of running water, and the sound of ringing bells was always present. It was most noticeable at night, especially when the patient lay on the affected ear. The tinnitus was so severe that sleep was rarely obtained without hypnotics, and was then disturbed and broken. The vertigo was of the type found in Ménière's disease. Drugs had been tried with absolutely no results, and the division of the auditory nerve appeared to be the only possible means of relief for the exhaustion of the patient.

[9] R. H. Parry: "A Case of Tinnitus and Vertigo Treated by Division of the Auditory Nerve," Jour. of Laryn., Rhin. and Otol., London, August, 1904, XIX, p. 402.

Operation.—The complete mastoid operation was performed. The lateral sinus was exposed and the posterior wall of the meatus removed. The dura mater over the temporal lobe was next exposed, and then that over the cerebellum behind the lateral sinus was laid bare for three-fourths of an inch. A part of the temporal bone extending from the lateral sinus forward and inward to the horizontal semicircular canal was then removed from the groove. This exposed the dura mater in front of the sinus for three-eighths of an inch. A flat retractor, one inch broad and bent at an angle, was inserted and the cerebellum compressed. With the aid of a forehead light, the auditory nerve was readily seen. A blunt hook was passed round the eighth nerve without injuring the facial nerve, and the auditory nerve was then divided by traction or scissors.

The bleeding from the lateral sinus was so great that the wound had to be plugged. Seven days later it was opened and the operation continued. On section of the dura mater much cerebrospinal fluid escaped. The lateral sinus persisting in the way, it was ligated and divided and the cerebellum pressed aside. On account of the flow of blood and of cerebrospinal fluid, a good view of the auditory nerve could not be obtained. Finally it was torn across by a blunt hook.

Result.—The operation appeared to be successful. The wound was closed and a small drain left at the lower edge. The next day there was facial paralysis. The tinnitus had greatly subsided, but was still obvious to the patient. She also had considerable dizziness and headache. The dressings were soaked with cerebrospinal fluid. On the second day, the flaps were bulged by a blood clot, some of which was let out. On the third day, there was some hernia and no attempt at healing. There was slight diplopia, with occasional vomiting. On the thirteenth day, the condition was the same. The diplopia cleared up. The wound was clean, but showed no signs of healing. The discharge of the cerebrospinal fluid continued and the headache was severe. There was no longer any complaint of tinnitus (!). The ocular fundi were normal. Though diminished, the tinnitus had probably remained present and never stopped. The patient died on the twenty-first day.

Autopsy.—No meningitis was found. The cerebrum was healthy throughout and the opposite cerebellar hemisphere was normal. The hemisphere operated on was somewhat soft, but showed no loss of substance. The cortex was blood stained and the vessels full of blood. The cochlea and the semicircular canals were normal. With the exception of a strand as thick as a fine piece of cotton, which lay next the facial nerve, the auditory nerve had been divided. The other organs were normal, save that there were old caseous foci in the lungs. Degeneration of the auditory nerve was found, also of the descending spinal root of the fifth nerve throughout its length in the pons and the medulla, which suggested that the efferent portion of the nerve had been damaged in its extramedullary course. A hemorrhagic softening surrounded a small vessel. This degeneration was confined to the fibers of the pons extending to the middle peduncle. The vestibular nerve was found to be completely degenerated.

DISCUSSION OF REPORTED CASES.

In the case reported by Green and Lake[8] the curetting of the cochlea is not worthy of extended consideration in this connection, because it is very difficult to destroy completely the cochlear nerve within the cochlea.

The accounts of Linsmayer,[1] Grunert[2] and Meyerson[3] show that ligation of the carotid has, at best, only a transitory effect on tinnitus. This method need not be discussed, because it does not directly destroy the perception of the tinnitus and because its effect is only indirect and very uncertain.

Lake's[8] report of the removal of the semicircular canal is irrelevant, because these canals are not supposed to be implicated in tinnitus. Balance's[6] case is excluded from the argument, because it was a case of active suppuration. The good results followed the cure of the suppuration.

The three cases of stapedectomy cited by Milligan[5] are not relevant, since they belong to the class of lesser middle-ear operations.

We now come to the consideration of the three sections of the auditory nerve which have been reported.

The technic followed by Krause[4] required a very extensive wound and extreme displacement of the cerebellum, which was probably sufficient to cause some degeneration. The description of the ear lesion given and of the tinnitus are not sufficient to make it clear where the tinnitus had its probable origin—whether in the middle ear, cochlea, auditory nerve or in the higher centers. After the operation the tinnitus was lessened, which is to be expected after any shock. The subsequent death of the patient indicates that she was probably not in a very observant frame of mind during the five days between the operation and the autopsy. It is worthy of remark that the tinnitus did not stop, nor is there any note of its change in character except that its intensity was diminished.

In the records given by Wallace and Marriage[7] the patient's hearing was very much diminished in the affected ear. Bone, as well as air conduction, was affected. This did not give a very good prognosis of improvement from the operation. The route selected for reaching the auditory nerve was the continuance inward of the common mastoid operation. This is laborious, because of the cracking of the bone, and slow because of the hemorrhage which follows. A clear view of the nerve required an operation in two sittings, disturbance of the lateral sinus and considerable displacement of the delicate cerebellum.

These cases are inconclusive, because in all some fibers of the auditory nerve were left intact. After the operation, the tinnitus was diminished in intensity—a change which follows every severe exhaustion. The fact that death followed the operation so quickly and the finding of the autopsy suggest that there was considerable degeneration and disturbance of the functions of the cerebellum.

In the case recorded by Parry[9] the ear conditions and symptoms of the patient were not sufficiently definite to form a prognosis for the operation. The route through the middle fossa and the petrous bone to the auditory nerve shows the danger of breaking the bone, as well as the danger of the unavoidable compression of the cerebrum. The patient recovered from the operation and was reported as slightly better on the whole. A year later the tinnitus was considerably better. The slow improvement in the tinnitus might suggest that the section of the auditory nerve was not a very positive factor in this change.

The cases cited by Krause, Wallace and Parry, taken together, do not throw much light on the subject. None of these cases shows proper care in locating the source of the tinnitus previous to the operation. In each of the cases, as far as we can learn from the description, the tinnitus might have been central. Moreover, all three operations are open to the criticism of unnecessary danger from injury to the cerebellum or to the facial nerve. The results of all the operations show that there was probably no direct connection between the irritation of the peripheral end of the auditory nerve and the tinnitus, because whatever improvement was noted came very gradually.

CONCLUSIONS.

The foregoing records justify the following conclusions:

1. Carefully selected cases of tinnitus, with the nerve stimulus located in the peripheral end of the auditory nerve, offer a good prognosis for cessation of the tinnitus after the section of the eighth nerve.
2. A technic which offers little inconvenience from hemorrhage, no danger from bony spicules, and a minimum of evil from compression of the cerebrum, or especially of the cerebellum, gives a good prognosis of recovery from the operation and in selected cases a cessation of the tinnitus.
3. If, after appropriate general and local treatment, grave tinnitus still exists, we are called on to recommend the section of the auditory nerve, provided the source of the tinnitus is believed to lie in the peripheral portion of the auditory nerve.
4. Section of the acoustic nerve will be as effective for the cure of aural vertigo as for peripheral tinnitus.

DISCUSSION.

Dr. John F. Barnhill, Indianapolis, asked if all the patients in whom parts of the auditory nerve were cut died from pneumonia, and if there was an explanation for two-thirds of the patients dying from this cause.

Dr. Bryant said in reply to the first question that one patient died of pneumonia after the operation, one died apparently of hemorrhage of the medulla, and the third was alive one year after the operation. In reply to the second question he said that he thinks it due to injury to the cerebellum, which seemed to be the primary cause.

PHLEBITIS FOLLOWING ABDOMINAL AND PELVIC OPERATIONS.*

A. H. CORDIER, M.D.
Professor of Principles and Practice of Surgery and Clinical Surgery, University Medical College; Chief Surgeon Kansas City, Mexico and Orient Railway.
KANSAS CITY, MO.

Following any surgical procedure there are many remote disasters occurring with sufficient frequency to keep the thoughtful surgeon on the lookout for these unforeseen complications for days and weeks, or until the patient's convalescence is at an end. The time of the occurrence of such complications varies from a few hours to several weeks after the operation. The change in character, from a postoperative hemorrhage to a phlebitis, begins from the second to the fifth week.

Inflammation of the saphenous or femoral vein following abdominal and pelvic operations, while rare, is met sufficiently often to be of much interest to surgeons engaged in this class of surgery. I have written to a number of the leading operators in this country asking for their personal experience with this condition in their postoperative cases, and I find by the replies that their experience is about the same as my own.

In discussing the causes of this condition one is confronted with the absence of postmortem and pathologic investigations, owing to the fact that very few of these patients die or have the diseased vein removed so that they can be examined by the pathologist. Anatomic peculiarities of the left common external iliac and femoral veins have been suggested as causes of the left side so frequently becoming the seat of a phlebitis. That the left saphenous vein is the vessel most frequently involved is true, but why this vein should be the one most often affected has not been thoroughly settled. Numerous theories have been advanced, but none of them, to me, appears tenable. The left common iliac frequently does not join at the usual place, but passes up on the left side of the aorta and enters the left renal vein. The left common iliac occasionally passes in front of the common iliac artery. In fact, when an anomaly exists in these veins, it is usually on the left side. The passage of the common iliac vein beneath the sigmoid has been mentioned as a causative factor because of the pressure on the returning blood from the left leg by an infected mass of feces in the bowel. A postoperative patient is not permitted to have an impacted sigmoid, as a rule. Malnutrition of the veins, the outcome of a venous stasis, is unquestionably a predisposing cause to a venous thrombosis, and a mild or severe infection at site of this thrombus is all that is necessary to inaugurate a secondary septic phlebitis.

One author (Favor) reports two cases of phlebitis of lower extremities resembling puerperal phlebitis, except that the patients did not have any fever, and thus, he says, the condition was non-infective. He considers such cases as due to the increase of "mineral matter in the blood, especially calcium salts, diminished oxidation, lessened elimination of urea, lessened alkalinity of blood and increased fibrin-forming material in the blood due to the puerperal state." His patients recovered within ten days. Constitutional causes usually act bilaterally, as was the case in these two patients.

The inguinal glands are among the most important glandular centers of the body. They are located in Scarpa's triangle and in close proximity to the superficial epigastric the superficial circumflex iliac, superficial external pudic arteries and their corresponding veins and the junction of the internal saphenous and femoral veins. These glands receive the cutaneous lymphatics of the abdominal walls below the umbilicus. Although these glands are in close proximity to the affected vein, they are very rarely enlarged during the attack.

The majority of the incisions for the removal of intraperitoneal pathology are made in the median line and usually slightly to the left, to avoid the wounding of the urachus. Admitting that an infection in this wound might lead to a phlebitis of left femoral, there yet remains, unexplained, why an incision over the gall bladder or appendix is equally as liable to produce the same complication in left leg.

Gerster, in an admirable article,[1] says: "It is significant that almost all of these mysterious cases of postoperative septicemia occur after 'interval' operations for appendicitis; that is, in those cases in which repeated attacks of a local sepsis have preceded and, presumably, have left behind deposits of an equivocal character." This statement was made in support of his position that in the so-called aseptic operations there exist, at the time of the operation, septic foci. This, I believe, is in part true, and, in the cases in which there existed no foci of infection at the time of the operation, the death of the distal end of tied-off tissues acted as a nucleus for the development of a mild type of local infection from the bacteria circulating in the blood at the junction of the dead and living structures. Phlebitis of these veins follows operations performed in other parts of the body than the abdomen, as the following case may incidentally illustrate. In the majority of the cases the left saphenous has been the vein involved. I operated on Mr. B. for gangrene of right lung. Two weeks later a phlebitis of left saphenous vein developed. He made a tardy recovery.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Septic Thrombosis of Portal Vein in Appendicitis, Med. Rec., June 27, 1903.

That the left femoral and saphenous veins are chosen fields for bacterial colonization no one will doubt, after analyzing the location of the phlebitis in a large series of cases (Fig. 1). I am firmly of the opinion that these germs reach these selected points through the blood, after traversing the heart, lungs and arteries, and thus reach the walls of the veins and that the thrombus, when one forms, is formed as a secondary process. If the walls of the vein received the infection from the venous blood, thrombi would form earlier in the process of the inflammation, and the disease would be of a more serious character insofar as permanent injury to the veins is concerned. Loss of muscular aid in pumping blood toward the heart has been mentioned as a cause, but this would apply equally to both legs.

Keen has suggested that "the passage of the left common iliac vein under the right common iliac artery and under the left internal, might lead to a retardation of the venous blood in left vein and thus act as a cause of venous thrombosis (Fig. 2). When we recognize that the thrombus, when one forms, is usually secondary to the phlebitis in this locality, this theory of pressure on vein loses much of its weight. If the disease of the vein proper is secondary to the thrombus formation, as some authorities claim, there must be some anatomic arrangement favorable to the development of a thrombus in the left femoral and internal saphenous that does not exist in other veins of the body. If this local condition is due alone to a general gouty dyscrasia or to pathogenic germs circulating in the blood, it would be as liable to occur in the right leg as in the left; in both, or in other, veins of the body.

I do not believe that the cause is to be found in the general circulation alone. The walls of the vein are primarily attacked, hence the agent producing the phlebitis must reach the vessel walls either through arteries, lymphatics or, if the venous circulation, there must exist in this left vein a want of resistance to bacterial invasion that is not found in the right leg. Isolated spots of infection of the affected vein are frequently noticed, those farthest away from the body appearing last in most instances. Because of this, multiple thrombi may form in the vessel.

Most of the French clinicians believe that the process is primarily an infection of the venous walls. Maurice Richardson believes that it is especially liable to follow operations in the pelvis of anemic patients and that the disease is aseptic in its origin and in its course. Schenck reports 48 cases occurring in Johns Hopkins Hospital, being about 1.5 per cent. of all abdominal operations. Of this number 40 per cent. were for removal of uterine fibroids and the great majority were seemingly aseptic cases. Noble says: "Many cases of phlebitis can not be explained on the ground of infection. Phlebitis occurs in about 1 per cent. of all cases." Dunning: "Phlebitis occurs more frequently from a suprapubic than from a vaginal hysterectomy." Richardson: "I probably see ten a year. Usually follows operations in deep pelvis, most commonly hysterectomy. After clean operation." Carstens says: "I always consider all such of aseptic origin, although it is funny that you have no sepsis whatever in the wound, or apparently anywhere else." Welch was able in his laboratory to demonstrate the presence of bacteria in over 70 per cent. of these cases following typhoid. He believes that the thrombosis is due to localized infection of the vein's wall. In the rare instances in which the disease begins in the right leg it almost invariably will attack the left also.

It was maintained for a long time that the infection in phlebitis was transported by the white corpuscles to a thrombus already formed. The infection of a femoral vein following an abdominal operation does not appear to be one of extension by continuity from the pelvic structures. A thrombus may form in a vein from compression, as from a tense fascia, or lymphatic glandular pressure, or inflammation of perivenous tissue. In these cases, owing to the inflammatory thickening, it is not always possible to diagnose a thrombus by palpation or otherwise. Weakened heart action in debilitated patients is mentioned as one of the causes of thrombus in vessels farthest removed from the heart (marasmic thrombus of Billroth). Slowness of blood current and collapsibility of veins predispose the vessels to thrombus formation, because the collapsed walls or inflamed walls easily come in contact and a thrombus is thus predisposed, because of the fibrin deposited on one wall adheres to the opposite side and thus the canal of the vessel is occluded.

In reviewing the cases I find that about 30 per cent. followed operations for the removal of the uterus for fibroids. In all hysterectomies (abdominal) many ligatures are used and much tissue is compressed and later becomes necrotic, a septic cavity (uterine) is opened and no drainage is put in. The conditions left in pelvis are favorable for the development of a mild type of infection (local and constitutional) at the site of tied-off tissues. This would naturally occur about ten days or two weeks later. In vaginal operations (rarely followed by a phlebitis) the same structures are constricted, but here there is good drainage and Nature is not compelled to take care of the infected necrotic tissues by absorption.

Keiffer of St. Louis reports a case of left saphenous inflammation following interval appendicitis operation. The patient left the hospital too early and returned to his home, but was found dead in his bed next morning —presumably from cerebral embolism. In one of my cholecystotomies the patient developed a left saphenous phlebitis on the seventh day. On the tenth day following the operation, or three days after phlebitis began, she died suddenly from a cerebral embolism.

Pulmonary embolism follows operations for uterine fibroma more frequently than it follows any other abdominal operation. This is true also of phlebitis of femoral and saphenous veins.

Miller[2] reports 8 cases of phlebitis following abdominal operations which resulted in either a pulmonary embolism or a pleurisy, or sudden death. For instance: Take two patients who are in identically the same general rundown condition. In one Nature is loaded down with the disposition of pedicle tissue, as in an abdominal hysterectomy, and mild infection; in the other, as in a vaginal hysterectomy, drainage relieves the patient of this added responsibility. In pyosalpinx and other suppurative processes in the pelvis an immunity has operations are open to the criticism of unnecessary danger from injury to the cerebellum or to the facial nerve. The results of all the operations show that there was probably no direct connection between the irritation of the peripheral end of the auditory nerve and the tinnitus, because whatever improvement was noted came very gradually.

---

[2] American Journal Obstetrics, April, 1905.

CONCLUSIONS.

The foregoing records justify the following conclusions:

1. Carefully selected cases of tinnitus, with the nerve stimulus located in the peripheral end of the auditory nerve, offer a good prognosis for cessation of the tinnitus after the section of the eighth nerve.
2. A technic which offers little inconvenience from hemorrhage, no danger from bony spicules, and a minimum of evil from compression of the cerebrum, or especially of the cerebellum, gives a good prognosis of recovery from the operation and in selected cases a cessation of the tinnitus.
3. If, after appropriate general and local treatment, grave tinnitus still exists, we are called on to recommend the section of the auditory nerve, provided the source of the tinnitus is believed to lie in the peripheral portion of the auditory nerve.
4. Section of the acoustic nerve will be as effective for the cure of aural vertigo as for peripheral tinnitus.

DISCUSSION.

Dr. John F. Barnhill, Indianapolis, asked if all the patients in whom parts of the auditory nerve were cut died from pneumonia, and if there was an explanation for two-thirds of the patients dying from this cause.

Dr. Bryant said in reply to the first question that one patient died of pneumonia after the operation, one died apparently of hemorrhage of the medulla, and the third was alive one year after the operation. In reply to the second question he said that he thinks it due to injury to the cerebellum, which seemed to be the primary cause.

PHLEBITIS FOLLOWING ABDOMINAL AND PELVIC OPERATIONS.*

A. H. CORDIER, M.D.
Professor of Principles and Practice of Surgery and Clinical Surgery, University Medical College; Chief Surgeon Kansas City, Mexico and Orient Railway.
KANSAS CITY, MO.

Following any surgical procedure there are many remote disasters occurring with sufficient frequency to keep the thoughtful surgeon on the lookout for these unforeseen complications for days and weeks, or until the patient's convalescence is at an end. The time of the occurrence of such complications varies from a few hours to several weeks after the operation. The change in character, from a postoperative hemorrhage to a phlebitis, begins from the second to the fifth week.

Inflammation of the saphenous or femoral vein following abdominal and pelvic operations, while rare, is met sufficiently often to be of much interest to surgeons engaged in this class of surgery. I have written to a number of the leading operators in this country asking for their personal experience with this condition in their postoperative cases, and I find by the replies that their experience is about the same as my own.

In discussing the causes of this condition one is confronted with the absence of postmortem and pathologic investigations, owing to the fact that very few of these patients die or have the diseased vein removed so that they can be examined by the pathologist. Anatomic peculiarities of the left common external iliac and femoral veins have been suggested as causes of the left side so frequently becoming the seat of a phlebitis. That the left saphenous vein is the vessel most frequently involved is true, but why this vein should be the one most often affected has not been thoroughly settled. Numerous theories have been advanced, but none of them, to me, appears tenable. The left common iliac frequently does not join at the usual place, but passes up on the left side of the aorta and enters the left renal vein. The left common iliac occasionally passes in front of the common iliac artery. In fact, when an anomaly exists in these veins, it is usually on the left side. The passage of the common iliac vein beneath the sigmoid has been mentioned as a causative factor because of the pressure on the returning blood from the left leg by an infected mass of feces in the bowel. A postoperative patient is not permitted to have an impacted sigmoid, as a rule. Malnutrition of the veins, the outcome of a venous stasis, is unquestionably a predisposing cause to a venous thrombosis, and a mild or severe infection at site of this thrombus is all that is necessary to inaugurate a secondary septic phlebitis.

One author (Favor) reports two cases of phlebitis of lower extremities resembling puerperal phlebitis, except that the patients did not have any fever, and thus, he says, the condition was non-infective. He considers such cases as due to the increase of "mineral matter in the blood, especially calcium salts, diminished oxidation, lessened elimination of urea, lessened alkalinity of blood and increased fibrin-forming material in the blood due to the puerperal state." His patients recovered within ten days. Constitutional causes usually act bilaterally, as was the case in these two patients.

The inguinal glands are among the most important glandular centers of the body. They are located in Scarpa's triangle and in close proximity to the superficial epigastric the superficial circumflex iliac, superficial external pudic arteries and their corresponding veins and the junction of the internal saphenous and femoral veins. These glands receive the cutaneous lymphatics of the abdominal walls below the umbilicus. Although these glands are in close proximity to the affected vein, they are very rarely enlarged during the attack.

The majority of the incisions for the removal of intraperitoneal pathology are made in the median line and usually slightly to the left, to avoid the wounding of the urachus. Admitting that an infection in this wound might lead to a phlebitis of left femoral, there yet remains, unexplained, why an incision over the gall bladder or appendix is equally as liable to produce the same complication in left leg.

Gerster, in an admirable article,[1] says: "It is significant that almost all of these mysterious cases of postoperative septicemia occur after 'interval' operations for appendicitis; that is, in those cases in which repeated attacks of a local sepsis have preceded and, presumably, have left behind deposits of an equivocal character." This statement was made in support of his position that in the so-called aseptic operations there exist, at the time of the operation, septic foci. This, I believe, is in part true, and, in the cases in which there existed no foci of infection at the time of the operation, the death of the distal end of tied-off tissues acted as a nucleus for the development of a mild type of local infection from the bacteria circulating in the blood at the junction of the dead and living structures. Phlebitis of these veins follows operations performed in other parts of the body than the abdomen, as the following case may incidentally illustrate. In the majority of the cases the left saphenous has been the vein involved. I operated on Mr. B. for gangrene of right lung. Two weeks later a phlebitis of left saphenous vein developed. He made a tardy recovery.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Septic Thrombosis of Portal Vein in Appendicitis, Med. Rec., June 27, 1903.

That the left femoral and saphenous veins are chosen fields for bacterial colonization no one will doubt, after analyzing the location of the phlebitis in a large series of cases (Fig. 1). I am firmly of the opinion that these germs reach these selected points through the blood, after traversing the heart, lungs and arteries, and thus reach the walls of the veins and that the thrombus, when one forms, is formed as a secondary process. If the walls of the vein received the infection from the venous blood, thrombi would form earlier in the process of the inflammation, and the disease would be of a more serious character insofar as permanent injury to the veins is concerned. Loss of muscular aid in pumping blood toward the heart has been mentioned as a cause, but this would apply equally to both legs.

Keen has suggested that "the passage of the left common iliac vein under the right common iliac artery and under the left internal, might lead to a retardation of the venous blood in left vein and thus act as a cause of venous thrombosis (Fig. 2). When we recognize that the thrombus, when one forms, is usually secondary to the phlebitis in this locality, this theory of pressure on vein loses much of its weight. If the disease of the vein proper is secondary to the thrombus formation, as some authorities claim, there must be some anatomic arrangement favorable to the development of a thrombus in the left femoral and internal saphenous that does not exist in other veins of the body. If this local condition is due alone to a general gouty dyscrasia or to pathogenic germs circulating in the blood, it would be as liable to occur in the right leg as in the left; in both, or in other, veins of the body.

I do not believe that the cause is to be found in the general circulation alone. The walls of the vein are primarily attacked, hence the agent producing the phlebitis must reach the vessel walls either through arteries, lymphatics or, if the venous circulation, there must exist in this left vein a want of resistance to bacterial invasion that is not found in the right leg. Isolated spots of infection of the affected vein are frequently noticed, those farthest away from the body appearing last in most instances. Because of this, multiple thrombi may form in the vessel.

Most of the French clinicians believe that the process is primarily an infection of the venous walls. Maurice Richardson believes that it is especially liable to follow operations in the pelvis of anemic patients and that the disease is aseptic in its origin and in its course. Schenck reports 48 cases occurring in Johns Hopkins Hospital, being about 1.5 per cent. of all abdominal operations. Of this number 40 per cent. were for removal of uterine fibroids and the great majority were seemingly aseptic cases. Noble says: "Many cases of phlebitis can not be explained on the ground of infection. Phlebitis occurs in about 1 per cent. of all cases." Dunning: "Phlebitis occurs more frequently from a suprapubic than from a vaginal hysterectomy." Richardson: "I probably see ten a year. Usually follows operations in deep pelvis, most commonly hysterectomy. After clean operation." Carstens says: "I always consider all such of aseptic origin, although it is funny that you have no sepsis whatever in the wound, or apparently anywhere else." Welch was able in his laboratory to demonstrate the presence of bacteria in over 70 per cent. of these cases following typhoid. He believes that the thrombosis is due to localized infection of the vein's wall. In the rare instances in which the disease begins in the right leg it almost invariably will attack the left also.

It was maintained for a long time that the infection in phlebitis was transported by the white corpuscles to a thrombus already formed. The infection of a femoral vein following an abdominal operation does not appear to be one of extension by continuity from the pelvic structures. A thrombus may form in a vein from compression, as from a tense fascia, or lymphatic glandular pressure, or inflammation of perivenous tissue. In these cases, owing to the inflammatory thickening, it is not always possible to diagnose a thrombus by palpation or otherwise. Weakened heart action in debilitated patients is mentioned as one of the causes of thrombus in vessels farthest removed from the heart (marasmic thrombus of Billroth). Slowness of blood current and collapsibility of veins predispose the vessels to thrombus formation, because the collapsed walls or inflamed walls easily come in contact and a thrombus is thus predisposed, because of the fibrin deposited on one wall adheres to the opposite side and thus the canal of the vessel is occluded.

In reviewing the cases I find that about 30 per cent. followed operations for the removal of the uterus for fibroids. In all hysterectomies (abdominal) many ligatures are used and much tissue is compressed and later becomes necrotic, a septic cavity (uterine) is opened and no drainage is put in. The conditions left in pelvis are favorable for the development of a mild type of infection (local and constitutional) at the site of tied-off tissues. This would naturally occur about ten days or two weeks later. In vaginal operations (rarely followed by a phlebitis) the same structures are constricted, but here there is good drainage and Nature is not compelled to take care of the infected necrotic tissues by absorption.

Keiffer of St. Louis reports a case of left saphenous inflammation following interval appendicitis operation. The patient left the hospital too early and returned to his home, but was found dead in his bed next morning —presumably from cerebral embolism. In one of my cholecystotomies the patient developed a left saphenous phlebitis on the seventh day. On the tenth day following the operation, or three days after phlebitis began, she died suddenly from a cerebral embolism.

Pulmonary embolism follows operations for uterine fibroma more frequently than it follows any other abdominal operation. This is true also of phlebitis of femoral and saphenous veins.

Miller[2] reports 8 cases of phlebitis following abdominal operations which resulted in either a pulmonary embolism or a pleurisy, or sudden death. For instance: Take two patients who are in identically the same general rundown condition. In one Nature is loaded down with the disposition of pedicle tissue, as in an abdominal hysterectomy, and mild infection; in the other, as in a vaginal hysterectomy, drainage relieves the patient of this added responsibility. In pyosalpinx and other suppurative processes in the pelvis an immunity has been established in the patient, so that at the time of the operation she is not likely to become generally septic, many of these operations being followed by drainage.

---

[2] American Journal Obstetrics, April, 1905.

In most of my cases the first symptoms of this complication have developed in the second or third week following the operation, regardless of the character of the case operated on. If there has been any difference at all, the phlebitis has followed operations for the removal of seemingly aseptic growths, as uterine fibroids, cirrhotic ovaries and interval operations for appendicitis. It would look as though the infection was either introduced through a defective aseptic technic or was due to the absorption of the pedicle at the site of the operation. To the latter theory I am disposed to lean, but this does not explain why the left vein should be most frequently involved, even though the operation was performed on the right side, as is the case in appendicitis, common-duct operations and right oöphorectomy. The usual onset of this condition is marked by a gradually increasing pain along some portion of the long saphenous vein, usually the left and most frequently just below the saphenous opening in the fascia lata. This pain may extend along the whole course of the vein and, as a rule, does follow the vessel below the knee. An elevation of temperature of from 2 to 3 degrees is noticed and a proportionately increased pulse rate is also observed. The pain in limb is increased by moving the limb or by permitting it to remain in a dependent position, and is partially relieved by elevating the leg and thigh. On examining, in many cases, there will be noticed a redness along the course of the inflamed vein or veins. If seen early, no perceptible swelling of the limb will be noticed, but within a few days, if the case is a severe one, the whole limb will be swollen, but more particularly the calf of the leg. This swelling is uniform and free from discolorations or redness, in fact, the surface is blanched. Pressure along the course of the vein elicits tenderness, and in the calf of the leg the tenderness is found all over the posterior surface. The vein is hardened and rolls under the fingers like a tendon in many cases. Pressure, if continued for several minutes, may produce pitting, but not so well marked as in the dropsical affections. Except along the course of the superficial portion of the vein, which may feel unnaturally warm, there is a deathlike temperature of the surface to the examining hand. This condition must not be confounded with a postoperative neuritis of the internal and middle cutaneous or the musculo-cutaneous nerve on outer side of leg and dorsal surface of foot, as illustrated by the following case:

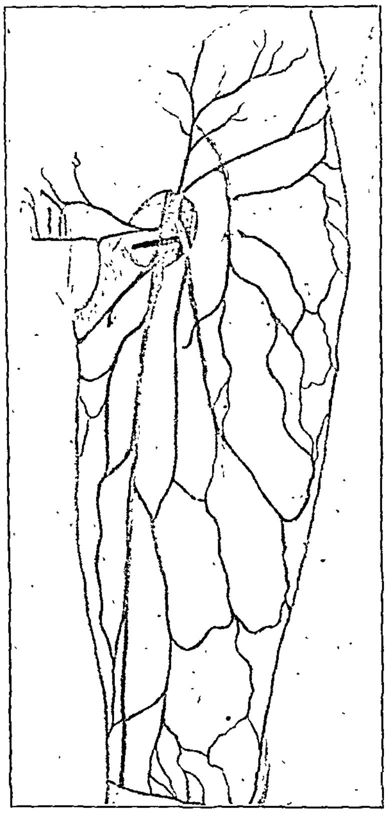

Fig. 1.—The left saphenous at its entrance into the femoral is most frequently the point first affected.

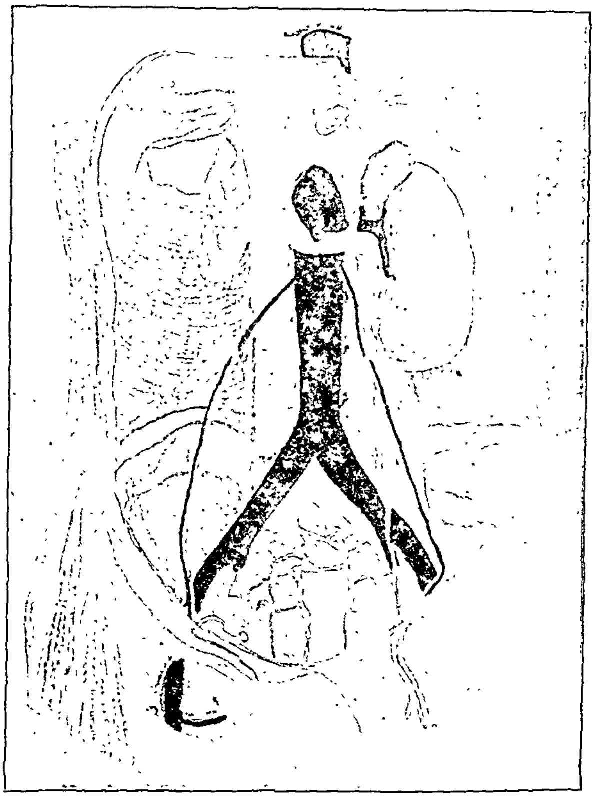

Fig. 2.—Keen says: "The passage of the left common iliac vein under the right common iliac artery might lead to a retardation of blood in vein, and thus favor a left saphenous or femoral thrombosis."

Case 1.—Mrs. B., aged 36, nullipara, complained of some pain near exit of right great sciatic nerve, at its exit from pelvis. Examination showed a small ovarian cyst. This was removed by abdominal route. Her progress was smooth for the first three weeks; then she developed the following symptoms and condition: a rapidly spreading pain over areas of distribution on internal, middle and musculo-cutaneous nerves, tenderness over limited areas, firm pressure seemingly better borne than a gentle touch. Leg swollen, but not uniformly, does not pit on pressure, as no edema was found. Position does not appear to increase or diminish the swelling. The leg to the touch feels natural in as far as concerns the temperature. Cold air increases the pain. No elevation of temperature or increase in pulse rate. Six months later I examined this woman and found her in perfect health.

Case 2.—Mrs. Z., aged 33; nullipara. No history of sepsis in pelvis or abdomen. Uterine fibroma. Hysterectomy. Incision in abdomen healed aseptically. On the eleventh day after operation she first complained of pain near the junction of saphenous and femoral veins. This pain soon extended to the calf of the leg. Tenderness developed along the course of saphenous to inner side of knee, later into calf; redness developed along course of upper portion of the vein. At end of four days a cord-like hardness could be made out along course of the vein. Her appetite was much impaired, tongue coated, pulse 96, temperature 100 to 101. At the end of a week the thigh and the leg were much swollen, with no general redness. Pain and swelling increased by dependence of leg. The acute febrile symptoms subsided at the end of ten days, but left the leg tender and swollen. At the end of three weeks from beginning of phlebitis she left the hospital. The leg continued tender for several months. Two years later I found the left leg one and one-half inches larger than the right. No visible enlargements or tortuosity of veins.

Case 3.—Mr. E.: chronic appendicitis; interval operation; postoperative left saphenous phlebitis. This young man, aged 21, had suffered from mild recurring attacks of appendicitis for three years. Operation in interval of attacks. Usual postoperative history, fourteenth day, when he noticed a soreness in left leg along course of internal saphenous vein, extending to calf of same leg. Temperature 101, pulse 100. Tenderness along vein, slight swelling of leg. Symptoms subsided at end of two weeks and he left about well, save a slight stiffness about leg and thigh. A year later I found him entirely well.

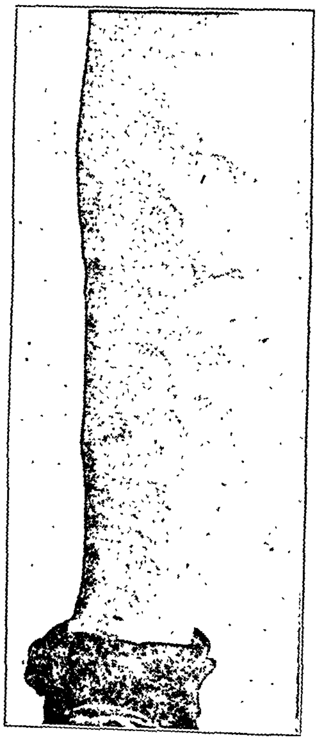

Fig. 3.—Varicosity of veins of left leg from a descending phlebitis of saphenous vein following an "interval" operation for appendicitis.

Byron Robinson[3] reports a sudden death following the flexing of the thigh on the abdomen in a patient on whom seventeen days previously he had performed a vaginal hysterectomy. The autopsy showed a phlebitis of left ovarian vein, and an occlusion of pulmonary artery with elongated spindle-shaped blood clots.

Dr. Lucy Waite reports a very similar condition following an abortion. The phlebitis in this case was also in left ovarian vein.

Dr. John G. Shelton, Telluride, Colorado, reports a case of phlebitis of left femoral vein following an aseptic appendectomy. Phlebitis began on the thirteenth day after operation. He also reports a case, in the practice of a neighbor physician, of left phlebitis following an interval operation for appendicitis.

Dr. Second had this complication in one of his cases (left femoral) following a clean herniotomy.

Cullen reports that on the twenty-first day following a vaginal hysterectomy one of his cases developed a phlebitis of left femoral vein. The next day she had a severe pain in the right side of the chest and crepitant râles and pleuritic friction sounds were detected. This patient recovered and the tenderness of vein and abnormal chest sounds disappeared. There was evidently an embolus, which found its way from femoral vein into right lung near its pleural surface. Cullen reports other cases in which the femoral and popliteal veins have been affected following operations for cancer of uterus.

Dr. A. L. Brittin, Athens, Ill., reports a case of acute fulminating appendicitis, followed by a phlebitis of left saphenous, the latter beginning on the twenty-third day after operation and was accompanied by frequent attacks of dyspnea lasting several minutes. This case recovered.

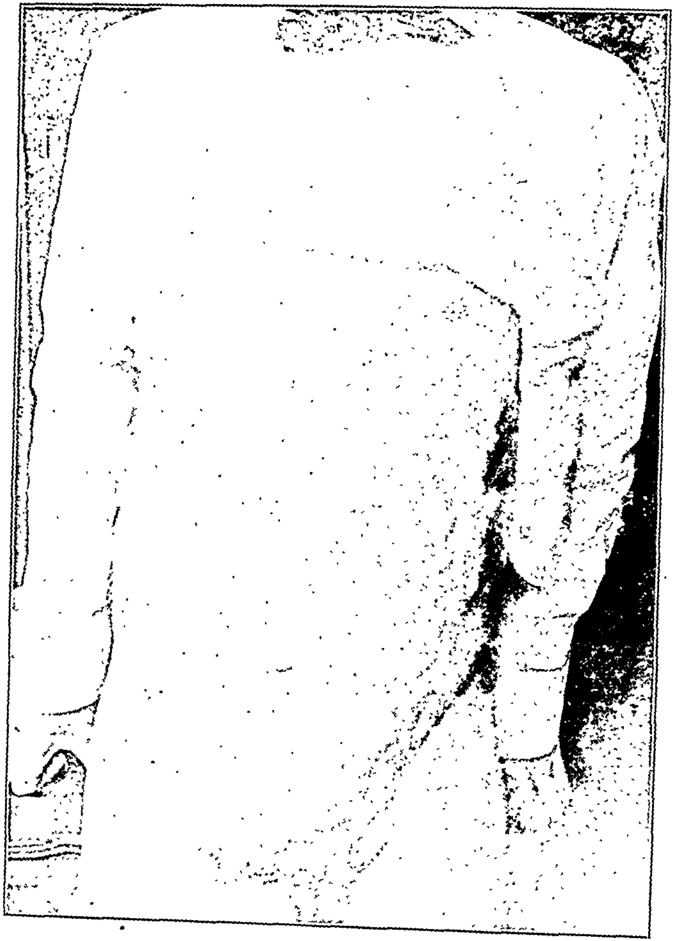

Fig. 4.—Occlusion of left common iliac vein from an ascending saphenous phlebitis following intravesical manipulation.

Dr. W. S. Thayer, Baltimore, in an admirable article on post-typhoidal thrombosis, says that in 39 cases of venous thrombosis, 26 cases occurred in left leg, 9 cases occurred in both legs, 5 cases occurred in right leg, 2 cases occurred in leg not recorded. He concludes his article by the statement: "It seems to me that the evidence is decidedly in favor of the idea that these cases of venous thrombosis are for the most part due to a primary phlebitis.

Heller reports 2 cases of phlebitis following a gonorrhea in a male patient, in both patients the left saphenous was the vein involved.

---

[3] Med. Rec., June 14, 1905.

somewhat akin to the reason for the prevalence of varicocele on the left side and the frequent affections of the left ovary in women. Many gynecologists claim that this is due to the fact that the left spermatic vein in man and left ovarian vein in women enter into the splenic vein at a right angle, whereas the right spermatic vein in man and the right ovarian vein in women enter into the vena cava almost directly, so that the venous flow going from the left testicle or left ovary passes around a right angle. This should be thought of in this connection.

Dr. A. H. Cordier said that Dr. Goldspohn's remarks would be applicable were this condition of thrombus of a primary character. This is not the case, it is secondary to the inflammatory conditions in the venous wall. The anatomic character could be easily explained were it of a thrombotic nature, but it is not of thrombotic origin. It is simply a mild type of infection. Inflammatory changes take place in the venous wall and this condition is secondary thereto.

SITE OF ORIGIN OF GALLSTONES.*

L. L. McARTHUR, M.D.
CHICAGO.

If excuse were necessary for again raising the discussion relative to the site of origin of gallstones, it might be found in the evidence offered by the actual specimen I herewith present, as well as by the anomalies its unique clinical history offers. So startling were the findings both at the time of operation and at necropsy that I feel justified in claiming your attention while presenting them for your consideration. I will first give as briefly as possible an abstract of the clinical history, leaving for future publication the more complete details, temperature chart, analysis, etc., and then such conclusions as may be drawn from the review of the current literature.

Patient.—M. G., Austrian, aged 25, clerk, single. Admitted to Michael Reese Hospital Nov. 28, 1904. Died Dec. 12, 1904, fourteen days after admission and on the twenty-third day of illness.

History.—Family history negative. Past history, "Always well and strong." Denies all previous sickness. No venereal history. Drinks some, but not to excess.

Present trouble of ten days' duration. Patient states that he "caught cold" two weeks previous to onset. Onset was sudden, with severe, cramp-like pain in right hypochondriac region. Pain localized and aggravated by deep inspiration and coughing. Tenderness on pressure. No icterus. Had a chill on third day, followed by high temperature. No nausea or vomiting, though an emetic had been given to induce vomiting. Appetite good until recently. Bowels regular. No hemoptysis. No night sweats. No urinary trouble.

Examination.—When patient entered hospital the physical examination showed only a slight tenderness in the epigastric region just below ensiform. Skin chocolate colored. Spleen palpable. Temperature 102.4 (rectal), pulse 92, respiration 20, leucocyte count 10,300; Widal partial. During his first ten days in the hospital his temperature ranged from 99 to 103. On the tenth day he had a chill lasting fifteen minutes, followed by a sudden rise of temperature to 105.6, dropping to 102.6 in an hour after being sponged, pulse ranging all the time from 70 to 90.

Six days after admission to hospital patient had an attack of severe epigastric pain with a slight icteric hue to skin. Small round tumor about the size of an egg was felt in the region of the gall bladder. Rectus muscle tense on right side. No radiation of pain to shoulders, but passes to back and lower thoracic region.

On the twelfth day he had another chill, followed by temperature of 105.6; leucocyte count 19,000, Widal partial. Urinary examination showed albumin, bile, hyaline, granular and epithelial casts.

Operation.—On the following morning, twenty-three days after first symptoms, he was transferred to the surgical department and immediately operated on. Operation under ether anesthesia. Bevan incision revealed a moderately distended gall bladder. No peritonitis. Palpation of common duct in the usual manner revealed a hard cylindrical tube one and three-quarter inches in diameter, which gave the impression of grasping the bodies of the vertebræ, so large and so hard was it. On opening the common duct after the usual packing off, by an inch incision, there escaped innumerable gallstones (246 were counted) of pea size, floating not in bile, but in pus of the same stinking character as characterizes an appendiceal abscess. As fast as the stones could be ladled out with a large gallstone spoon, more would appear, until, considering the desperate condition of the patient, it was deemed advisable to remove only those obstructing the duodenal end of the common duct. Two fingers could be passed along the duct. Large drainage tube inserted in the duct after the gall bladder had been emptied of a semi-translucent mucopurulent fluid and drainage provided. Closure of abdomen in usual manner with gauze supplemental drainage.

We have, then, in this case these remarkable facts: First, the total absence and denial of any former serious illness or infective fever. Second, with innumerable stones in ducts, but none in gall bladder, the patient had never a colic until his final illness. Third, the fluid first escaping from the incision in the common duct instead of bile was stinking colon bacillus pus. Fourth, the absence of stones in the gall bladder, coupled with the denial of ever having had a pain or an ache prior to his last illness, is sufficient evidence that these stones had never been in the gall bladder. Fifth, the postmortem findings demonstrate the existence of innumerable stones in the finer intrahepatic ducts, diminishing in size regularly as the ducts grow smaller.

A partial postmortem examination permitted fourth day after operation revealed:

First. Absence of general peritonitis.

Second. Drainage of gall bladder and common duct in site and efficient.

Third. Dilatation of the common duct excessive, permitting passage of three fingers.

Fourth. Narrowing of cystic duct but not complete occlusion.

Fifth. Many small stones still in common duct.

Sixth. Suppurative cholangitis extending into lesser hepatic ducts.

Seventh. Wherever incision is made into substance of the liver, calculi of varying size are to be seen in ducts.

Eighth. Death from septic cholangitis.

On analysis, gallstones consist of cholesterin alone, bilirubin calcium alone, or varying proportions of both, with cholesterin usually predominating. While bile normally contains minute traces of cholesterin, it never contains, in health, bilirubin calcium. The physiologic chemist, in recent years, has demonstrated that the source of cholesterin is in degenerative process affecting the cell protoplasm, columnar epithelium being that most prone to undergo this metamorphosis, hence the presence of cholesterin in various secretions like those of the bronchi, the nose, in the steatomata of the ear, the bile tracts, or in those neoplasms lined by columnar epithelium.

The biologist has demonstrated experimentally and the pathologist found by his research at necropsies that the influences necessary to induce these degenerative changes are resident in the protoplasmic poisons of somewhat attenuated bacterial organisms. When such irritants act on the epithelia, the latter are found to un-

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Dr. Trumbull, Valparaiso, Chili, reports a case of left saphenous phlebitis following a follicular tonsillitis.

Detachment of the thrombi, where such is formed, in these cases, is extremely rare, yet has occurred with a frequency sufficient to warn us in the management of these cases to avoid all known causes leading to pulmonary or cerebral emboli. These thrombi usually are non-suppurative, hence are not likely to undergo deliquescence and become detached from their moorings. A recognition of this fact admonishes us to avoid all mechanical methods that might lead to a forcible detachment of the thrombus, such as massage, too early muscular exertion, etc. Some of the postoperative pneumonias are undoubtedly due to infected emboli carried from inflamed and thrombolic veins. A more fatal condition may be brought about by an embolus in the brain from the same source.

Venous obstruction from a thrombus may lead to gangrene of the limb by an extension of the obstruction in both directions, thus preventing all collateral circulation. A termination so serious is extremely rare. In fact I have been unable to find such a case recorded where the phlebitis followed an abdominal operation. Where the disease extends or involves the internal iliac and obliterates that vessel, as it has been known to do, the anastomotic circulation is carried on through the internal mammary, the superficial epigastric, the external pudic and its corresponding vessel of opposite side. (Fig. 4.) Nature seemingly gets rid of the thrombus in this position by the same process of absorption as is the case with the fibrin extravasated in other tissues.

Massage should not be used in the early history of the disease for fear of dislodging fragments of a thrombus, thus causing embolic, pulmonary or cardiac symptoms of an alarming character or even sudden death. A patient suffering from a phlebitis should avoid all undue or violent exertion, as the detachment of a fragment of a thrombus may result in a fatal embolic injury of a cardiac or respiratory center in the floor of a fourth ventricle or a multiple infection of lung or other remote organs.

An increase of the calcium salts in the blood has been mentioned as a probable source of phlebitis and venous thrombosis, by increasing the coagulability of the blood. Sodium citrate has been recommended as a prophylactic agent by its tendency to decrease the powers of the blood to coagulate. Tavel recommends ligation of saphenous above inflamed portion in order to prevent embolism, a procedure I feel that will rarely, if ever, be necessary.

The acute symptoms of a phlebitis usually disappear within a few weeks under proper management, while the late history is one of a tedious recovery and the use of the elastic stocking extending over a period of months and sometimes years.

Elevation of the affected limb and bandaging it loosely and keeping it moist with witch-hazel or other cooling lotions, constitutes the local treatment for the acute phlebitis. The administration of cathartics and tonics completes the treatment of ordinary cases. Later, massage and the use of an elastic stocking may be necessary.

From various sources I have collected 232 cases. The tables appended show some very interesting facts. Of the 232 cases, phlebitis followed the following operations the number of times stated:

Nephrorrhaphy	9
Appendicitis, mostly so-called aseptic cases	27
Cholecystotomy	4
Oöphorectomy (cystic, cirrhotic, etc.)	16
Hysterectomy fibroids, so-called aseptic cases	69
Vaginal operations, character not stated	8
Alexander's operation	3
Hernia	4
Pyosalpinx	7
Pelvic operations, not specified	9
Abdominal and pelvic, character not stated	56
Ectopic pregnancy	4
Vaginal hysterectomy for cancer	9
Suspension of uterus	7
Splenectomy	1

SPECIAL FEATURES.

In 213 cases, left saphenous or femoral veins were affected.
In 8 cases, both left and right veins were affected.
In 11 cases, right veins alone affected.
In 182 cases, proximal part of vein first affected.
In 36 cases, distal part of vein first affected.
In 14 cases, portion of vein affected not mentioned.
In 166 cases, sepsis was not present at time of the operation.
In 56 cases, no mention of sepsis or asepsis was made.
In 10 cases there was pus present at time of operation. In the great majority of cases, the first symptoms appeared from the tenth to the fifteenth day.
In 6 cases, pleuritic and lung complications.
In 3 cases, sudden death occurred.

DEDUCTIONS:

1. This complication occurs in about 2 per cent. of all abdominal operations.

2. It follows operations on anemic patients most frequently, as in abdominal hysterectomies for bleeding fibroids.

3. Vaginal hysterectomies for the same conditions are rarely followed by this complication.

4. It is more liable to follow so-called aseptic operations where no drainage is used.

5. It is due to a mild type of infection and often to absorption of the necrotic pedicle at site of operation.

6. The disease attacks the left femoral or saphenous veins in over 90 per cent. of the cases.

7. Anatomic peculiarity of veins on left side have not been found that satisfactorily explains why the disease has a predilection for left side.

8. That a *locus minoris resistentiæ* exists in left saphenous and femoral veins is proved by the frequency of the involvement of these veins.

9. The disease is, primarily, an inflammation of the walls of the veins and the thrombus, when one forms, is secondary, as a rule.

10. Many cases of postoperative pneumonias, pleuritis and cerebral emboli have their origin in this source.

11. Treatment consists in elevation of affected leg, tonics, etc.

I wish to return my sincere thanks to the following surgeons, who have aided me very much in the preparation of this paper by sending me the reports of their postoperative cases of phlebitis and otherwise: Drs. Wm. S. Thayer, Maurice Richardson, Benjamin R. Schenck, A. H. Vander Veer, Weller Van Hook, Franklin E. Martin, Byron Robinson, A. J. Ochsner, A. H. Ferguson, W. J. Mayo, W. W. Keen, Wesley Bovée, W. D. Haggard, L. S. McMurtry, J. B. Murphy, Joseph Price, E. E. Montgomery, R. B. Hall, M. B. Ricketts, Edwin Walker, S. E. Lanphear, W. B. Dorsett, L. H. Dunning, H. L. Longyear, C. P. Noble, H. A. Kelly, J. M. Baldy, J. H. Carstens, R. T. Morris and A. C. Bernays.

DISCUSSION.

DR. C. O. THIENHAUS, Milwaukee, Wis., said that several years ago Lennander, from Upsala, published a paper on thrombosis and phlebitis of the lower extremities following operation and stated that this occurrence could be avoided by keeping the patient in the Trendellenburg position for from eight days to two weeks immediately following the operation. For the past four years Dr. Thienhaus has done this in all cases in which there is reason to believe that there might be a tendency to thrombosis of the lower extremities.

DR. A. GOLDSPOHN, Chicago, said that the reason for the greater frequency of this condition on the left side may be somewhat akin to the reason for the prevalence of varicocele on the left side and the frequent affections of the left ovary in women. Many gynecologists claim that this is due to the fact that the left spermatic vein in man and left ovarian vein in women enter into the splenic vein at a right angle, whereas the right spermatic vein in man and the right ovarian vein in women enter into the vena cava almost directly, so that the venous flow going from the left testicle or left ovary passes around a right angle. This should be thought of in this connection.

Dr. A. H. Cordier said that Dr. Goldspohn's remarks would be applicable were *this condition of thrombus of a primary* character. This is not the case, it is secondary to the inflammatory conditions in the venous wall. The anatomic character could be easily explained were it of a thrombotic nature, but it is not of thrombotic origin. It is simply a mild type of infection. Inflammatory changes take place in the venous wall and this condition is secondary thereto.

SITE OF ORIGIN OF GALLSTONES.*

L. L. McARTHUR, M.D.
CHICAGO.

If excuse were necessary for again raising the discussion relative to the site of origin of gallstones, it might be found in the evidence offered by the actual specimen I herewith present, as well as by the anomalies its unique clinical history offers. So startling were the findings both at the time of operation and at necropsy that I feel justified in claiming your attention while presenting them for your consideration. I will first give as briefly as possible an abstract of the clinical history, leaving for future publication the more complete details, temperature chart, analysis, etc., and then such conclusions as may be drawn from the review of the current literature.

Patient.—M. G., Austrian, aged 25, clerk, single. Admitted to Michael Reese Hospital Nov. 28, 1904. Died Dec. 12, 1904, fourteen days after admission and on the twenty-third day of illness.

History.—Family history negative. Past history, "Always well and strong." Denies all previous sickness. No venereal history. Drinks some, but not to excess.

Present trouble of ten days' duration. Patient states that he "caught cold" two weeks previous to onset. Onset was sudden, with severe, cramp-like pain in right hypochondriac region. Pain localized and aggravated by deep inspiration and coughing. Tenderness on pressure. No icterus. Had a chill on third day, followed by high temperature. No nausea or vomiting, though an emetic had been given to induce vomiting. Appetite good until recently. Bowels regular. No hemoptysis. No night sweats. No urinary trouble.

Examination.—When patient entered hospital the physical examination showed only a slight tenderness in the epigastric region just below ensiform. Skin chocolate colored. Spleen palpable. Temperature 102.4 (rectal), pulse 92, respiration 20, leucocyte count 10,300; Widal partial. During his first ten days in the hospital his temperature ranged from 99 to 103. On the tenth day he had a chill lasting fifteen minutes, followed by a sudden rise of temperature to 105.6, dropping to 102.6 in an hour after being sponged, pulse ranging all the time from 70 to 90.

Six days after admission to hospital patient had an attack of severe epigastric pain with a slight icteric hue to skin. Small round tumor about the size of an egg was felt in the region of the gall bladder. Rectus muscle tense on right side. No radiation of pain to shoulders, but passes to back and lower thoracic region.

On the twelfth day he had another chill, followed by temperature of 105.6; leucocyte count 19,000, Widal partial. Urinary examination showed albumin, bile, hyaline, granular and epithelial casts.

Operation.—On the following morning, twenty-three days after first symptoms, he was transferred to the surgical department and immediately operated on. Operation under ether anesthesia. Bevan incision revealed a moderately distended gall bladder. No peritonitis. Palpation of common duct in the usual manner revealed a hard cylindrical tube one and three-quarter inches in diameter, which gave the impression of grasping the bodies of the vertebræ, so large and so hard was it. On opening the common duct after the usual packing off, by an inch incision, there escaped innumerable gallstones (246 were counted) of pea size, floating not in bile, but in pus of the same stinking character as characterizes an appendiceal abscess. As fast as the stones could be ladled out with a large gallstone spoon, more would appear, until, considering the desperate condition of the patient, it was deemed advisable to remove only those obstructing the duodenal end of the common duct. Two fingers could be passed along the duct. Large drainage tube inserted in the duct after the gall bladder had been emptied of a semi-translucent mucopurulent fluid and drainage provided. Closure of abdomen in usual manner with gauze supplemental drainage.

We have, then, in this case these remarkable facts: First, the total absence and denial of any former serious illness or infective fever. Second, with innumerable stones in ducts, but none in gall bladder, the patient had never a colic until his final illness. Third, the fluid first escaping from the incision in the common duct instead of bile was stinking colon bacillus pus. Fourth, the absence of stones in the gall bladder, coupled with the denial of ever having had a pain or an ache prior to his last illness, is sufficient evidence that these stones had never been in the gall bladder. Fifth, the postmortem findings demonstrate the existence of innumerable stones in the finer intrahepatic ducts, diminishing in size regularly as the ducts grow smaller.

A partial postmortem examination permitted fourth day after operation revealed:

First. Absence of general peritonitis.

Second. Drainage of gall bladder and common duct in site and efficient.

Third. Dilatation of the common duct excessive, permitting passage of three fingers.

Fourth. Narrowing of cystic duct but not complete occlusion.

Fifth. Many small stones still in common duct.

Sixth. Suppurative cholangitis extending into lesser hepatic ducts.

Seventh. Wherever incision is made into substance of the liver, calculi of varying size are to be seen in ducts.

Eighth. Death from septic cholangitis.

On analysis, gallstones consist of cholesterin alone, bilirubin calcium alone, or varying proportions of both, with cholesterin usually predominating. While bile normally contains minute traces of cholesterin, it never contains, in health, bilirubin calcium. The physiologic chemist, in recent years, has demonstrated that the source of cholesterin is in degenerative process affecting the cell protoplasm, columnar epithelium being that most prone to undergo this metamorphosis, hence the presence of cholesterin in various secretions like those of the bronchi, the nose, in the steatomata of the ear, the bile tracts, or in those neoplasms lined by columnar epithelium.

The biologist has demonstrated experimentally and the pathologist found by his research at necropsies that the influences necessary to induce these degenerative changes are resident in the protoplasmic poisons of somewhat attenuated bacterial organisms. When such irritants act on the epithelia, the latter are found to undergo degenerative changes, with swelling of the cells, formation of myeloid bodies within the protoplasm, rupture, discharge of contents, and the subsequent appearance of cholesterin in the débris. Thus, in the lower animals, by attenuated cultures of the colon bacillus introduced in the gall bladder, it has been easy to induce such changes in the epithelium as to greatly increase the cholesterin contents of the bile tracts, with resulting cholesterin-stone formation. Active, unattenuated cultures of the colon bacillus or staphylococcus induce inflammatory changes, with pus formation and precipitated bile salts, but no stone formation, no cholesterin.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Bilirubin, the coloring matter of the bile, a sulphur-containing albuminoid derivative, is soluble in the soda salts of the bile. It is a product of the activities of the liver cell in health, not a degeneration product, which, under certain conditions, may be precipitated with a calcium base, making an insoluble body, bilirubin calcium, the other important constituent of the second group of gallstones. These conditions, as is the case with cholesterin, are most often those of bacterial fermentative action, though conceivable as occasionally due to a pathologic condition of the hepatic secretions, incident to age, poor metabolism, alkalinity of the bile, and the consequent precipitation of bilirubin calcium. The source of bilirubin, then, being in the hepatic cells themselves, the formation of bilirubin calcium stones is rendered possible in the very smallest bile ducts. This is most frequently the type of those stones found intrahepatically, as of the case submitted. The source of the calcium base with which the bilirubin combines, when precipitated by bacterial or other influences, is as yet a mooted question. Calcium salts exist in the bile normally, but normally do not combine with bilirubin. If, however, bacterial fermentative changes be induced in the bile, with consequent diminished alkalinity, bilirubin calcium is precipitated. Thus, it will be seen bacterial influences are the determining factors of stone formation, whether they be of cholesterin or bilirubin calcium. Of the former in the gall bladder and common ducts more especially; of the latter in the intrahepatic ducts, *probably*; in the gall bladder and common ducts *possibly*.

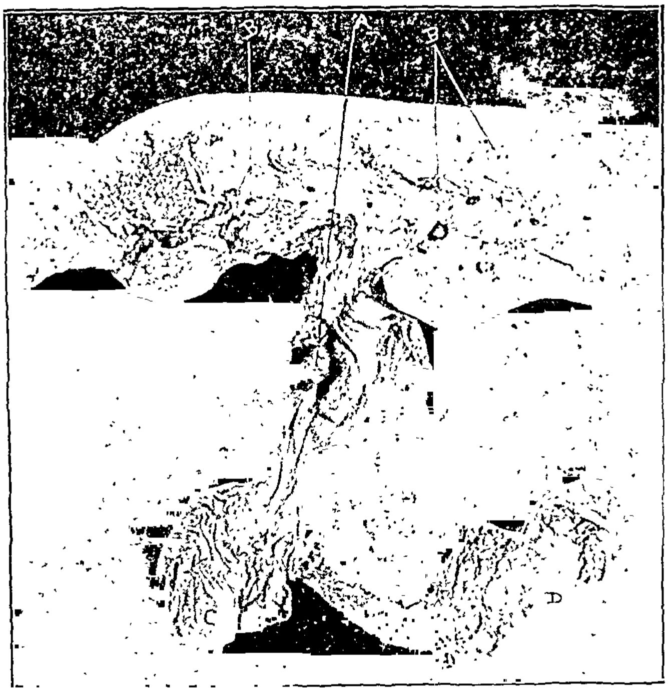

Fig. 1.—Frontal section of left lobe of liver with common duct leading down to duodenum and pancreas. Gall bladder removed. Notice: A, Large stones in common duct. BB, Intrahepatic stones in the different radicals. C, Duodenum. D, Pancreas.

We have thus seen the source of the gallstone constituents, but have considered only one of the factors essential to stone formation, which, taken alone, will never produce stone. There must be the other factor of stagnation of the bile stream either in the gall bladder and its mucoporous crypts or the ducts. If this be intermittent in character the growth of the stone will also be intermittent, and a laminated stone result. If continuous, the stone presents a more constant composition. It should be distinctly understood that stagnation alone, however produced, will not produce either variety of stone, but that to it must be added a mild bacterial infection, so mild as not to induce inflammatory reaction in the lining of the gall tracts, but sufficient to induce degenerative changes in the epithelial linings, or a diminished alkalinity of the bile by a fermentative change in its constituents, or both. The stagnation in the stream may be inflammatory, neoplastic, or in various ways mechanical, need not be continuous, must not be absolute. Since the flow in the gall bladder is not as active as in the ducts themselves, this is the site of election of the stone formation in many cases, but not, as well-known authorities yet teach, the only place.

The labors of Herter, Miyake, Welch, Hanot, Miszkowski, Chiaro, Gilbert and Cushing have, by an immense number of experiments, demonstrated the truth of the statements so far made, a review of which at this time is inopportune.

Of immense interest, however, is the nature of infective stone-forming elements and their manner of ingress into the bile tracts. This has been now demonstrated to be possible, either through a direct extension up the tracts from the intestines, or by a direct elimination with the bile, of organisms for the time being infecting the blood of the individual. It has long been known as true that the typhoid and other organisms can be recovered in the urine of the infected patient. It now is known that organisms are similarly eliminated by the liver cells, appearing in the bile, to excite, if very virulent, perhaps an acute cholecystitis or cholangitis; if attenuated by their passage through the blood, to slowly induce those changes in the mucosa favorable to the production of cholesterin, and act mechanically as nuclei for stones after having undergone the "clumping" influences which obtain in typhoid serum and secretions. Especial emphasis is here made to the typhoid organism as a factor in the formation of gallstones, first, because it was the earliest demonstrated organism to act thus; second, because 20 to 30 per cent. of all typhoids are followed by gallstones; and, third, because, while not particularly provocative of suppurative processes, it has shown itself to have a wonderful vitality, living in the human as long as 26 years (Billings). Its continued presence in the gall-bladder crypts slowly provokes those degenerative changes before referred to which result in the production of cholesterin.

When, on the other hand, the bacteria of the intestine gain access to the bile tracts by direct extension up the ducts, as can be so beautifully observed in the extension up Steno's duct in typhoid, they usually excite, as they do in the parotid, acute suppurative or gangrenous processes, and we have the presence of acute typhoid gangrenous cholecystitis produced by the same organism which, more attenuated in character, will produce stone.

What has been said of the typhoid organism occasionally obtains with the colon bacillus, and the nuclei of various stones proven to consist of them.

CONCLUSIONS.

1. All gallstones do not originate in the gall bladder.
2. The origin of cholesterin stones is probably in the gall bladder, with subsequent growths either in gall bladder or ducts where they may lodge.
3. Bilirubin calcium is the constituent of the smaller intrahepatic duct stones.
4. Calculi in immense numbers may have existed for months in the ducts without producing a symptom.
5. The surgeon need not reproach himself too much if there be recurrence of the symptoms after common duct drainage.

DISCUSSION.

Dr. C. O. Thienhaus, Milwaukee, Wis., agreed with Dr. McArthur that gallstones not only form in the gall bladder and in the cystic duct, but in the hepatic and common ducts as well, and that in those cases it is difficult to decide whether to perform a cholecystectomy or a cholecystostomy. Cholecystostomy, he said, is a much more justifiable operation because of the lesser danger connected with it.

Dr. M. H. Richardson, Boston, said that one of the most important points in connection with the surgical treatment of gallstones is the impossibility of finding and removing those concealed in the hepatic duct. The surgeon, therefore, should not reproach himself if, after he has removed all that he can find, symptoms pointing to other stones continue. The combinations in biliary diseases are numerous—the complications greatly exceeding those of disease of the appendix. Of gallstone disease we really know but little, and for what knowledge we have we must depend largely on the surgeon's observation of pathologic conditions during life. He has been strongly impressed by the importance of making observations, not only as to the seat of origin of gallstones, but as to symptoms caused by stones the situation and other attributes of which have been thus demonstrated. That gallstones are not always formed in the gall bladder itself two or three of his cases have clearly demonstrated. He illustrated the situation and probable seat of origin of the stones by blackboard sketches. In one case the stones were undoubtedly formed in the liver. In one instance, after the removal of a large number of stones from the dilated hepatic and common ducts, 150 were discharged through the tube; in another, after the removal of many stones from a hepatic duct as large as a gall bladder, each primary division of the hepatic duct was drained separately and the amount of bile from each half of the liver determined. In this case, as the diagram shows, the nidus of gallstones was perhaps the gall bladder, and the dilatation of the hepatic duct may have resulted from obstruction of the common duct by multiple stones. The practical point in connection with the seat of origin of gallstones is that the exploratory incision should be large enough to admit the hand. It is only in this way that the biliary tract can be extensively and thoroughly examined.

Dr. Robert F. Weir, Hague, N. Y., suggested another way of getting large incisions other than the one Dr. Richardson showed. The long vertical cut is made, but to achieve the ample room desired for free manipulation and vision of the anterior sheath of the section is divided transversely, the muscle pulled strongly to the left—when its posterior sheath is likewise divided transversely—this gives a large increase of operative space, but if more should be demanded the muscles of the abdominal wall to the right of the ventral invasion can be separated as has been shown by Dr. Richardson. The divided layers of the rectal sheath at the close of the operation are sutured, and this, with the replacement of the muscle, re-establishes the integrity of that portion of the abdominal wall. This procedure is similar to Dr. Weir's method in appendicitis incisions.

Dr. L. L. McArthur said that a very large drainage tube was introduced into the common duct in the case referred to, for several days gallstones kept pouring out; in fact, they came so constantly during the operation that the search finally had to stop. Dr. McArthur concluded that no reproach should be made against the surgeon if he has carefully explored the common duct, as the origin of the stones might be far out of reach, even when the surgeon has gone into the liver substance to a great depth. One can not always get all the stones no matter how careful the search.

Clinical Reports

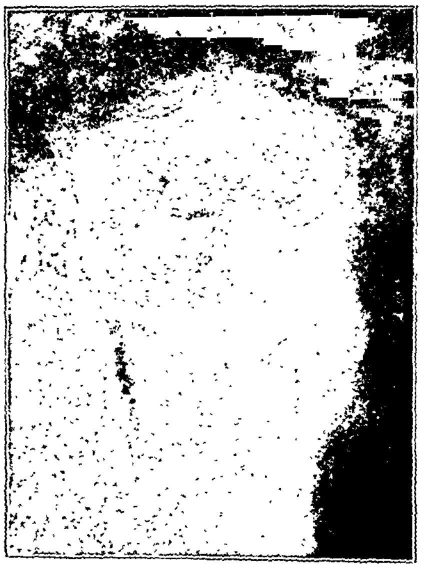
CONGENITAL MALFORMATION OF THE LEFT AURICLE AND OF THE EXTERNAL CUTANEOUS CANAL.*

EMIL AMBERG, M.D.

DETROIT.

Patient.—Mr. A. S., Russian, aged 32, was seen by me Oct. 13, 1905. He comes from Sakolko, in Grodno, Russia, and has been in the United States about six months. He is the father of three children who, according to his statement, are free from any malformation.

Description of Malformation.—The left auricle, as shown by the accompanying illustration, is arrested in its development. The ridge is 4.6 cm. long. The width varies from 11 to 7 mm., the height from 7 to about 5 mm., the lowest portion being about the middle of the ridge, which consists mostly of cartilage. Four distinct, blind and narrow canals can be made out by the probe. Two are found in the anterior fold between the cartilage and the skin, the first 11 mm., the second 28 mm. from the top, both pointing upward and backward, the first of them being about 5 and the second about 7 mm. long. A third canal is found in the middle of the ridge about 13 mm. from the top, showing scarcely any depth, and a fourth one in the posterior fold 22.5 mm. from the top presenting practically no depth. Besides these there are slight intimations of two canals in the posterior fold, one 29 and the other 34 mm. from the top, exhibiting only a trace of depth. The osseous canal seems to be filled with fibrous and cartilaginous tissue. The mastoid process is well developed.



Showing malformation of left auricle.

Hearing.—Politzer's acoumeter is heard about one inch from the left ear by air conduction, and around the canal by bone conduction. Blake's 512 tuning fork is not heard by air conduction, but by bone conduction. The Weber test is localized in the right ear. Hartmann's 4096 tuning fork is neither heard by air nor by bone conduction. The right ear appears to be normal.

---

* Demonstrated before the Wayne County (Detroit) Medical Society, 1905.

CASE OF INFECTION WITH THE RAT-TAILED LARVA OF THE DRONE FLY.

E. L. K. HANBY, M.D.
Surgeon to Sloss Sherfield Steel & Iron Co.; Assistant Surgeon to Louisville and Nashville Railway, Alabama Great Southern Railway, Southern Railway, and the Birmingham Railway Light and Power Co.
BESSEMER, ALA.

Dr. Boston, Philadelphia, found on postmortem in a child which died in convulsions and great agony a parasite, which he sent to Professor Stiles of Washington, D. C., who replied that the specimen was a species of the genus *Helophilus* or *Eristalis.* Dr. Boston gives no history or treatment of his case further than that the child died in great agony and convulsions. With the exception of this case I fail to find that any other author mentions this species of parasite. I feel that this disease is very grave and that perhaps it is often met without being recognized. The case which I wish to report came under my personal observation, and the pain and agony was something terrible. I have never seen any human being suffer more than did this child.

History.—On Sept. 12, 1905, I was called to see a little negress 18 months old, at Sloss Mines, Ala. The child was sitting in its mother's lap, crying loudly and pulling out the hair from the front of its head; the eyes were glaring. The child seemed to be terribly frightened; saliva was pouring from its mouth, and it had the appearance of an insane child. The child's mother could do nothing to quiet her. I gave the patient a hypodermic of morphin, 1/16 of a grain, and in ten minutes she was quiet, so I proceeded to examine her further. The mother told me that the child had suffered three weeks previously from teething, so her physician had told her, but he had treated her ever since without any apparent result, and the child had continued to grow worse. She would crawl on her abdomen, and in this position she would stop crying and seem to be easy, and would finally drop off to sleep for a period of half an hour. She would then awake in great pain, and very much frightened and nervous. She cried continually, pulled her hair and scratched her buttocks. These attacks of agony would last from 15 to 30 minutes and then she would be quiet for about one hour, except that she would be very fretful for an hour or two.

The surroundings were very good; the location of the house is 635 feet above sea level. The water is taken from a covered natural spring. The child's diet consisted of fried ham, bacon, eggs, greens, Irish potatoes and cornbread; she also drank a great deal of buttermilk.

Examination.—The child was very anemic and emaciated; the eyeballs were sunken far back in the socket. Temperature was 99.8; pulse 88. The tongue was coated, moist and trembling. The lungs were in good condition except for a slight cough; the heart's action was good. The abdomen was very much distended, and was tense like a drum. The child was having and had had for the past two weeks, frequent passages of mucus, with great tenesmus; moving of bowels did not relieve the pain. The child passed about 32 ounces of urine a day, and on examination I found the specific gravity 1.026; reaction, acid; no sugar nor albumin, but an excess of phosphates. There was no pain on urination.

Treatment.—I prescribed (and with good results:)

℞. Hydrarg. chlor. mitis.............grs. iii 2|
Santonin ....grs. iss 1|
Mt. et. ft. chart. No. 3. Sig. 1, powder every 2 hours.

This was followed by a tablespoonful of castor oil and two drops of turpentine.

Result.—Six hours afterward she passed twenty-four live worms, which lived two and one-half days without food. These worms or parasites were grayish in color, one and one-half inches long, from head to tip of tail, and half an inch in diameter. They had two horns, one on each side of the head, sucker-shaped mouths, and were very vicious; they would snap at a straw or at anything held close to the head. The tail of each was one-half inch in length and had a stinger or horn on the end of it. The tail was held straight up when crawling, and the worms could crawl very fast. These worms looked very much like new-born mice, with the exception of the legs, which were very much like those of a thousand-leg worm. After the passage of the worms, the child rested well that night; the next morning her mother showed me the worms. I was utterly astounded and told her that I knew no human being could pass mice, which they resembled very much, so she brought in enough eye witnesses to convince me that she spoke the truth. I gave the child the following:

℞. Hydrarg. chlor. mitis ....grs. iii 2|
Salol |
Santonin, āā ....grs. iss 3|
M. et. ft. chart No. 3. Sig., 1 powder every hour.

This was followed by one tablespoonful of castor oil. In four hours the child passed four more worms; they were dead. Since that time (Sept. 13, 1905) she has passed no more worms to date (Oct. 27, 1905). And at present is in good health and is gaining in weight rapidly. She sleeps well at night, and is entirely well, in my opinion. As an after treatment, I gave her calomel in broken doses, 1/6 grain once a day for seven days, and followed this with a tonic of iron, strychnin, quinin and cod-liver oil. She is taking this tonic now.

[The parasite in question is the "rat-tailed" larva of the drone fly (*Eristalis tenax*), or of some closely allied form. The drone fly is common about flowers. The larva lives in foul water, feeding on decaying vegetable matter. The tail is a telescopic tube which can be lengthened or shortened as necessity dictates; at its end there is a rosette of hairs which may spread out on the water and keep the larva from sinking; through this tube the larva obtains air when the body is submerged. Some allied larvæ live in rotten wood. This organism is not normally a parasite, but it might be swallowed accidentally. It was described as a parasite of man by Brera in 1809, under the name *Cercosoma* (misquoted by some authors as *Conosoma*). If the larvæ were actually passed from the child in this case, as claimed by the mother, the infection was doubtless purely accidental and probably took place through the drinking of some stagnant water.—Editor.]

OBSTRUCTION OF BOWELS FROM GALLSTONE.

R. H. POWELL, M.D.
Superintendent of the Grafton City Hospital.
GRAFTON, W. VA.

Obstruction of the bowels from gallstone is of infrequent occurrence, being variously estimated from 8 to 15 per cent. of all intestinal obstructions. I may be pardoned, therefore, for reporting a case occurring in the practice of Dr. Ithamar Davisson, of Flemington, a village ten miles from this city, and in which I was called in consultation the night previous to the day of operation.

History.—A woman, aged 56, multipara, rather corpulent, had had stercoraceous vomiting for two days; there had been no movement of the bowels for five days, with severe pain in the epigastric region. Patient gave a history of having had attacks of gallstone colic about eight years previously, but had had no recurrence until the beginning of present illness. When I saw the woman she had a temperature of 100.4 degrees; the pulse rate was 120. Early the next day she was brought to the Grafton City Hospital, where she was immediately prepared for operation.

Operation.—A median incision six inches long was made. The abdominal wall was very thick. The intestines were highly injected and very much distended. I drew out through the incision a few coils of intestine, and then passed my hand down to the right inguinal region, where a hard mass was felt. On withdrawing the mass I found that it was *within* the lumen of the bowel, about ten inches above the ileocecal valve. Immediately above this point the bowel was distended and highly injected. Near the cecum the intestine was normal in appearance. One assistant was instructed to grasp the bowel on either side of the *obstruction. After thoroughly* walling off the abdominal cavity by packing with gauze wet in hot normal salt solution, a longitudinal incision was made directly over the obstruction, which proved to be a gallstone. After thorough cleansing, the opening in the intestine was closed by a continuous Lembert suture, reinforced by a second row. The bowel was cleansed, the omentum drawn down, and the abdomen closed with silkworm gut and chromicized catgut.

Remarks.—The patient made a rapid and complete recovery. The gallstone was egg-shaped and measured one and one-half inches in the longitudinal and one inch in the short diameters.

COMPOUND FRACTURE OF THE VAULT WITH LOSS OF BRAIN SUBSTANCE.

A REPORT OF TWO CASES WITH RECOVERY.

MAURICE KAHN, M.D.
Surgeon to St. Vincent's Hospital.
LEADVILLE, COLO.

I feel that no apology is necessary in reporting the following cases, as they are of sufficient rarity to merit attention. Cranial injuries, moreover, occupy a place of the first surgical importance, notwithstanding that only 2 or 3 per cent. of all fractures are found to be of the skull; for the reason that the skull contains so vital an organ, and that there is a mortality of from 20 to 25 per cent. in all vault fractures with or without depression.

It behooves us, then, to give our most serious thought to such cases, the treatment of which appears to be not so well comprehended as the treatment of similar injuries to bones in other situations. Why this should be is not easily explained; certainly the brain, so intolerant of violent usage, the one organ above all others that can not be maltreated with impunity, that promptly resents insult, not alone deserves, but demands proper treatment in the event of its injury. If it were not for brain implication in so many of the cranial fractures, these fractures would have no claim to a more prominent position than similar damage to the long bones. As is well known, the serious aspect assumed by these cases results, not from the extent of the fracture itself, but from the probability of brain involvement, which is the more conspicuous by reason of the higher degree of fragmentation of the inner plate than of the outer. This is particularly evident in gunshot wounds, the ex- [illegible] often discloses an unexpected splintered or depressed inner table. The relative infrequency of fracture at a distance in these cases is probably explainable on the ground that the force of the vulnerating object is expended at the point of impact.

In deciding whether or not to explore it is wise to bear in mind the danger of pus formation outside the dura, the easy infectibility of the diploë, and the chance of the inner table being comminuted or depressed, even though there be but slight evidence of injury to the external table. Hence, before making any but the most superficial examination, it is well promptly to shave the head and to scrub the scalp and one's hands as though going into the cranial cavity; then one is prepared, if it should be found necessary, to proceed with whatever measures may be deemed essential without danger of infection, and thus also to avoid dangerous delay fraught, as it often is, with such possibilities for harm.

Case 1.—I saw this patient, a strong, well-developed man of 40, at midnight on May 18, 1899, about thirty minutes after the accident, which resulted from a quarrel, during which the patient was struck on the head with a woodman's ax. A wound had been inflicted 3⅜ inch long, 1½ inches above the nasion; the anterior angle five-eighths of an inch to the left of the median line; the posterior angle was three-quarters of an inch to the left of the median line.

Treatment.—The head was shaved, scrubbed with chlorinated soda solution, etheral soap and bichlorid of mercury. On exploration there was found the cleanest-cut wound I have ever seen in bone; it had the appearance of a clean-cut incision in any of the soft parts, or as though made by a saw. Within the wound were a few tiny particles of brain tissue. A resolute effort was made to ascertain if splintering, comminution or depression of the inner plate had occurred, including careful probing with a trephine probe, but no evidence of such a condition could be detected. This is the more remarkable, as one familiar with skull fractures, with a knowledge of the inflicting weapon and the probable force used in delivering the blow, would naturally expect to find that considerable more damage had been done the inner plate than had been done the outer. That splintering did not occur is seemingly convincing testimony to the keen edge of the penetrating blade. The wound was sewed up tight, resulting in primary union. While we have no means of ascertaining whether or not harmful adhesions have formed, nevertheless there is at this time (six years following injury), no symptomatic evidence favoring such a theory.

Case 2.—This patient, a robust man of 28, was seen about two hours after the accident, and presented a small, round wound a half-inch above the right superciliary ridge 1½ inches from the median line. There was a second wound about three inches posterior to the first and a trifle mesially. These injuries were said to be self-inflicted from a 38-caliber gun. The wounds were characteristic of bullet wounds; that of entry, the anterior one, being round and small compared with that of exit, the posterior one, which was larger and lacerated. The area surrounding the anterior wound was powder stained, showing the close proximity of the revolver when discharged.

Treatment.—After cleansing the scalp, during which processs considerable brain tissue escaped, the two openings were connected by a straight incision which was prolonged backward to permit thorough exploration. Considerable comminution and depression was then noted. The opening in the skull was enlarged with DeVilbiss' forceps to permit the elevation and extraction of fragments of bone imbedded in the brain. During this procedure a portion of the bullet was also removed, and more brain tissue unavoidably lost. Profuse diploic oozing from the posterior angle was a disagreeable feature attending the operation. This area was packed, just sufficient room being left in suturing to permit protrusion of the gauze. The wound healed by first intention, except the packed area, which, however, closed without difficulty. At this time (nine months following injury), no untoward symptom appears.

It is to be borne in mind in giving prognosis, however, that epilepsy has been known to develop even many years after skull fracture; and also, that traumatic epilepsy most often follows wounds of the frontal and parietal regions.

To the tyro, the presence of a wound of exit might be taken as positive evidence that the entire bullet had passed out, and be misleading to the extent of his concluding that it probably inflicted slight injury to the skull and its contents. The proximity of the two wounds might also lend color to the belief that the bullet had entered at a slight angle, been deflected by the bone, which it possibly had not injured to any great extent. An immediate exploration will always safeguard against error, and should invariably be performed in doubtful cases of head injury. The experienced surgeon might expect to find irreparable damage to the brain by reason of the revolver having been held at such close range at the time of its discharge. As a rule, gunshot wounds of the skull (except those resulting from small caliber weapons) are hopeless because the explosive effect on bone and fluid—or semifluid-containing cavities, frequently insures extensive fissuring and comminution of the skull and great or excessive contusion of its contents.

SOME OBJECTIONS TO THE PASTEURIZATION OF MILK.

The question as to whether milk is better food for children in a raw or Pasteurized state is easily answered in a few large cities where supervision of dairies is properly carried out and the standard of dairy cleanliness high. Under such circumstances, there is no question that the raw material is the best in every way. Any-one who will take the trouble to follow the newspaper reports of our large cities will find that in most of them there appear from week to week accounts of the fining of milkmen or dairy companies for putting on the market milk which shows evidence of chemical or bacterial abnormalities or which contains some kind of preservative. A visit to the dairy farms in the neighborhood will usually make it apparent why such evidences of uncleanliness are so commonly found. The average dairyman knows little, and apparently cares less, about the steps necessary to insure clean milk, and the average dairy employe does not appreciate them at all. Practical dairymen invariably claim that the price paid for milk in the large cities is so small, and the expenses of transportation and handling milk so great, that they can not afford to be as clean as is necessary to secure uncontaminated milk. The conduct of a clean modern dairy requires a large outlay for buildings and apparatus, and a much larger force of helpers than is to be found in the [illegible] dairy of the present. In order to procure clean [illegible] our cities, therefore, we must either raise the [illegible] milk or resort to some artificial method of ren[illegible]g it innocuous. Unfortunately, any increase in the [illegible]ce of milk would fall most heavily on the more pro[illegible]ic poorer classes, and for this reason is objectionable, though it might be possible to educate the general public up to the desirability of this step. Meanwhile, the question of Pasteurization is of importance.

The advocates of Pasteurization claim that the effect of the process is to destroy the ordinary lactic acid bacilli which cause souring of the milk, to kill disease germs, to prolong the keeping power, and at the same time to produce no marked change in the taste or digestive quality. There is still some discussion, we believe, as to the power of ordinary Pasteurization to destroy tubercle bacilli, an important question if Behring's views as to milk transmission are substantiated. There is still a question as to whether Pasteurization does not destroy or inhibit certain natural ferments in milk which assist in its digestion. Many competent observers, perhaps it would be fair to say most of them, believe that Pasteurization does have this effect.

One of the commonest tests applied by health boards to determine the fitness of milk for consumption is the acidity test. The estimation of the number of bacteria is a tedious process requiring special apparatus, and, in a rough way, there is a parallelism between the amount of acid and the number of lactic-acid bacteria. For this reason, the acidity test, which is simple, is in constant use, and a milk not showing definite signs of souring to the unaided senses, is often condemned on account of high acidity. Bergey[1] has recently shown that reliance on the acidity test will lead to grave error if applied to Pasteurized milk. After Pasteurization the bacteria which survive are the spore formers, and most of these belong to the *Bacillus subtilis* group. These organisms can increase to enormous numbers without raising the acidity of the milk very markedly. For instance, in one of Bergey's tests a sample of Pasteurized milk contained over 148,000,000 bacteria, and had not one-half the acidity necessary for its condemnation. It is true that these particular bacilli produce in time coagulation of the milk, but the changes indicative of spoiling which are appreciable by smell and taste, are not apparent, so that before coagulation a milk with a very high bacterial count would be passed if the acidity test alone was used. It is likewise true that the group of bacteria classed under the general head of *Bacillus subtilis* are not generally regarded as pathogenic, but there are instances, especially in eye diseases, in which they have been known to take on pathogenicity. In any event, they produce changes in the milk which render it less digestible, and like other non-pathogenic bacteria their products introduced into the gastrointestinal tract may be fully capable of setting up severe irritation. Dr. Bergey's work is an argument against the use of Pasteurized milk, and one which should be considered.

CANCER COMMUNICABILITY.

One of the interesting phases of the discussions on cancer at the recent annual meeting[2] of the New York State Medical Association was the fact that the majority of the surgeons who took part in the discussion on the etiology and prophylaxis of cancer, insisted on the possibility of the disease being communicated from one person to another. It has long been a perplexing matter to explain why certain houses have seemed to be much more liable to have cancer patients than others, in spite of the fact that the successive families that moved into them bore no relationship to each other. It has been pointed out, too, that cancer seemed to spread along water courses and, having found lodgment in a certain part of a country, to rage there with more virulence than in other parts, though no climatic or dietetic conditions

---

1. Proc. of the Path. So. of Phila., 1905, vol. viii, p. 102.
2. Medical News, Nov. 4 and 11, 1905.

could be suggested to explain this apparent increase of virulence.

There is no doubt at all in the minds of any surgeon of extensive experience that cancer can be and often is autoinfectious, that is, that it may be communicated from one portion of a cut surface of a patient to another portion of the incision. It has often been noted, moreover, that cancer of the lip has been transferred from one lip to the other, and even more wide distributions have apparently been observed, apart from metastases.

Of course, the question of cancer communicability is extremely important. There are many possibilities of error in the consideration of the subject. Cancer is so common as to make the disturbing factor of coincidences almost impossible of elimination. According to the last census, nearly one in thirty of all those who die in the United States die from cancer. Under these circumstances it is easy to understand that not infrequently a person who has been in close association with a cancer patient will afterward die with the same disease, yet without any necessary causal connection. In fact, if this did not occur, in about one in every fifty cases, or a little more, there would be grave doubt thrown on the census statistics. The persons who wait on cancer patients, apart from nurses, are usually of nearly the same age, that is, are brothers, sisters, husbands or wives, and so they have reached the age where there is a special liability to cancer. While there is no reason therefore, for thinking that we have sufficient evidence to disturb those in attendance on cancer cases with the hideous thought that perhaps they are exposing themselves to some slight additional risks of acquiring the disease, there is every reason for further study of this subject.

General practitioners throughout the country can do more to furnish valuable statistics than the operators in large cities. Every case of cancer development, in which there is or has been intimate association with a previous cancer case, should be reported. More than one country physician knows of series of cancer cases that have occurred along a particular water course, or in successive farms along the same road. All of these cases, even though they may seem to be only coincidences, should be reported. From the data thus obtained, perhaps some definite idea of the amount of communicability of cancer that exists may be estimated. That it is not high is sure; if it exists at all, we should know it, and the sooner the better for humanity. Only the general practitioners can solve the problem in the immediate future. It may seem to some of them that the notion of cancer communication is so improbable as not to deserve attention. It must not be forgotten, however, that scarcely twenty-five years ago, in spite of the fact that tuberculous houses had been pointed out, and tuberculous neighborhoods mapped out, there was a general impression that tuberculosis was not communicable, though we now recognize it as a distinctly contagious disease.

THE TYPHOID SPINE.

Recent histologic and bacteriologic studies of the bone-marrow, not only in typhoid fever, but also in influenza, smallpox and other infectious diseases, have shown this tissue to be so frequently affected that it is remarkable that clinical symptoms on the part of the bones are not more often noted in such affections. That they have been noted to some extent can not be denied, but that a general recognition of bone lesions as a result of infectious diseases has not yet taken place can be easily proved by a glance through recent medical literature. The lack of recognition of such lesions is probably due in the main to two reasons, one being that the pains which form so prominent a symptom of such cases are referred to the muscles or nerves, the other that these post-infectious bone lesions tend to heal spontaneously and without the formation of pus.

The lesion which at present usually goes by the name of "typhoid spine," as the diffuseness and uncertainty of this appellation would indicate, has been a subject of a good deal of dispute. There are some who hold that the lesion is a neurosis, whilst others believe it to be due to definite organic changes. As is well known, the condition is one whose main symptoms are pain, generally in the lumbar region, and stiffness of the spinal column. The affection may appear during the fag end of a typhoid attack, or may not occur until several months later. The pain is practically always the initial symptom, it is often quite severe, and usually radiates to the hips, thighs, or abdomen from its seat in the lumbar or dorso-lumbar region.

The recent article of Fluss[1] shows that evidences of more than functional disturbance are to be recognized in quite a large percentage of the cases. Nerve root symptoms are far from rare. Radiating pains, muscle spasm not limited to the spinal muscles, and disturbances in the reflexes must all be interpreted as nerve root signs. Other evidences of organic change are not wanting, and among these must be mentioned rise of temperature at the onset of the pain, paresthesiæ, and in not a few cases actual bony deformity.

It is difficult to reconcile these various symptoms with a neurosis. Of course, marked symptoms of organic disease are often absent, but it must be remembered that the spine is not an easy structure to investigate. If lesions attack the anterior aspect of the spinal column it is readily understood that they may be difficult of detection. There is in many ways a marked resemblance between the method and time of onset and the course of cases of so-called typhoid spine and the post-typhoid lesions which attack parts of the skeleton which are superficial and easily investigated. Their time of onset is similar, fever is apt to occur at the onset in each case, spontaneous remissions are common in both instances, and suppuration not infrequently fails to occur in the definite post-typhoid lesions of the long bones. On the other hand, the mere fact that individuals suffering from these peculiar spinal symptoms are neurasthenic or hysterical does not prove that all their symptoms are due to a neurosis. The evidence so far adduced from the reported cases of typhoid spine is, we think, strongly in favor of the view that this condition is due to organic changes. Just what these changes are we can assume, but can not prove. In the light of our knowledge of post-typhoid bone lesions elsewhere it seems fair to conclude that in some instances we are dealing with a perispondylitis, and in others with actual disease of the vertebræ. It is certainly safe and conservative to regard all such cases for the present as organic in origin, and to outline the treatment with this point in view.

MENTAL DISEASES ASSOCIATED WITH ARTERIOSCLEROSIS.

The hyperplastic degenerative process designated arteriosclerosis may be looked on as the anatomic expression of old age, mature or premature. Secondary to it the nutrition of the tissues generally suffers with atrophy of parenchymatous structures and increased production of interstitial tissue. These alterations naturally are attended with varied functional disturbances, taking for example, in the sphere of the nervous system, the form of impaired mental, motor and sensory activity. Changes of a related character may be due, likewise, to atrophy of nerve cells, perhaps from toxic influences, although here, too, the vessels are not likely altogether to escape. A good deal of attention has been given to this subject in recent years, and an interesting exposition of the relations between sclerosis of the cerebral vessels and various forms of mental disease is given by Dr. Albert M. Barrett,[1] supplemented by a detailed account of illustrative cases, with description of the lesions.

The lesions are usually focal, although they may be diffuse, and they give rise to a more or less distinctive symptom-complex of varying character. Miliary aneurism, with or without rupture, thrombosis and embolism, conditions often associated with arteriosclerosis, for the purposes of the present discussion, are left out of consideration.

The disease of the vessels may give rise to cerebral atrophy, to subcortical encephalitis, to perivascular gliosis or to degeneration of cortical vessels with destruction of nerve-tissue. The clinical manifestations referable especially to the brain include diminished mental endurance, impaired mental power, enfeebled memory, headache, vertigo, aphasia, syncopal, apoplectiform or epileptiform attacks, paresis and dementia.

The disorder is to be differentiated especially from paretic dementia and from simple senile dementia. The presence of vascular disease, a history of similar disease, perhaps associated with mental disturbance, in the ancestry, and freedom from syphilitic infection are in favor of the arteriosclerotic affection. In the latter, symptoms referable to vascular change, such as attacks of vertigo or "shocks," usually appear earlier than mental phenomena, while delusions are more common and more pronounced in paretic dementia. The pupillary reactions and the kneejerks are less commonly enfeebled in arteriosclerotic than in paretic dementia. The lesions and, therefore, the symptoms, of paretic dementia are diffuse, while those of arteriosclerotic dementia are usually focal.

The differentiation of senile dementia is exceedingly difficult, as this condition is almost invariably, though not necessarily, associated with the lesions of arteriosclerosis. The symptoms comprise gradually increasing change of character, with forgetfulness, inclination to fabulate, loss of judgment and disorientation.

OREGON AND ORGANIZATION.

Not one physician who is interested in the general welfare of his profession can afford to miss reading the report on professional conditions in Oregon which is presented in this issue[1] by the chairman of the Committee on Organization. It is pertinent to call attention to one of the great benefits of Dr. McCormack's visitations to the various states, and that is the comparative estimate of medical affairs which results from the personal investigation of them all by one experienced eye. In no other way is it possible so readily to obtain a true picture of the situation. Then each state presents certain commendable features that all the rest should know about in order to imitate if possible. Also in nearly every state ill conditions have arisen which others will wish to avoid by knowing the antecedent causes. So in the present report on Oregon we find record of one county society that is a model for all, but a general state of professional disintegration whose etiology others will study in order to avoid. Because of internal factional disputes within the profession of the chief city there is total paralysis of effort to perform public duty and to improve medical conditions. The evil results of dissension among otherwise capable and honorable men are vividly portrayed. The medical practice act is ineffective and unenforced, and in consequence of the low qualification standard the profession is being recruited from those who fail to pass the examinations of other states. Good men, disliking personal strife, stay out of the organization and thus greatly weaken it. As a whole, there is no real organization, the average of the profession is low, and the medical schools are weak. Quacks flourish, and here and there is evidence of commissions and of contract and lodge practice. The picture could not well be more unattractive, but no doubt exposure of the evil state of affairs will stimulate the capable men to enter the organization and to control it for the good of the public and of the profession, putting aside or absorbing those who have heretofore spent their time in internal dissension. The regeneration should be made easy by reason of the fact that in the state there is one model county society whose example and success are bound to win adherents for real organization. There is not a state in the Union where the lessons of Oregon can not be studied with profit. Everywhere the lessons of this diagnosis of professional conditions should be fixed firmly in our minds, the good to be imitated and the evil to be avoided.

PURE FOOD BILL.

One of the most important bills before the United States Congress this year, from the standpoint of public health, is the Pure Food Bill. This bill has already been introduced, according to press reports, but whether it is the same measure as was before Congress last year we do not know. It is encouraging to know that President Roosevelt has recommended such legislation in his message to Congress, which is an advantage. He says:

> I recommend that a law be enacted to regulate interstate commerce in misbranded and adulterated foods, drinks, and drugs. Such law would protect legitimate manufacture and commerce and would tend to secure the health and welfare of the consuming public. Traffic in food stuffs which have been debased or adulterated so as to injure health or to deceive purchasers should be forbidden.

It is to be hoped that every physician will realize the importance of the measure and will do all he can to overcome the opposition that will come from the organized interests that will be affected. At the present time we would suggest that it might be a good plan for each one to write to his congressman and senator and ask for a copy of the bill. It will at least make them realize that there is such a bill and that some of their constituents are interested in it. There will be no open opposition to the measure; it is the other kind that may be expected.

WHAT IS "THE PACE THAT KILLS"?

This question has been correctly answered a good many times, so that its revival would seem superfluous were it not for the fact that the terms of the problem are continually forgotten. Recent statistics in our two largest and most "strenuous" cities have appeared to show that the mortality from diseases of the nervous system is not increasing. Still, it is much the fashion to charge premature and unanticipated deaths to "the strenuous life" and to "the hurried life." Newspapers, and even some medical men, read into these unfortunate mischances a meaning that rather appeals to our national pride. We are gravely told that the hurry and strain of American commercial life are reaping a harvest of premature decay and death. Of course, if this deduction is warranted by the facts, the "captains of industry," great and small, must be the chief sufferers. But, as a matter of common observation, the real leaders in the great business transactions of our period, as a rule, work no longer than from 10 a. m. to 3 or 4 p. m. on five days of the week. These men also take more outdoor exercise and recreation than ever before was the case. Among them, too, long vacations are the rule. Premising that there is lack of reliable statistics on the subject, it may well be doubted if the fashionable and rather flattering conclusions are in any respect correct. It is not business that kills, but intemperate living of every kind. It is the excessive play of the emotions and the unrestrained gratification of the appetites, not the hard work and the rush, that chiefly contribute to the premature fatalities. The true answer, then, is but a modernized variant of the ancient "wine, women and song." The times have changed, ways of life are different, but now, as heretofore, hard work is beneficial to health, and, as always, there is the penalty for excess in the pleasures of life. The trained physician who witnesses these untimely deaths is not deceived. The myocarditis, the arteriosclerosis, the nephritis, the pneumonia tell to the practiced eye the same tale that is so obvious when we are confronted with an ataxia, a multiple neuritis, a general paresis. Such being the case, it is disingenuous, to say the least, to delude the public into a belief that mere hurry and activity produce such results. Duty and responsibility demand that we at all times keep the old truths well to the front. The true moral must ever be drawn from the execution of these penalties, that the world may benefit by their deterrent effect.

TEA DRINKING.

Considerable has been said of late in some English publications, and extensively quoted in this country, about the evil effects of tea drinking in causing physical degeneracy. We have always with us some dietetic reformers who put the ban on tea as well as on the more harmful stimulants. THE JOURNAL has already expressed itself on this subject, but in view of the above facts a word more may not be amiss. There is a possibility that the decoction of tea leaves improperly made may be injurious to certain organizations, but that a mild tea infusion of sufficient strength to give all its needed exhilarating effects is harmful we can not believe, and certainly not if it is used in due moderation. Excessive tea drinking, like excessive bread eating, is not to be commended; excess in anything is necessarily injurious. There may also be certain conditions of the system, generally morbid ones, in which the taking in of any considerable amount of the chemical substances contained in tea is harmful, but such are not the conditions of the average individual. As counter to this we may mention the sanitary advantages of the germicidal effect of boiling the drink, which wards off more sickness than it could by any possibility produce. It is this which makes habitable the germ-saturated soil of China, and the degenerating effects on the very virile but exclusively tea-drinking population are not very manifest. There are few, if any, more innocent and attractive flavorings possible for hot drinks than that of the tea leaf. Reformers also should bear in mind the fact that in condemning such innocent drinks as tea they are furnishing, in a way, ammunition for the advocates of less innocent ones, who are always ready to utilize any side arguments that are afforded them. Tea, like many other useful things, may not be a valuable element in an infant's diet, and is liable, like every other good thing, to be abused, but it has few objectionable qualities and may be counted as one of the things adding to the material happiness of life.

Medical News

ALABAMA.

Damage by Fire.—The offices of Drs. Thomas F. Robinson, Lucian A. Spencer and Hanby, Bessemer, were badly damaged by fire November 17.

Emergency Hospital Opened.—The Montgomery Emergency Hospital, which is said to be one of the finest and best equipped institutions in the South, has been opened to receive six negroes suffering from smallpox.

Personal.—Dr. T. Miles Leatherwood and family have returned to Tuscaloosa from an extended stay in Denver.——Dr. and Mrs. Rhett Good, Mobile, have returned from Detroit.——Dr. Gaston J. Griel has been elected city physician of Montgomery.——Dr. William G. Harrison and daughter, Talladega, have returned from Europe.

ARKANSAS.

Hospital Threatened by Fire.—The State Lunatic Asylum, Little Rock, was in danger November 25 from fire which broke out in the laundry of the institution.

Fifth District Meeting.—The Fifth Councilor District Medical Society met in Camden November 9, and after a literary program was entertained by the physicians of the city at a banquet.

Hot Springs Doctors Convicted.—A jury in the Federal Court November 1 decided that Dr. S. C. Van Leer, Hot Springs, had been guilty of violating the regulations governing the Hot Springs Reservation by prescribing hot-water baths without having registered. Sentence was deferred.——Drs. James S., Fred and George Fulton, Hot Springs, were arraigned November 8 on the charge of violating the act of Congress governing the prescription of hot-water baths by non-registered physicians. After hearing the evidence Dr. James S. Fulton was fined and his two sons $5 each.

Suit and Injunction.—By order of the Mena Board of Health the public schools of the city were ordered closed until November 20 on account of diphtheria, and on November 16 the board issued an order that all public meetings such as schools, churches and operas should be prohibited for the time being. The pastor of the Lutheran private school, despite this order, opened his school, and was arrested and fined for disobeying the order of the board, whereupon the pastor brought an injunction suit against the board, which was decided by restraining the board from interfering with the school in any way.

Government Should Control Springs.—Dr. Martin Eisele superintendent of the Hot Springs Reservation, in his annual report, states:

> The present system of operating the baths through the medium of private lessees is in conflict with public opinion and incompatible with local conditions, and that the government should, as soon as practicable, consistent with existing conditions, assume absolute and complete control of this reservation and operate the bathing interests under government supervision and control thereby eliminating the spirit of commercialism which is manifested under present conditions; and, through scientific equipment, perfection of system, order, discipline and intelligent direction, extend the benefits to be derived from the healing waters, with rates adjusted to cover prudent operating expenses and necessary improvements.

He also makes the following recommendations:

> I have the honor respectfully to recommend that a white man and white woman of special educational skill in the administration of the baths, be employed to operate the male and female departments of the various bathhouses as special bath directors, who shall supervise and direct the proper execution of bathing directions when furnished by physicians to their patients, or when the applicant is without medical direction.
>
> Under present conditions, there is no one to whom the patient can appeal concerning the baths, except the bath attendant. Especially is this true in the female department, as a manager can not invade the privacy of this department, and if he did he has no special qualifications to properly direct the various forms of the baths required under competent medical direction. In view of the importance and growing demand for more intelligent administration of the baths, I respectfully urge that this recommendation be given careful consideration.

CALIFORNIA.

Diphtheria.—The Gardner school, San José, has been closed for fumigation on account of the prevalence of diphtheria.

Personal.—Dr. John Crawford, Arroyo Grande, has been appointed pension examiner, vice Dr. George B. Nichols, San Luis Obispo, deceased.——Dr. Frederick W. Hatch, Sacramento, has been reappointed superintendent of state hospitals.——Dr. D. C. Strong, Redlands, has been appointed superintendent of the San Bernardino County Hospital, succeeding Dr. Theodore D. Kellogg, Chino, removed.——Dr. John S. Hogshead, Laytonville, has been appointed medical superintendent of the Mendocino county farm.——Dr. William C. Hopper, San Francisco, has returned after two years in Nome, Alaska.——Dr. A. N. Loper, Fresno, has been elected chairman of the local board of health to succeed Dr. George L. Long, resigned.——Dr. Isaac A. McCarty, Corona, has resigned as physician of Riverside County, to take effect Jan. 1, 1906.——Dr. Norman Bridge, Los Angeles, has assumed medical direction of the Esperanza Sanatorium, Altadena.

COLORADO.

Create Medical Library.—The Las Animas County Medical Society has decided to found a medical library in Trinidad for the use of the physicians in southern Colorado.

October Deaths.—The total number of deaths in the state during October was 782, equivalent to an annual death rate of 15.69 per 1,000. Typhoid fever caused 48 deaths; diphtheria, 7, and scarlet fever, 5.

Presentation.—On the sixtieth birthday of Dr. S. Edwin Solly, Colorado Springs, his professional associates presented him with a silver loving cup handsomely engraved and inscribed to "The Youngest of Us All."

Dissolution of Hospital Staff.—The general staff of physicians at St. Francis Hospital, Colorado Springs, has been dissolved in purusance of a change of policy in the conduct of the institution whereby all physicians in the city will have the same standing at the hospital.

Communicable Diseases.—During October 369 cases of typhoid fever, 94 of scarlet fever, 63 of diphtheria and 9 of smallpox were reported. Compared with September, this shows a decrease of 5 cases of smallpox and an increase of 40 of diphtheria, 65 of scarlet fever and 35 of typhoid fever.

Personal.—Dr. Ortus B. Adams has been appointed mine surgeon for the Colorado Fuel & Iron Company at Tercio.——Dr. S. B. Schloz, Bessemer, has resigned from the dispensary staff of the Colorado Fuel & Iron Company and will locate in Colorado Springs.——Dr. Matt R. Root, Denver, surgeon general of Colorado, has gone to New York.——Dr. John Elsner, Denver, has returned from a vacation trip in the East.——Dr. and Mrs. A. Mansfield Holmes, Denver, have returned from a trip to Ohio.

CONNECTICUT.

Communicable Diseases.—During October 157 cases of measles were reported in 13 towns; 114 cases of scarlet fever in 32 towns; 5 cases of cerebrospinal fever in 4 towns; 120 cases of diphtheria in 29 towns; 8 cases of whooping cough in 5 towns; 175 cases of typhoid fever in 46 towns, and 35 cases of consumption in 16 towns.

October Deaths.—During the month of October 1,166 deaths were reported to the State Board of Health. This was 30 less than for the previous month, 1 less than for October, 1904, and 28 more than the average for October in the five years preceding. This mortality is equivalent to an annual death rate of 14.1 per 1,000. Diseases of the nervous system caused 154 deaths; heart disease, 128; consumption, 101; accidents and violence, 83; diarrheal disease, 82, and pneumonia, 74.

Personal.—Dr. Charles H. Glover, Norwalk, has been appointed a member of the medical staff of the Connecticut Hospital for the Insane, Hartford.——Prof. H. W. Conn of Wesleyan University, Middletown, has been appointed state bacteriologist.——Dr. Charles A. Lindsley, New Haven, has resigned as secretary of the State Board of Health, to take effect after the removal of the office of the board to Hartford.——Dr. Joseph A. Coogan has been reappointed health officer of Windsor Locks.——Dr. Herman P. Hessler, New Haven, sailed for Europe on the *Blucher* November 7.

DISTRICT OF COLUMBIA.

Distinguished Surgeons Visit Washington.—Dr. Adolf Henle, professor of surgery in the University of Breslau, Germany, and his assistant, Dr. Otto Fittig, after a visit in Washington, sailed for Germany November 21 on the *Kronprinz Wilhelm*.

Personal.—Dr. George Tully Vaughan, assistant surgeon general United States Public Health and Marine-Hospital Service, Washington, has resigned in order to devote his entire time to the practice of surgery.——Dr. Louis Mackall, Georgetown, slipped and fell November 15, fracturing one of the bones of the foot.——Dr. James J. Kilroy, Washington, has resigned his position on the staff of the gun factory in the Navy Yard to devote his time to the practice of medicine.

Deaths of the Year.—The District Health Officer in his annual report gives the total number of deaths in the District for the year as 6,221, of whom 3,580 were white and 2,641 negroes.

The mortality was equivalent to an annual rate of 19.61 per 1,000 for the entire population, or of 16.03 for white and 27.92 for negroes. The chief cause of death was consumption, which claimed 832 victims, or 13.37 per cent. of all deaths. Diarrhea of young children caused 323 deaths; heart diseases, 562; paralysis, 62, and pneumonia, 556.

FLORIDA.

Loss by Fire.—The building in Mayo owned by Dr. Robert L. Goodbred was destroyed by fire September 18 at a loss of $1,500, fully covered by insurance.

Personal.—Dr. John B. Maloney, Key West, has been appointed first lieutenant and assistant surgeon, Florida State Troops, and assigned to duty with the Second Infantry.——Dr. J. Whiting Hargis, Pensacola, who has been seriously ill with septicemia, has recovered.

GEORGIA.

New Sanatorium.—The Cordele Sanatorium will be opened about January 1 by Drs. Thomas J. McArthur and Walter E. Edwards, Cordele.

New Hospital.—The trustees of the Presbyterian Hospital, Atlanta, have recommended that the hospital association build a steel fireproof hospital to cost $50,000.

Personal.—Dr. Fred Low, Augusta, was presented with a handsome pair of cuff buttons by the executive force of the City Hospital on the occasion of his departure for New Mexico.——Dr. Theodore E. Oertel, Augusta, was elected permanent chairman, and Dr. M. A. Clark, permanent secretary, of the tuberculosis committee appointed by the Georgia Medical Association.——Dr. DeSaussure Ford, Augusta, resigned from the chairmanship of the governing board of the City Hospital. Augusta, November 1, and Dr. W. Harry Goodrich was elected his successor.——Dr. Noel M. Moore has been appointed a member of the board vice Dr. William H. Doughty, term expired.

ILLINOIS.

Epidemic Diseases.—Diphtheria is reported to be epidemic in Walker Township, Hancock County, where three schools have been closed.——An epidemic of smallpox is reported from Jerseyville, where 12 cases have been discovered among the employés of a shoe factory. A strict quarantine has been established and the State Board of Health is in control of the situation.

To Investigate Water Supply.—At a conference November 21, attended by the secretary of the State Board of Health, Edward Bardow, director of the state water supply, and J. A. Harmon, sanitary engineer, plans were adopted for the systematic investigation of the water supply of the state. This investigation will include the sewage purification system in operation in 20 cities of the state, and reports from other states and from foreign countries.

Personal.—Dr. Samuel A. Graham has been reappointed chief of the staff of physicians at the Illinois Eastern Hospital for the Insane, Kankakee.——Dr. James L. Lowrie, Lincoln, narrowly escaped death in a collision between his buggy and some freight cars which were making a flying switch. His buggy was struck by the cars, and the horse, buggy and man were dragged or pushed along the track for 60 feet in front of the cars. Fortunately Dr. Lowrie escaped with only a few scratches and contusions.

Chicago.

Personal.—Dr. Daniel H. Williams delivered a series of lectures at Meharry Medical College, Nashville, beginning November 6.

The Smells of Chicago.—The Health Department, after an investigation of the various foul smells which infest the city, has found seven centers of pollution: The stock yards, stables, sewage, tanneries, malt-drying plants, unclean freight yards, and rendering plants.

November Mortality.—During November 2,065 deaths occurred, equivalent to an annual mortality of 12.56 per 1,000. Pneumonia caused 301 deaths; consumption, 249; nephritis, 187; violence, including suicide, 147; acute intestinal diseases, 112, and cancer, 106.

Deaths of the Week.—There were reported to the Department of Health for the week ended December 2, 483 deaths, equivalent to an annual mortality of 12.65 per 1,000. The deaths were 12 more than for the previous week and 33 more than for the corresponding week of 1904. Consumption caused 67 deaths; pneumonia, 62; heart diseases and nephritis, each, 40; intestinal diseases, 31; violence, including suicide, 25; cancer, 23, and nervous diseases, 22.

Additional Facts.—Dr. Henry J. Burwash requests the publication of additional facts regarding the suit against him, notice of which was made in the last issue of The Journal. He states that he was not sued for performing an unnecessary operation, but for making a partial autopsy without authority of the mother of the deceased; that permission to make the autopsy was given by an elder brother of the deceased, but the court held that the mother was the only person to grant the privilege; and that in the postmortem examination the body was not mutilated, but an incision an inch and one-half to two inches longer than the original incision was made; that only a digital examination was made through this opening, and that no organs were removed.

INDIAN TERRITORY.

Convicted of Manslaughter.—Dr. J. W. Davenport, Oakman, who shot and killed William Gaines, a mail carrier, in a neighborhood quarrel, has been convicted of manslaughter.

Western District Physicians Meet.—At the meeting of the Western District Medical Association at Muskogee November 14 Dr. Floyd E. Waterfield, Holdenville, was elected president; Dr. J. Hutchings White, Muskogee, secretary; Dr. Jesse L. Blakemore, Muskogee, treasurer. Sapulpa was selected as the next place of meeting.

INDIANA.

Medical Equipment Transferred.—The medical equipment of the Fort Wayne Medical College has been shipped to Indianapolis to the Medical Department of Purdue University.

Removed Diphtheria Sign.—Dr. Clara Harbamal, Corydon, who tore down a diphtheria sign, placed on a house in that town by the local authorities, will be prosecuted for violating the health laws of the state.

Personal.—Dr. Morton L. Bridge, Van Buren, has been recommended for appointment as a member of the Grant County pension board, to succeed the late Dr. Eli M. Whitson, Jonesboro.——Dr. Fred R. Clapp, Ligonier, coroner of Noble County, has resigned.——Dr. Brose S. Horne, health officer of Marion, who has moved to Indian Territory, has resigned.——Dr. Albert H. Combs has been appointed secretary of the Marion Board of Health.——Drs. W. H. and Jay Nusbaum have left Auburn and will locate in Las Vegas, N. M.——Dr. Corydon R. Richmond, the oldest resident of Kokomo and the first mayor of that town, celebrated his ninety-seventh birthday anniversary November 22.

Epidemic Diseases.—During the past week a large number of cases of diphtheria have developed in Corydon and the public schools of the town have been ordered closed.——Fort Wayne reports 36 cases of smallpox, and as the isolation hospital has been burned, many houses are quarantined. Dr. Albert H. Macbeth, the city health commissioner, has turned his barn into a temporary isolation hospital.——An epidemic of intestinal indigestion resembling la grippe is reported from Richmond, with 200 to 300 cases.——Scarlet fever is said to be raging at Hillsboro. About a dozen cases are under treatment and 2 deaths have occurred from the disease.——It is estimated that there are 75 cases of tonsillitis in Shelbyville.——The Junction schoolhouse near Flatrock, Washington Township, Shelby County, has been closed on account of diphtheria.

IOWA.

Dipsomaniac Hospital to Open.—The new Iowa Hospital for Inebriates, at Knoxville, will open about December 15. About 83 patients will be placed under treatment at that time.

Epidemic Disease.—Smallpox is reported from Fayette County, 2 cases being under treatment in West Union and 3 cases at Eldorado.——Scarlet fever is prevalent in Sioux City, and at present more than 60 cases have been reported to the health department.

Southeastern Physicians Meet.—At the thirty-fifth annual meeting of the Southeastern Iowa Medical Society, held in Burlington, November 23, the following officers were elected: President, Dr. Frank M. Fuller, Keokuk; vice-presidents, Drs. J. H. Chittum, Wapello, and James S. Gaumer, Danville; secretary and treasurer, Dr. Charles P. Frantz, Burlington, and censors, Drs. John F. Herrick, Ottumwa; George P. Neal, Fort Madison, and William S. McClellan, Morning Sun. The society decided to meet next year in Burlington.

KENTUCKY.

Physician Wins Suit.—In the suit of T. N. Franklin against Dr. Robert N. Whitehead, Fulton, for $15,000 for alleged malpractice, the federal court at Paducah decided in favor of the defendant November 22.

Epidemic Disease.—The majority of the country schools in McLean County have been closed on account of the prevalence of diphtheria and scarlet fever.——Smallpox has broken out in Pineville. Five cases have been reported and the public schools have been closed.

Personal.—Dr. D. D. Eads, Paris, has moved to Chicago.——Dr. Herbert H. Hunt, Mayfield, was kicked by a horse November 17, fracturing his leg.——Dr. Abiah M. Cartledge, Louisville, who has been seriously ill with pneumonia, is now said to be recovering.——Dr. William A. Rice, Fallsburg, has gone to Redlands, Cal.

LOUISIANA.

New State Hospital to be Opened.—The new Louisiana Hospital for the Insane, Pineville, now nearing completion, will be formally opened December 20, when 500 inmates of the Insane Hospital of the State of Louisiana, Jackson, will be transferred to the new institution. Dr. George A. B. Hays, formerly superintendent of the institution at Jackson, will be superintendent of the new asylum.

Personal.—Dr. Hermann B. Gessner, surgeon in charge of the Seventh Ward Marine Hospital headquarters, New Orleans, was presented by the emergency committee of the Seventh Ward with a silver loving-cup November 6.——Dr. Thomas Y. Aby, assistant quarantine officer at Quarantine, at the mouth of the Mississippi, has resigned, owing to ill-health.——Dr. Arthur W. De Roaldes, New Orleans, has returned after a five months' visit to France.——Dr. Rudolph Matas, New Orleans, has returned after a visit to the North.

Tulane College Opens.—The Medical Department of Tulane University of Louisiana, New Orleans, opened November 6 with a lecture by Dr. Abraham L. Metz. The following changes in the faculty are announced: Dr. Paul E. Archinard, demonstrator of microscopy, has been made assistant professor of diseases of the nervous system; Dr. Oliver L. Pothier, for eleven years senior assistant demonstrator in the microscopical laboratory, has been made demonstrator, with Drs. Joseph D. Weis, Isaac I. Lemann and Maurice J. B. Couret as assistants; Dr. Joseph Hume has been chosen lecturer and clinical instructor on venereal and genitourinary diseases; and Dr. Samuel M. D. Clark has been elected lecturer and clinical instructor on gynecology and obstetrics.

MAINE.

Personal.—Dr. Charles E. D. Lord, Biddeford, has moved to San Francisco.——Dr. Samuel B. Hunter and family, Machias, have gone to Seattle for the winter.

Diphtheria.—The prevalence of diphtheria is causing uneasiness in the town of Mexico, where the schools have been ordered closed on account of the disease.

Hospital News.—Biddeford will probably secure a hospital through provisions in the will of the late Moses E. Webber. It is expected that $75,000 will be available for this purpose.

College Opens.—The eighty-sixth annual course of lectures at the Medical School of Maine, at Bowdoin College, Brunswick, began October 23.——Drs. Frederick H. Gerrish and Alfred King have been transferred to the Portland branch of the school and their places have been taken by Drs. Walter E. Tobie and Wallace W. Dyson, Portland, and Dr. Hiram L. Horsman, Augusta.

Penobscot Physicians Meet.—The Penobscot Medical Association held its annual meeting and banquet at Bangor, November 21. Dr. Seth C. Gordon, Portland, was the guest of honor and delivered an address on "The Relation of the Physician to the State." The following officers were elected: Dr. Everett T. Nealey, Bangor, president; Drs. Arthur J. Bradbury, Old Town, and J. Albert Lethiecq, Brewer, vice-presidents; Dr. Bertram L. Bryant, Bangor, secretary and treasurer; and Drs. Daniel McCann, Atwell W. Swett and John B. Thompson, all of Bangor, standing committee.

MARYLAND.

Personal.—Dr. Thomas W. Koon is critically ill with blood poisoning at Cumberland.

Tuberculosis Fund Grows.—Contributions to the funds being raised by the Maryland Tuberculosis Association now amount to $792.50.

Builds Cottage.—Jacob Epstein, Baltimore, has had erected at the Hospital for Consumptives, near Towson, a new building which, in his honor, will bear the name "Epstein Cottage." It cost $1,000 and was planned after the style of building used for the treatment of consumptives in the Adirondacks and elsewhere.

Residence Burned.—The suburban home of Dr. William Gray, Chevy Chase, was burned to the ground November 21, with a loss of $10,000, partially covered by insurance.

Baltimore.

Smallpox.—Several cases of smallpox have occurred recently in South Baltimore.

Personal.—Dr. Randolph Winslow has been elected president of the North Carolina Society.——Dr. E. Linden Mellus has taken a villa near Naples, where he will spend the winter.

The Nostrum Question.—Mr. Samuel Hopkins Adams, who has recently rendered the public such a service by his exposure of patent medicine frauds through a series of articles in *Collier's Weekly*, addressed the Baltimore City Medical Society December 5 on "Medical Support of Nostrums."

Osler to Return.—Dr. William Osler will leave England about December 16 and will be in Baltimore January 5, where he will remain through the month. His visit probably has connection with the system of medicine which he is about to publish, in which he will have the assistance of Dr. Thomas McCrae.

Book Auction.—On November 28 the sale of autograph books took place at the Arundel Club by the Quarter Club for the benefit of the Mountain Sanitarium for Consumptives at Mount Airy, Md. Among books sold were those by Drs. S. Weir Mitchell and William Osler. The wit of Mr. Bonaparte and Mr. France, the auctioneers, drew a large crowd and a large sum was realized.

MASSACHUSETTS.

Fire Damage.—The offices of Drs. John C. Irish and Robert E. Bell, Lowell, were damaged by fire and water November 3.

Diphtheria.—The Brockton Hospital has been closed and placed under quarantine on account of an outbreak of diphtheria.

Leper Hospital.—The five lepers in the state have been transferred to Pekikese Island. The State Board of Charities has imported from India a supply of leproan which will be used for treatment of these lepers. Dr. Louis Edmunds, Harwich, associate medical examiner of Barnstable County, has resigned to become superintendent of the leper colony.

Bequests.—The will of the late Edward Walker leaves in trust an estate of nearly $1,000,000, one-third of the income from which is devised to the Springfield Hospital.——By the will of Mrs. Caroline H. Webber $1,000 is bequeathed to the Dickinson Hospital, Northampton.——The late Robert Carruthers, Lawrence, has left legacies of $500 each to the Lawrence General Hospital, the Lowell General Hospital and the Blackburn Infirmary, Lancashire, Eng.

Suitcase Suspect Acquitted.—A verdict of not guilty was returned December 2 by the jury in the case of Dr. Percy D. McLeod, Boston, charged with being an accessory after the fact to the illegal operation which resulted in the death of Susanna A. Geary, the victim of the "suitcase tragedy," and with concealing the crime. William E. Hunt and Louis W. Crawford, who pleaded guilty to being accessories after the fact in this case, were sentenced to terms of not less than six nor more than seven years in the state penitentiary.

MICHIGAN.

Detroit Personal.—Dr. Isaac L. Polozker, physician of Wayne County, has resigned and will take a long postgraduate course.——Dr. Herman Kiefer celebrated his eightieth birthday November 19.

Harison Re-elected.—Dr. Beverly D. Harison, Sault Ste. Marie, was reappointed a member of the Michigan State Board of Registration and Medicine for the term 1905 to 1909, and in October last was re-elected secretary of the board.

Physician Acquitted.—Dr. J. J. Sweetland, Mottville, Berrien County, who was indicted more than a year ago by the federal government, charged with destroying a rural mailbox, was tried November 21, found not guilty and discharged.

Ill and Injured.—Dr. James Eakins, Alpena, was taken suddenly ill November 26, and is regarded as being in a serious condition.——Dr. Charles W. Isaminger is critically ill with cerebral hemorrhage at his home in Alpena.——Dr. Charles H. Lewis, Jackson, sustained severe bruises about the head and body in a runaway accident November 21.——Dr. James W. Freeman, Saginaw, is critically ill.

Epidemic Diseases.—The Fifth Ward school, Ann Arbor, was closed by the health officers November 15 on account of the prevalence of scarlet fever.——The Board of Health has decided to close the schools of Gladstone on account of an epidemic of diphtheria. There are said to be more than 50 cases at present in the city.——In Detroit last week 16 cases of diphtheria and 11 cases of scarlet fever were reported.

Ann Arbor Hospital News.—The university regents have decided to build an addition to the University Hospital at an expense not to exceed $14,000, to constitute a ward for diseases of the eye, ear, nose and throat and to be in charge of Drs. Parker and Canfield.——The university regents have refused to allow a detention hospital for contagious diseases to be erected on the same grounds as the University Hospital.

MINNESOTA.

Personal.—Dr. Ole G. Hagen, Butterfield, has been appointed a physician on the staff of the Mount Lake Hospital.——Dr. John C. Boehm, St. Cloud, has been appointed chairman of the medical advisory board to the university board of regents.

Physicians Express Gratitude.—The Hennepin County Medical Society has addressed a letter to Mr. Al. J. Smith, prosecuting attorney of Hennepin County, expressing the appreciation of the members of the earnest work of the official in prosecuting those engaged in illegal and criminal medical practices.

Hospital Notes.—The first sod on the site of the State Tuberculosis Sanatorium at Walker was turned November 21 by the chairman of the state board of control.——The Maternity Hospital, Minneapolis, was damaged by fire to the extent of $300 November 1.——The bazaar held at the West Hotel, Minneapolis, cleared nearly $2,000 for the Northwestern Hospital.

NEW YORK.

School Quarantine Lifted.—The six schools in Woodhaven and Union Course, which have been closed on account of diphtheria, have been reopened.

Rabies Prevalent.—Within the past ten days three persons have been sent from Buffalo to the Pasteur Institute, New York City, to be treated for bites from rabid dogs. Since February 15 more than a score of persons have had to go to New York from Buffalo for treatment.

Down on Hazing.—Dr. Roswell Park has written a strong letter of protest to each of the secretaries of the secret fraternities of the Medical Department of the University of Buffalo, concerning class rushes, class conflicts and hazing, in which this mark of rowdyism is absolutely condemned, and urging the societies to co-operate with the college authorities to abolish these evils.

New York City.

Contributions to Hospitals.—Contributions to the Woman's Fund of the General Collection for the Associated Hospitals have been officially reported and amount to over $2,000.

Large Hospital Fair.—The receipts from the Jewish Hospital fair in Brooklyn, which was opened by Governor Higgins in the Twenty-seventh Regiment Armory November 27, were over $40,000 at the end of the second day, and it is confidently expected that from $75,000 to $100,000 will be realized by the close of the fair.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended November 25, 406 cases of tuberculosis, with 162 deaths; 326 cases of measles, with 11 deaths; 310 cases of diphtheria, with 31 deaths; 155 cases of scarlet fever, with 11 deaths; 65 cases of typhoid fever, with 9 deaths; 17 cases of cerebrospinal meningitis, with 7 deaths, and 121 cases of varicella.

Water Plans Opposed.—At the hearing on the plans for extending the water supply of New York City by drawing on the Catskill watershed unexpected opposition developed. There were fifty or sixty protests from various towns and villages along the course of this watershed filed, and more are promised. It seems likely that the board will condemn the plan or refer it back to the city commission for amendment.

Pneumonia and Measles.—The Health Department announces that this is the "measles year" and that this disease is usually accompanied by a decided increase in pneumonia; hence they are redoubling their efforts to combat these affections by urging a fight against dust and by greater activity in the anti-spitting crusade. The public has been warned against cold, alcohol and fatigue as the three direct invitations to pneumonia.

NORTH CAROLINA.

New Sanatorium.—The Tuberculosis Sanatorium established by the Royal League at Black Mountain has been completed and is open for patients.

Personal.—Dr. Marshall H. Fletcher, Asheville, has returned after a trip to New York.——Drs. Carl V. Reynolds and Jere Cook, Asheville, sailed for Europe November 15.

Additions to Sanatorium.—A new wing has been added to the Broad Oaks Sanatorium at Morganton, which will be devoted to private pay patients. Dr. Hugh Thompson, Reedsville, has been appointed assistant resident physician to the sanatorium.

Correction.—In a recent issue of THE JOURNAL it was stated that Dr. M. Avery, Salisbury, had been recently convicted of defrauding the government of large sums and had been sentenced to a term in the federal penitentiary. We are informed by our North Carolina correspondent that there is no such person in Salisbury as Dr. M. Avery, but that some weeks ago a distiller named D. M. Arey was convicted and sentenced as noted.

Need More Room for Insane.—It has been suggested by the lay press that the insane hospitals of the state are receiving and treating as patients in their wards persons other than indigents. Under a strict construction of the statutes only indigents are legally admissible to the state hospitals for the insane, but practically the letter of the law has been so ignored that 97 per cent. of the inmates of state institutions are treated at the public expense, while an average of more than 69 per cent. of the inmates are cured. Yet there has been a constant and steady accumulation for many years of incurables in each of the hospitals until, with the increase of insanity, the accommodation provided in state institutions has become insufficient to accommodate the insane of the state. Dr. P. L. Murphy, superintendent of the Western Hospital for the Insane, Morganton, has repeatedly called the attention of the legislature to this imperative need, and now, at last, additions to the State Hospital at Raleigh are being made, and an investigation is to be instituted by the governor to ascertain the financial status of the inmates cared for at the public expense, with a view of possibly securing more space for indigent patients.

OHIO.

New Cincinnati Hospital.—The new city hospital ordinance approving the plans and specifications for 18 of the 35 proposed buildings, at an estimated cost of $1,750,000, and a bond issue to start work at once on the administration building and one ward building, has been passed unanimously by the city council.

Public Lecture on Consumption.—Under the auspices of the Academy of Medicine of Toledo and Lucas County, Dr. S. A. Knopf, New York City, will deliver a lecture at Memorial Hall, Toledo, December 14, at 8 p. m., to which the public is invited. Dr. Knopf's subject will be "The Tuberculosis Problem; How It May be Solved."

Personal.—Dr. W. E. DeCourcy, Cincinnati, who is recovering from a long and serious illness, will spend the winter in the South.——Dr. L. M. McFadden, Staunton, has been elected to the legislature from Fayette County.——Dr. Thomas B. Marquis, Lisbon, is seriously ill with typhoid fever.——Dr. Oscar Berghausen, Cincinnati, has gone to Berlin.——Dr. Alexander J. Erwin and family, Mansfield, have gone to their winter home in Los Angeles.——Dr. William D. Hamilton, Columbus, who was recently operated on for appendicitis, is improving and will soon return home.——Dr. Joseph E. Boylan and daughter, Cincinnati, sailed for Europe December 5.

PENNSYLVANIA.

Hospital Dedicated.—The new Lancaster General Hospital, erected at a cost of $75,000, was dedicated November 30.

New Hospital for Braddock.—Braddock is to have a general hospital. The old Mills homestead has been purchased at a cost of $30,000, and alterations are now under way that will cost about $15,000 more. It is expected that the institution will be ready to receive patients early in the spring. The Braddock Medical Society is a prime mover in the work and is fully represented on the board of directors of the hospital.

Philadelphia.

Medical Society Elects Officers.—At the regular meeting of the University of Pennsylvania Medical Society November 17 the following officers were elected for the ensuing year: President, Dr. David Riesman; vice-presidents, Drs. J. Dutton Steele and J. B. Carnett, and secretary, Dr. John M. Cruice.

Personal.—On December 5 a farewell reception was tendered Dr. Josiah C. McCracken, who will leave for China during this month to establish a medical school which shall represent the University of Pennsylvania in the city of Canton. An address, was made by Prof. Harlan Page Beach of Yale University.——Dr. Robert H. Chase was selected chairman, and Dr. William H. Good, clerk, of the newly organized Northeast Branch of the County Medical Society.

Health Report.—The total number of deaths from all causes reported for the week was 463, as compared with 472 for last week and 426 for the corresponding week of last year. The principal causes of death were: Heart disease, 58; acute respiratory disease, 68; enteritis, 9; appendicitis, 3; Bright's disease, 36; typhoid fever, 12; diphtheria, 18; tuberculosis, 41; cancer, 18; apoplexy, 25; premature birth, 12; suicide, 7; accidents, 14, and marasmus, 8. There were 253 cases of contagious disease, with 31 deaths, as compared with 269 cases and 27 deaths for the previous week. There were 85 new cases of diphtheria, with 19 deaths. This disease has caused the officials of the health department some concern.

TEXAS.

Personal.—Dr. and Mrs. John Grammer, Fort Worth, returned November 20 from a summer in Europe.

Great Gifts to Sanatorium.—On November 17 $90,000 was pledged in thirty-five minutes for the building of the Baptist Memorial Sanatorium, Dallas.

Eighth District Medical Association.—The association for this district held its fourth semi-annual meeting at Bay City November 14 and 15. Dr. James E. Simons, Bay City, was elected president. The next meeting will be held in Cuero, April 4 and 5, 1906.

GENERAL.

Philippine Journal of Science and Other New Papers.—The Bureau of Government Laboratories at Manila will issue a journal in place of the bulletins which have been the method of presenting results of research and experience in the Philippines. It is to be called the *Philippine Journal of Science;* each issue to consist of 112 pages and free use is to be made of illustrations. The scope of the journal will be general, but the medical part will occupy more space than any other department. This proposal indicates that an interesting and valuable journal will be created.——The *Northwestern Lancet* has now become the *Journal of the Minnesota State Medical Association and the Northwestern Lancet* and will be published under the direction of the council of the association. The publication committee consists of Drs. W. S. Fullerton, Thomas McDavitt and F. A. Knights, and the editor is Dr. W. A. Jones. The *Northwestern Lancet* has always published excellent original matter and has maintained a commendable editorial stand. The Minnesota profession deserves praise for completing this arrangement and, with the aid of a united profession, a journal should result more excellent even than has been the past character of the *Northwestern Lancet.*——The *Journal of the New Mexico Medical Association* is presenting a bright appearance. Dr. G. W. Harrison, the editor, and Drs. G. S. McLandress and J. H. Wroth, assistants, are issuing a newsy little monthly.——The *Journal of Physical Therapy* is a new magazine, edited by Dr. G. M. Blech, Chicago, and published by Frank S. Betz, Hammond, Ind. As its name indicates, it will be devoted to radiotherapy and the various mechanical agencies.——The *Central States Medical Monitor* is the result of the consolidation of the *Medical and Surgical Monitor* and the *Central States Medical Magazine.* Dr. Samuel E. Earp, Indianapolis, will be the editor and his salutatory promises an independent, impartial publication for the general practitioner.

Yellow Fever in Cuba.—Passed Assistant Surgeon von Ezdorf reported from Havana, November 20, that all cases at Havana which have been diagnosed as yellow fever are passed on by a board of diagnosis. When a suspicious case is reported the patient is taken to the hospital and the residence fumigated for the purpose of killing mosquitoes. The board of diagnosis is notified and after making careful study of the case, confirms or negatives the diagnosis of yellow fever. All the cases have been traced to what is known as the infected district, which is located in the central portion of the city. Several new cases have been reported and Dr. von Ezdorf states that the situation in Havana is becoming serious. Acting Assistant Surgeon Nunez reports that in view of the prevalence of yellow fever in Havana an active campaign is being organized in Matanzas, by direction of the chief health officer of Cuba, to prevent its possible importation and propagation in that city. Two of the city physicians have been detailed to inspect and to keep a record of all the non-immune passengers arriving from Havana by train, noting their addresses, and reporting to the local health officer their condition, which is ascertained by daily visits for five consecutive days after arrival in the city. The local health officer has recommended organizing a special commission for contagious diseases out of the most prominent practitioners in town, to act in an advisory capacity in the determination of doubtful diagnoses. He also points out the necessity of increasing the mosquito brigade and the force devoted to general sanitation, in order to insure a better service, and hence the probability of its success in averting the propagation of yellow fever in the case of reaching that locality. Precautions will also be observed by the quarantine authorities with all vessels arriving from Havana, particularly those in the coastwise trade, hitherto free from quarantine restrictions, to meet any emergencies that may arise. Non-immune passengers arriving at Santiago by train from Havana are examined by the medical inspectors before they are allowed to leave the cars. The same precautions are observed at Camaguey.

CANADA.

Typhoid Fever in Winnipeg.—The number of typhoid cases in Winnipeg during November was much less than for the same month last year.

Smallpox in Ontario.—Smallpox has appeared at Belleville, Ont., and at another point in Ontario, 15 miles from Sudbury. Toronto has now 15 cases. The disease has also appeared in Queens County, New Brunswick.

Fall Medical Examinations of the Ontario Medical Council.—These examinations were held in Toronto during the week ending December 2. There were 33 candidates in the primary and 45 in the intermediate and final examinations.

Personal.—Dr. William J. Bannister, late of Cork, Ireland, has commenced practice in Winnipeg.——Dr. Harper Wilson, who has been surgeon for the Crow's Nest Pass Coal Company, of Fernie, B. C., has decided to locate in Winnipeg.

Toronto's Vital Statistics for November.—During the month of November just past there were 411 births in Toronto, 328 marriages and 293 deaths. In October the births were 737, but that month the city clerk sent out special notices reminding parents of registration. Apparently there are a great many physicians and parents in Toronto who do not believe in registering births. Of the total number of deaths in the city during November, 58 were due to pneumonia and tuberculosis. Seventy children under one year of age died during November, and fifty persons over 70.

FOREIGN.

Fewer Medical Students in Austria.—In 1895 the degree of doctor of medicine was conferred on 1,011 medical students in the universities of Austria and Hungary. In 1904 only 561 similar degrees were conferred.

Chair of Applied Therapeutics at Paris.—The *Presse Médicale* for November 18 states that the medical faculty of the Paris University has reported favorably on the creation of a professorship of applied therapeutics. The funds for the endowment of the chair were presented by the duc de Loubat.

Plague in Japan.—The American consul at Kobe reports that plague is present in Kobe and in Osaka. A dispatch from Seattle states that the officers of the steamship *Dakota* report that this disease is raging in Yokohama and that probably no more vessels will be given clean bills of health at present.

Austrian Society for Combating Quackery.—A meeting was called at Vienna to found a new society with the title *Gesellschaft zur Bekämpfung des Kurpfuscherthums.* Members of various medical societies attended, as also representatives of the health office, city council and police. Dr. Grün outlined the present status of irregular practitioners' quack practices in Austria, and Dr. Charas described the aims of the new organization. Professor Kassowitz was elected president and Professor Ausserer and Dr. Charas vice-presidents.

Medical Certificate for Chauffeurs in France.—The last *Semaine Médicale* states that the minister of the interior in France appointed a committee representing different government departments to suggest measures to regulate the automobile evil. The committee met in October and its report has been handed in to the authorities who have the matter now under advisement. The report states that the accidents from automobiles are due mainly to the heedlessness or the insufficiency of the chauffeurs. At present there is no age limit, any one can run an automobile, a child of 12, an epileptic or degenerate of any kind. The committee urged the adoption of an age limit, graduating it to the power of the machine. For an automobile of less than 35 horse power, a chauffeur 18 years old might well suffice, but for more powerful machines the lowest age limit should be 21, and the chauffeur must have learned to manage the machine by practicing with less powerful ones at first. The report also urges the adoption of the requirement of a medical certificate to the effect that the candidate for driving an automobile must be sound in mind and body.

In Russia.—The *St. Petersburg med. Wochft.* for November 11 appears somewhat curtailed, "owing to the general strike among the printers." A brief notice states that physicians at many points are joining in the present agitation for freedom. A general meeting of physicians connected with the hospitals of Moscow was held late in October and the following resolution was adopted: "Although the physicians regard the strike as an effectual and the least bloody measure in the struggle for freedom and justice, yet they do not join in the strike, but remain at their posts, prepared to cope with emergencies if there is bloodshed. In order, however, to show that they indorse the general strike, they set aside 20 per cent. of their salaries for a strike fund, under condition that some representatives of the hospital physicians be appointed on the general central strike committee. The administrative authorities of the city and hospitals are hereby warned that any attempt to enforce repressive measures on the physicians of the hospitals will be met with withdrawal of the physicians from their posts, disclaiming all responsibility for the consequences that may ensue."

Cholera in Europe.—The German health authorities are anticipating that there will be another outbreak of cholera in Germany in the spring when the rivermen come through from Russia. A number of new regulations have been announced, among them that lime for disinfection will be supplied from the supervision stations to rivermen and others on the navigable streams, the expense to be borne by the general government. Persons traveling and working along navigable rivers in the cholera district are liable to contract cholera if they drink the water of streams, and, therefore, official arrangements must be made to supply them with good drinking water. The workmen along the river must be inspected daily to see that they have a suitable supply of pure drinking water with them. Supplies of drinking water for vessels navigating these streams must be attended to by the local sanitary authorities of the communities along the rivers, who are the ones most interested in the river traffic and consequently should bear the expense. Special measures are advised for disinfection of the rafts of logs coming through from Russia, as also of those suspicious of cholera. All the articles on the rafts of no value are to be burnt, and the others disinfected. For this purpose a mixture of equal parts of crude carbolic acid and a cheap oil, linseed or petroleum, is recommended.. The mixture is limpid and has a tendency to spread out on the surface of the water, so that it is particularly adapted for disinfecting the stagnant water in the cracks between the logs and also the floor of the raft and suspicious points along the river bank. It is not recommended for disinfection of dry hay or straw, but serves admirably for damp articles.

Student's Number of French Exchange.—The *Progrès Médical* for November 11 is an exceptionally large number, and more than a hundred pages are devoted to data in regard to universities, medical colleges, medical societies, prizes offered and other information of interest to medical students and physicians. The institutions listed include those of all the French-speaking countries, Belgium, Canada and Switzerland, as well as France and the French colonies. It is a valuable reference work for a physician or student intending to visit any of these countries. The journal is published rue des Carmes 14, Paris, Bourneville, the eminent neurologist, being the editor-in-chief, as also of the *Archives de Neurologie.* We learn from this educational number that instruction in oto-rhino-laryngology is not included in the official medical course in France, except at the medical school at Bordeaux, where there is an assistant professor of this specialty, and fourth-year students are required to attend a course of lectures on this subject. Elsewhere instruction in oto-rhino-laryngology is left to private initiative, a few eminent specialists holding private courses and clinics. The country doctor, during his five years' study of medicine, never had occasion to look at a tympanum, a larynx or inferior turbinate, and never used an otoscope, and yet he is consulted for oto-rhino-laryngologic affections perhaps as frequently as any other, and has to treat them as best he can. The signed editorial on the subject urges compulsory instruction in this specialty, remarking that all that need be done is to copy Germany, who, "notwithstanding her ardor for war, does not forget the peaceful conquests of science."

Behring on His Tuberculosis Remedy.—The last *Allg. med. Ct.-Ztg.* cites the Paris *Temps* to the effect that Dr. Bernheim, of Paris, applied at once to von Behring, asking him for some of his new remedy to try it in the Tuberculosis Polyclinic, which has just been founded by the Paris Antituberculosis League. Behring wrote in reply: "My new remedy (*Heilmittel*) can not be sent away without the danger of losing some of its specific properties. I obtain the TX from the animal body in a form which can be likened most appropriately to that of an explosive substance. As soon as the remedy leaves its place of production, that is, the living body, it is exposed to changes which have a great resemblance to coagulation of the blood as soon as the blood flows out of the blood vessels. It is precisely on this account that the control of the curative value of my remedy is possible only at the place of origin and production and only by impartial investigators who have thoroughly learned under my direction the great difficulty and tediousness of the process required for the production of TX. Such precautions are by no means unusual in the testing of new remedies. I remind you only of Pasteur's protective inoculations against hydrophobia, which can not be handed over freely to every clinician, to say nothing of every general practitioner. Besides this, the application of TX is much more difficult and delicate than that of the Pasteur vaccine against hydrophobia. I have more important reasons for refraining fr[illegible] at the mode of production of the TX. I [illegible] of the process for a later occasion, but I may inform you now that I am at present discussing with Metchnikoff the feasibility of producing my TX in the Paris Pasteur Institute, whence its application to the sick can be supervised. Not until the first series of experiments and several months of observation have demonstrated this TX to be usable shall I think of establishing other centers for treatment by my method. All this readily explains why I announced that I should not publish information in regard to my new tuberculosis remedy until after an entire year." (Behring's original communication was given on page 1339.)

Hirschberg's Impressions of America.—Prof. J. Hirschberg has been contributing a series of articles to the *Medizinische Klinik* under the heading, "My Third Trip to America," describing his visit to Portland as the guest of the American Medical Association at its last annual meeting. He remarks in regard to American science, especially ophthalmology, that it has gained by immigration as well as by natural growth, citing the names of several German ophthalmologists now citizens of the United States, while paying a high tribute to the general standing of the specialty and giving a historical sketch of its development in this country. He tells his countrymen that any one stepping into the bubbling spring of American hospitality must have a powerful constitution, an indestructible stomach and a certain equipoise, for he can count on immense distances and unusual demands on his endurance. He was on the special train on July 4, but had sufficient experience of the celebration as the train passed through cities to enable him to appreciate the articles in The Journal of the American Medical Association on the subject. He cites parts of them entire, remarking that they will certainly arouse in his readers the same amazement and horror as in him when he first read them. Another thing which much impressed him was the small number of children in the true American families which he met. He remarks in regard to the American institutions of divorce, lynch and graft that they are part of the children's diseases through which this great and young country is passing. He visited certain important imported scientific libraries, which, he remarks, have been lost to Germany, as the government has no money for such purposes. The Educational Number of The Journal is frequently quoted in his articles, with the comment that Germany has nothing of the kind, although the leading British and French journals publish an annual students' number. He mentions The Journal frequently, describing its phenomenal growth and saying that it deserves the attention of the German reader, which, he adds, "it has already found, as our important medical journals review and abstract its contents regularly." He regards the American Medical Association, "in the maner of its organization and workings, as of the greatest importance for the entire people, as well as for the medical profession, in the United States." The Berlin Docenten-Verein for Vacation Courses has had 16,293 physicians attend its lectures between 1880 and 1894, among them thousands of Americans. He has had hundreds attend his own courses, and his general impression is that in talent they average about the same as the German students, and their industry is satisfactory, but their preliminary training is not quite equal to that of the Germans. In reply to a question as to what he thought of the "exchange of university professors," he remarks that "to date there has been no exchange of peers." In conclusion, he expresses surprise at the long-suffering patience of the American public in allowing the railroads to impose their preposterous lengths of ticket on the travelers. On his return trip he finally laid his ticket aside for a souvenir and paid his fare from city to city rather than handle what he calls "the rattlesnake of the American railroads."

Pharmacology

BIOPLASM.

In our issue for November 18 we graphically showed in these columns that "Bioplasm" and "Sal Lithin," exploited by the Bioplasm Company, of New York, are being advertised directly to the public in a manner that is not usually adopted by an honorable firm, and which in itself shows fraud or at least an attempt to deceive. Our exposé of this Machiavelian method of appealing to the public should be enough to deter any thinking physician from prescribing this nostrum. Since it is advertised in medical journals which make a pretense at decency, one of which is a weekly, we presume it is necessary to give more attention to this product and to show the character of the claims made for it by its exploiters.

ITS COMPOSITION.

The circulars sent out by these people bear evidence of having been written by persons who are either densely ignorant of the subject on which they write or decidedly unscrupulous. A glance at the following quotations taken from these circulars shows very clearly of what a mass of absurdity and contradiction they are composed:

"After a careful extraction under aseptic methods the enzymes are treated by a process which unites them, creating a new product or ferment which resembles closely the bioplasm of Dr. Lionel S. Beals. . . . There is in bioplasm the several enzymes[1] (ferments) of digestion which include nuclein, lecithin, trypsin, etc."

In another circular we are told:

"Bioplasm is produced from the digestive and ductless glandular organs of young herbivorous animals, but it essentially differs from the glandular extracts and nuclein preparations. . . . The defibrinated products after cultivation are desiccated and finally triturated with chemically pure sugar of milk. The exceptional therapeutic virtue of bioplasm is chiefly attributed to the compound element acquired by the process of cultivation described. It positively contains nothing besides the organic products stated, the vegetable ferments being no longer used."

Of course, intelligent physicians know that there is no process by which digestive enzymes may be united, creating a new product of a ferment nature. In the circular we also find this positive statement:

"Bioplasm contains absolutely nothing besides the organic products stated, and its marvelous curative properties reside in the basic ferment resulting from action of the 'mother substance' of the several digestive ferments upon each other."

We learn from another circular:

"Bioplasm . . . non-toxic preparation of animal and vegetable enzymes so compounded as to preserve their original cell vitality."

Note we have just quoted that the vegetable ferments are no longer used, and that only the organs of young herbivorous animals are utilized. The enumeration of nuclein and lecithin as digestive enzymes is sufficient to show that the writer of the circular knows little of the subject on which he has written.

ITS THERAPEUTIC CLAIMS.

The therapeutic claims made for this cure-all are as grotesque and as absurd as are those which are made regarding its composition. It would be wearisome to enumerate all the diseases which it is claimed to cure, but a few taken at random will not be out of place:

"Equally efficient in morbid obesity and emaciation."

"A fatal epidemic of diphtheritic toxemia in West Virginia was checked only when Bioplasm was used."

Here is what appears on the label as it is sold in the drug stores:

"Indications: All neuroses or other disorders in which assimilation and metabolism are faulty. Most prompt and powerful restorer of leucocytes and phagocytes, immunizing by strengthening bactericidal properties of blood. Unique as neuro-nutrient and blood builder, invaluable in Tuberculosis, Typhoid, Scarlet and Malarial Fevers; in Diptheria, Pneumonia, La Grippe, Dysentery, etc.; prompt specific in all forms of indigestion, unequaled in Locomotor Ataxia, in Pelvic diseases of women and convalescence."

It may be interesting for physicians who are prescribing bioplasm to have quoted for their edification some of the testimonials from the laity:

BROMIDROSIS (OFFENSIVE PERSPIRATION).

"'I found relief in a short time after beginning Bioplasm, more noticeable to others than myself. I think it is due to say that, while I was taking it, I used no other remedies.'"

"IMPOTENCE."

"I became incompetent at the age of 45, as a result of a long nervous strain from overwork and unusual responsibility. For four years I have tried many doctors and many remedies, including the rest cure, with some improvement in my general health, but none in my functions. I was gradually drifting towards melancholia, when a physician advised me to try Bioplasm. I did so faithfully, and inside of a week noticed a change in my feelings. My depression disappeared and my ambition returned, and gradually all my powers and functions were restored to me. I used nothing but Bioplasm, except an occasional aperient. In my whole vigorous life I was never better in every way than I am now—and I consider *myself a perfect* man, thanks to Bioplasm. This should be made known to the million sufferers, such as I, and you may use this as you see fit."

"INFANTILE INDIGESTION.

. . . "We had no more trouble with baby after using that sweet powder (Bioplasm), which she took greedily, and the only medicine you have prescribed which we have not had a struggle with her to take. The relief from suspense is great, I assure you." . . . .

A WONDERFUL CURE.

Among the diseases in which Bioplasm seems to get in its work most effectively is tuberculosis, and if one-tenth of what the literature claims for it were true, consumption would soon be a thing of the past. Here is one instance worth recording: A certain physician reported one of the most rapid cures ever effected. His patient had night sweats that were very bad, had been to Colorado, "has taken all patent medicines on the market," his previous physician gave him up and said he could not live through the winter; nine physicians had treated him and given him up, assuring him that his days on earth were few.

This is enough to show that the poor patient was in the very last stage, and yet a miracle was performed, for after giving the Bioplasm for a week the testimonial says:

"The change in my patient during the seven days of treatment is most remarkable. The night sweats have ceased. The appetite has improved, and the condition of the lungs has improved to such an extent as to make me sanguine where I have been utterly hopeless. . . Doctor, I feel like a new man. My strength is rapidly returning, and all I want now is a little more time and Bioplasm, and Bio will put me on a sound basis for the enjoyment of life, and a happy old age—a living chagrin to the many physicians who have been pointing me to the grave."

But there is another side to this bright picture. Before us is correspondence to the effect that the patient died soon after this testimonial was written. The doctor who reported the remarkable cure had been in practice but a little while. He evidently imposed on himself, and in a recent letter he expresses regret that he wrote as he did. It is for this reason that we omit his name. In a letter recently received he says:

"Yes, I have used Bioplasm a number of times since with absolutely no results. . . . I was very enthusiastic at that time and it is certain that I would not attach such value to the treatment as at the time mentioned. When I wrote to the Bioplasm people, it was simply with the hope that their product might be of value to those afflicted with tuberculosis."

LOCOMOTOR ATAXICS CURED.

The following letter, from one whom we will call X, as we do not care, under the circumstances, to publish his name, is one of the bits of literature that is doing good work for Bioplasm:

———, June 8, 1905.

Bioplasm Company, 100 William Street, New York City:

Gentlemen:—Your inquiry about Mr. R——, the tabetic patient from Mexico, who has been taking Bioplasm for some seven or eight months, I want to answer briefly, so as to cover the ground.

Mr. R—— is about 45 years old, rather frail all his life. . . . Something less than a year ago he began to experience trouble with his legs and general health, . . . and on consultation with doctors was promptly pronounced a tabetic, having almost all the classical symptoms. His people here came to me, asking what to do. I could only advise Bioplasm. This was begun as soon as he could get a supply from you, in the meantime being treated with strychnin, massage, and so forth, ... No improvement. Soon after beginning Bio, felt better. Five or six months ago he came here. When he arrived he could not get on a street car. To see him walk was agony. Soon he was taken to the cars with an attendant. Shortly after he was going around alone. Took long walks. Got better every day. He called on me yesterday, and upon inquiry, said: "The padded sensation of soles still present to some degree, and knee-jerk absent. Aside from these, I consider myself a well man." He looks well, feels well, walks well, and as far as can be told, IS well.

Could all ataxics see this case as I have seen it, they would send in such a blast for Bio that you would flee from it. Doubtless, "things seen are mightier than things heard" (of), and there are so many "cures" reported, that, like miracles, dwindle at short range, that one more or less will not count for much—in print. But I have seen this, and I believe.

Since coming here, Mr. R—— has taken Bio constantly, and also has had massage twice a week. No other treatment, except that he has been going through some of the kicking for "re-education."

Yours very truly, ——— M.D.

A physician in Kansas wrote to the Bioplasm people, asking them to give him the names of some reputable and well-known physicians who had used Bioplasm with the success that was claimed for it. In reply the Bioplasm people said:

"We take pleasure in referring you to Dr. X, whose letter we enclose herewith (see above), and who is well known and highly esteemed in ——."

We had already written for information in regard to Dr.

---

[1] We quote spelling and grammar exactly in all these extracts.

X and received a reply to the effect that no such physician was practicing in ———. On receiving the communication from our Kansas correspondent we again tried to get information in regard to Dr. X, which resulted in the following letter just received from our investigator:

> In regard to Dr. X, of whom you wrote me a few days since: He graduated from ——— years ago; he suffers from locomotor ataxia, and can only get around in a wheel chair; he is a deaf mute, and has been in that condition for ten years; he has not practiced any for twelve years; he has no license in this state or county. He uses Bioplasm himself, and thinks he derives benefit from it. He says that he only recommends it from his personal experience. Dr. C. is his attending physician and has charge of him in a general way. Dr. C. says that he is a perfectly innocent, well-meaning, broken down man.

We have followed up several other testimonials and it would make interesting reading if we had space to devote to a record of the results of the investigation.

One physician from Pennsylvania writes:

> "I am glad that Bioplasm is finally being exposed. About two years ago, the Bioplasm people imposed on we younger physicians by giving us testimonials and ending with selling us five bottles of their dollar size for $2.50. I dispensed an entire bottle with no effect whatever in any of its so-called usages. The other four I have still as a reminder of my folly. A few days ago a 'locomotor ataxic' told me of his wonderful new cure or 'sure cure' and behold it was Bioplasm which he got direct from the firm with their wonderful 'epitome.' He had just run out of his '175 tablets for $1.50,' and wanted to get some more."

When some great disaster overtakes a community and the dead and dying lie scattered about, fiendish ghouls steal forth to despoil the dead and the helpless. By common consent such loathsome creatures are usually ordered shot when found at such work; but with what words can we characterize those still more loathsome creatures who scent quarry in that vast army of the sick and miserable, who, loath to acknowledge the presence or approach of the king of terrors, turn to those who speak them fair with bright promises of succor while they rob them of a few dollars and, far worse, ofttimes of the one chance of help which medical science affords? And what shall be said of physicians who, consciously or unconsciously, aid in such a despicable business?

THE SUBTLE POISONS.

BY SAMUEL HOPKINS ADAMS.

Under the above title Mr. Adams, in *Collier's Weekly*, December 2, exposes some of the nostrums that contain acetanilid, morphin, cocain, etc., but the acetanilid group receives the greatest attention. At the head of the article are given the names of twenty-two persons who have died from acetanilid poisoning, as reported by the newspapers. The article, as were the others, is illustrated. We quote the following interesting portions:

"Ignorance and credulous hope make the market for most proprietary remedies. Intelligent people are not given largely to the use of the glaringly advertised cure-alls, such as Liquozone or Peruna. Nostrums there are, however, which reach the thinking classes as well as the readily gulled. Depending, as they do, for their success upon the lure of some subtle drug concealed under a trademark name, or some opiate not readily obtainable under its own label, these are the most dangerous of all quack medicines, not only in their immediate effect, but because they create enslaving appetites, sometimes obscure and difficult of treatment, most often tragically obvious. Of these concealed drugs the headache powders are the most widely used, and of the headache powders Orangeine is the most conspicuous.

Orangeine.

"Orangeine prints its formula. It is, therefore, its proprietors claim, not a secret remedy. But to all intents and purposes it *is* secret, because to the uninformed public the vitally important word 'acetanilid' in the formula means little or nothing. Worse than its secrecy is its policy of careful and dangerous deception. Orangeine, like practically all the headache powders, is simply a *mixture* of acetanilid with less potent drugs. Of course, there is no *orange* in it, except the orange hue of the boxes and wrappers which is its advertising symbol. But this is an unimportant deception. The wickedness of the fraud lies in this: That whereas the nostrum, by virtue of its acetanilid content, thins the blood, depresses the heart, and finally undermines the whole system, it claims *to strengthen the heart and to produce better blood*. Thus far in the patent medicine field I have not encountered so direct and specific an inversion of the true facts.

"Last July an 18-year-old Philadelphia girl got a box of Orangeine powders at a drug store, having been told that they would cure headache. There was nothing on the label or in the printed matter inclosed with the preparation warning her of the dangerous character of the nostrum. Following the printed advice, she took two powders. In three hours she was dead. Coroner Dugan's verdict follows:

"'Mary A. Bispels came to her death from kidney and heart disease, aggravated by poisoning by acetanilid taken in Orangeine headache powders.'

Prescribing Without Authority.

"Yet this poison is being recommended every day by people who know nothing of it and nothing of the susceptibility of the friends to whom they advocate it. For example, here is a testimonial from the Orangeine booklet:

"'Miss A. A. Phillips, 66 Powers street, Brooklyn, writes: "I always keep Orangeine in my desk at school, and through its frequent applications to the sick I am called both 'doctor and magician."'

"If the school herein referred to is a public school, the matter is one for the Board of Education; if a private school, for the Health Department or the County Medical Society. That a school teacher should be allowed to continue giving, however well-meaning her foolhardiness may be, a harmful and possibly fatal dose to the children intrusted to her care, seems rather a significant commentary on the quality of watchfulness in certain institutions.

"Obscurity as to the real nature of the drug, fostered by careful deception, is the safeguard of the acetanilid vender. Were its perilous quality known, the headache powder would hardly be so widely used. And were the even more important fact that the use of these powders becomes a habit, akin to the opium or cocain habits, understood by the public, the repeated sales which are the basis of Orangeine's prosperity would undoubtedly be greatly cut down. Orangeine fulfills the *prime requisite of a patent medicine in being a good* 'repeater.' Did it not foster its own demand in the form of a persistent craving, it would hardly be profitable. Its advertising invites to the formation of an addiction to the drug. 'Get the habit,' it might logically advertise, *in imitation* of a certain prominent exploitation along legitimate lines. Not only is its value as a cure for nervousness and headaches insisted on, but its prospective dupes are advised to take this powerful drug as a *bracer*. . . .

"Where I have found a renegade physician making his millions out of Peruna, or a professional promoter trading in the charlatanry of Liquozone, it has seemed superfluous to comment on the personality of the men. They are what their business connotes. With Orangeine the case is somewhat different. Its proprietors are men of standing in other and reputable spheres of activity. Charles L. Bartlett, its president, is a graduate of Yale University and a man of some prominence in its alumni affairs. Orangeine is a side issue with him. Professionally he is the Western representative of Ivory Soap, one of the heaviest of legitimate advertisers, and he doubtless learned from this the value of skillful exploitation. Next to Mr. Bartlett, the largest owner of stock (unless he has recently sold out) is William Gillette, the actor, whose enthusiastic indorsement of the powders is known in a personal sense to the profession which he follows, and in print to hundreds of thousands of theater-goers who have read it in their programs. Whatever these gentlemen may think of their product (and I understand that, incredible as it may seem, both of them are constant users of it), the methods by which it is sold, and the essential and mendacious concealment of its real nature, illustrate the level to which otherwise upright and decent men are brought by a business which can not profitably include either uprightness or decency in its methods.

"Orangeine is less dangerous, except in extent of use, than many other acetanilid mixtures which are much the same thing under a different name. A friend of mine with a weak heart took the printed dose of Laxative Bromo Quinin and lay at the point of death for a week. . . .

Dangers of Antikamnia.

"In the 'ethical' field the harm done by this class of proprietaries is perhaps as great as in the open field, for many of those which are supposed to be sold only in prescriptions are as freely distributed to the laity as Peruna. And their advertising is hardly different.

"Antikamnia, claiming to be an 'ethical' remedy, and advertising through the medical press by methods that would, with little alteration, fit any patent pain-killer on the market, is no less dangerous or fraudulent than the Orangeine class which it almost exactly parallels in composition. It was at first exploited as a 'new synthetical coal-tar derivative,' which it isn't and never was. It is simply half or more acetanilid (some analyses show as high as 68 per cent.) with other unimportant ingredients in varying proportions. In a booklet entitled 'Light on Pain,' and distributed on doorsteps, I find under an alphabetical list of diseases this invitation to form the Antikamnia habit:

"'Nervousness (overwork and excesses)—Dose: One Antikamnia tablet every two or three hours.

"'Shoppers' or Sightseers' Headache—Dose: Two Antikamnia tablets every three hours.

"'Worry (nervousness: "the blues")—Dose: One or two Antikamnia and Codein tablets every three hours.'

"Codein is obtained from opium. The codein habit is well known to all institutions which treat drug addictions, and is recognized as being no less difficult to cure than the morphin habit.

"A typical instance of what Antikamnia will do for its users is that of a Pennsylvania merchant, 50 years old, who had declined, without apparent cause, from 140 to 116 pounds, and was finally brought to Philadelphia in a state of stupor. His pulse was barely perceptible, his skin dusky and his blood of a deep chocolate color. On reviving he was questioned as to whether he had been taking headache powders. He had, for several years. What kind? Antikamnia; sometimes in the plain tablets, at other times Antikamnia with codein. How many? About twelve a day. He was greatly surprised to learn that this habit was responsible for his condition.

"'My doctor gave it to me for insomnia,' he said, and it appeared that the patient had never even been warned of the dangerous character of the drug.

"Were it obtainable I would print here the full name and address of that attending physician, as one unfit, either through ignorance or carelessness, to practice his profession. And there would be other physicians all over the country who would, under that description, suffer the same indictment within their own minds for starting innocent patients on a destructive and sometimes fatal course. For it is the careless or conscienceless physician who gets the customer for the 'ethical' headache remedies, and the customer, once secured, pays a profit, very literally, with his own blood. Once having taken Antikamnia, the layman, unless informed as to its true nature, will often return to the drug store and purchase it, with the impression that it is a specific drug, like quinin or potassium chlorate, instead of a disguised poison, exploited and sold under patent rights by a private concern. The United States postoffice, in its broad tolerance, permits the Antikamnia company to send through the mails little sample boxes containing tablets enough to kill an ordinary man, and these samples are sent not only to physicians, as is the rule with ethical remedies, but to lawyers, business men, 'brain workers' and other prospective purchasing classes. The box bears the lying statements: 'No drug habit—no heart effect.'

"Just as this is going to press the following significant case comes in from Iowa:

"'FARMINGTON, IOWA, October 6.—(Special to the *Constitution-Democrat.*) Mrs. Hattie Kick, one of the best and most prominent ladies of Farmington, died rather suddenly Wednesday morning at 10 o'clock from an overdose of Antikamnia, which she took for a severe headache from which she was suffering. Mrs. Kick was subject to severe headaches and was a frequent user of Antikamnia, her favorite remedy for this ailment.'

"There is but one safeguard in the use of these remedies: to regard them as one would regard opium and to employ them only with the consent of a physician who understands their true nature. Acetanilid has its uses, but not as a generic pain-killer. Pain is a symptom; you can drug it away temporarily, but it will return, clamoring for more payment until the final price is hopeless enslavement. Were the skull and bones on every box of this class of poison the danger would be greatly minimized.

"With opium and cocain the case is different. The very words are danger signals. Legal restrictions safeguard the public, to a greater or less degree, from their indiscriminate use. Normal people do not knowingly take opium, or its derivatives, except with the sanction of a physician, and there is even spreading abroad a belief (surely an expression of the primal law of self-preservation) that the licensed practitioner leans too readily toward the convenient narcotics.

"But this perilous stuff is the ideal basis for a patent medicine, because its results are immediate (though never permanent), and it is its own best advertisement in that one dose imperatively calls for another. Therefore it behooves the manufacturer of opiates to disguise the use of the drug. This he does in various forms, and he has found his greatest success in the 'cough and consumption cures' and the soothing syrup class. The former of these will be considered in another article. As to the 'soothing syrups,' designed for the drugging of helpless infants, even the trade does not know how many have risen, made their base profit and subsided. A few survive, probably less harmful than the abandoned ones, on the average, so that by taking the conspicuous survivors as a type I am at least doing no injustice to the class. . . .

"Making cocain fiends is another profitable enterprise. Catarrh powders are the medium. A decent druggist will not sell cocain as such, steadily, to any customer, except upon prescription, but most druggists find salve for their consciences in the fact that the subtle and terrible drug is in the form of somebody's sure cure. There is need to say nothing of the effects of cocain, other than that it is destructive to mind and body alike, and appalling in its breaking down of all moral restraint. Yet in New York City it is distributed in 'samples' at ferries and railway stations. You may see the empty boxes and the instructive labels littering the gutters of Broadway any Saturday night, when the drug store trade is briskest.

"Birney's Catarrhal Powder, Dr. Cloe's Catarrh Cure, Dr. Gray's Catarrh Powder and Crown Catarrh Powder are the ones most in demand. All of them are cocain; the other ingredients are unimportant—perhaps even superfluous.

"Whether or not the bottles are labeled with the amount of cocain makes little difference. The habitués know. In one respect, however, the labels help them by giving information as to which nostrum is the most heavily drugged.

"'People come in here,' a New York City druggist tells me, 'ask what catarrh powders we've got, read the labels and pick out the one that's got the most cocain. When I see a customer comparing labels I know she's a fiend.'

"Naturally these owners and exploiters of these mixtures claim that the small amount of cocain contained is harmless. For instance, the 'Crown Cure,' admitting 2½ per cent., says:

"'Of course, this is a very small and harmless amount. Cocain is now considered to be the most valuable addition to modern medicine. . . . It is the most perfect relief known.'

"Birney's Catarrh Cure runs as high as 4 per cent., and can produce testimonials vouching for its harmlessness."

Association News

NEW MEMBERS.

List of new members of the American Medical Association for the month of November, 1905:

ALABAMA.

Hale, R. E., Bellamy.
Sims, A. G., Renfroe.

ARIZONA.

Dameron, L. D., Phoenix.
Fales, W. H., Clifton.

ARKANSAS.

Daniel, S. G., Marshall.
Davis, J. H., Falcon.
Jackson, N. H., Pontoon.
Winegar, E. F., Hot Springs.

CALIFORNIA.

Artiques, J. E., San Francisco.
Fairchild, F. R., San Francisco.
Gross, L., San Francisco.
Weddle, C., Dinuba.
White, J. L., Sacramento.
Yerxa, C. W., Los Angeles.

COLORADO.

Moore, W. M., La Junta.
Peairs, J, E., Pueblo.
St. Clair, R., Cripple Creek.

CONNECTICUT.

Barrows, B. S., Hartford.
Buel, J. L., Litchfield.
Bunce, P. D., Hartford.
Gompertz, L. M., New Haven.
Graves, C. B., New London.
Huntington, S. H., Norwalk.
Jones, L. P., Greenwich.
Judson, W., New Haven.
Klein, A. W., Greenwich.
Leverty, C. J., Bridgeport.
Murphy, M. D., Middletown.
Nettleton, I. L., Bridgeport.
Pomeroy, N. A., Waterbury.
Robbins, G. O., Waterbury.
Ryan, P. J., Hartford.
Sherer, H. C., South Norwalk.
Tenney, A. J., Branford.
Winchell, A. E., New Haven.

DISTRICT OF COLUMBIA.

Keyser, C. S., Washington.
Ransdell, R. C., Washington.

FLORIDA.

Finlay, D. H., Pine Barren.
Fitts, T. B., West Tampa.
Freeman, J. V., Jacksonville.
Hutchings, G., Eustis.
Lowry, R. A., Brooksville.
Thomason, F. G., Kissimmee.

GEORGIA.

Phillips, F. H., Harlem.

IDAHO.

Plumer, J. J., Hailey.
Sears, C. E., Wallace.

ILLINOIS.

Arnold, W. J., Chicago.
Avery, W. M., Compton.
Brinckerhoff, C. E., Chicago.
Blackstone, G. R., Table Grove.
Bell, W. H., Decatur.
Cates, E. M., Wayne City.
Clark, E. E., Danville.
DeBoer, H., Chicago.
Dinsmore, V., Jacksonville.
Duncan, W. P., Jacksonville.
Feltmann, A. W., Chicago.
Francis, C. H., Chicago.
Flint, O. J., Princeton.
Fry, C. B., Mattoon.
Garraghan, E. F., Chicago.
Glenn, J. A., Ashland.
Glenn, F. L., Chicago.
Hemml, S. A., Chicago.
Hilliard, D. A., Jeffersonville.
Jones, T. A., Ridgway.
Kern, N. H., Thawville.
Kirk, J. W., Oblong.
Lyles, A. R., Virginia.
Martin, L., Chicago.
Morrill, C. M., Havana.
Perkins, T. L., Springfield.
Sale, L. O., Fisher.
Sims, S. N., Danville.
Tucker, H. S., Chicago.
Thornton, W. T., Chicago.
Way, J. P., Chicago.
Wild, T., Chicago.

INDIANA.

Clapper, M. M., Hartford City.
Cummins, S. M., Elkhart.
Greene, J. B., Mishawaka.
Hunt, L. F., Anderson.
Johnson, L., Bourbon.
Kistner, J. W., Elkhart.
Letherman, A. P., Valparaiso.
Rennoe, C. A., South Bend.
Robinson, C. C., Indiana Harbor.

IOWA.

Coleman, F. J., Everly.
Sargeant, F. L., Marion.
Wiley, E. D., Des Moines.

KANSAS.

Marriages

S. A. Savitz, M.D., to Miss Sallie Ost, both of Philadelphia, recently.

Scott T. Petrie, M.D., to Mrs. Mathilda Good, both of Chicago, September.

C. Edmund Lerch, M.D., Bernville, Pa., to Miss Jennie Wagner of Robesonia, Pa.

Richard W. Dake, M.D., to Miss Julia Dudley, both of Nashville, Tenn., November 21.

Foster Sudler, M.D., to Miss Elsie L. George, both of Sudlerville, Md., November 29.

Claude B. Cross, M.D., to Miss Bessie A. Taylor, both of Mineral, Kan., November 22.

Francis J. Wilson, M.D., to Miss Anna May Regan, both of Milwaukee, Wis., November 22.

Sol Weir Newmayer, M.D., to Miss Rietta Ulman Hirsh, both of Philadelphia, November 30.

Orville Everette Beebe, M.D., to Miss Mary Edna Wright of Bellingham, Wash., November 29.

Charles E. Glynn, M.D., Davenport, Iowa, to Miss Blanche Langan of Clinton, Iowa, November 22.

Anthony J. Schmit, M.D., Beloit, Wis., to Miss Elsie M. Winkley of Clinton, Wis., November 22.

Lewis F. Zachary, M.D., Byrdstown, Tenn., to Miss Laura Kimes of Monterey, Tenn., November 21.

Thomas Meares Green, M.D., to Miss Emma Perrin West, both of Wilmington, N. C., November 16.

John C. Beauchamp, M.D., Williamson, Ga., to Mrs. Virginia Kenney of Concord, Ga., November 29.

Hiram L. Throgmorton, M.D., Pocahontas, Ark., to Miss Vida Butler of Grapevine, Ark., November 18.

Raleigh A. Buckmaster, M.D., Brandon, Iowa, to Miss Grace A. Jeffers of Cedar Falls, Iowa, November 30.

Harry Gibbons Utley, M.D., Apex, N. C., to Miss Florence Jennings Percival, at Baltimore, November 25.

Philemon Smith Lansdale, M.D., Damascus, Md., to Miss Annie Pyle, at Charlottesville, Va., November 29.

Walter Jameson, M.D., Roanoke, Va., to Miss Frances Virginia Chalmers, at Lynchburg, Va., November 29.

Edward Thomas Anderson, M.D., Platte, S. D., to Miss Julia Edith Orvis of Dubuque, Iowa, November 28.

George Boardman Edwards, M.D., Darlington, S. C., to Miss Marie A. McCullough, at Nashville, Tenn., November 29.

Christian Augustus Dannaker, M.D., Kansas City, Mo., to Miss Mary Beckett Moss of Pawnee City, Neb., November 30.

Samuel J. Gardner, M.D., San Francisco, Cal., to Miss Elizabeth Smith of Sterling, Scotland, at San Francisco, December 6.

Deaths

Edward A. Cobleigh, M.D. Atlanta (Ga.) Medical College, 1872; A.M., LL.D.; one of the founders and dean of the Chattanooga Medical College (Medical Department of Grant University), Chattanooga; professor of the principles and practice of medicine, dermatology and clinical medicine, and lecturer on physical diagnosis at the same institution since 1889; chief of staff at Erlanger Hospital, Chattanooga; member of the Chattanooga and Hamilton County Medical Society, Tennessee State Medical Association, Tri-state Medical Society of Alabama, Georgia and Tennessee, American Public Health Association and American Medical Association; for nine years physician of McMinn County, Tenn.; for one year secretary of the Chattanooga Board of Health, and for four years member of the local board of pension examiners, died at Erlanger Hospital, Chattanooga, November 29, after a short illness, from a complication of diseases. He had practiced in Chattanooga since 1887, and made a success by indefatigable study, untiring activity and a natural adaptability for his vocation. Resolutions of respect were adopted by the faculty of the Chattanooga Medical College, the student classes of the college and the Chattanooga and Hamilton County Medical Society.

Ambrose Loomis Ranney, M.D. New York University, New York City, 1870; a member of the New York County Medical Society, Neurological Society of New York, and once president of the New York Academy of Medicine; formerly adjunct professor of anatomy, New York University, New York City, and professor of nervous and mental diseases in the University of Vermont Medical Department, Burlington; author of "Essentials of Anatomy," "Applied Anatomy of the Nervous System," "Treatise on Surgical Diagnosis," "Practical Medical Anatomy," and many smaller contributions to the medical literature, died suddenly in New York City, December 1, from heart disease, aged 57.

John B. Sterley, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1857; a member of the American Medical Association; surgeon of the One Hundred and Sixty-seventh Pennsylvania Volunteer Infantry, and later district examining surgeon, during the Civil War; a member of the state, county and local medical societies; one of the best-known physicians of Reading, Pa., died at his home in that city, from septicemia due to a carbuncle, after an illness of six months, November 24, aged 69.

William H. Bartran, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1865; a veteran of the Civil War; formerly mayor and superintendent of schools of Fort Howard, Wis.; member of the legislature in 1873 and 1874; physician of Brown County and Green Bay for twelve years; a charter member of Brown County Medical Society, died at his home in Green Bay, November 22, from paralysis, after a long illness, aged 67.

J. Ernest Meiere, M.D. New York University, New York City, 1869; contract surgeon United States Army at the outbreak of the Civil War, but thereafter a surgeon in the Confederate service; appointed consul to Amoy, China, in 1886; city physician of Leadville, Colo., in 1879 and 1880; some-time president of the Lake County (Colo.) and Cripple Creek Medical societies, died at his home in Cripple Creek, December 1, from pneumonia, aged 75.

James N. Reece, M.D. Rush Medical College, Chicago, 1888; in 1898 representative from St. Joseph County in the legislature; local surgeon of the Wabash Railroad; for many years president of the board of education of North Liberty, Ind., died at his home in that place, November 18, after a prolonged illness, from tuberculosis of the bones, aged 49.

Benjamin Myers, M.D. Jefferson Medical College, Philadelphia, 1869; representative in the Ohio legislature from Ashland County from 1874 to 1877; twice probate judge of Ashland County; once mayor of Ashland; a veteran of the Civil War, died from pneumonia at his home in Ashland, November 21, after an illness of a few days, aged 67.

James A. Smeallie, M.D. Albany (N. Y.) Medical College, 1879; formerly of Duluth, Minn.; a member of the Minnesota State Medical Society, Inter-urban Academy of Medicine and St. Louis County Medical Society, died at his home in Cass Lake, Minn., November 25, from tuberculosis, after a long illness.

Joseph Warren Hayward, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1864; surgeon in the federal service during the Civil War, and later surgeon of the Third Infantry, M. V. M., died at his home in Taunton, Mass., November 21, after a lingering illness, aged 64.

Frank Weeks Blair, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1899, of Farmingham N. H.; physician of Strafford County, died at the Cottage Hospital, Portsmouth, N. H., from carcinoma of the stomach, after a long illness, aged 31.

John Samuel Angle, M.D. Jefferson Medical College, Philadelphia, 1862; a surgeon during the Civil War, and for many years local surgeon of the Pennsylvania System, died at his home in Strafford, Pa., November 15, after a prolonged illness, aged 64.

Edmund Bennett, M.D. Jefferson Medical College, Philadelphia, 1855; a member of the Ocean County board of freeholders since 1878, and for many years a director of the board, died at his home in Barnegat, N. J., November 23, from heart disease.

Charles H. Jacobs, M.D. Medical Department of Adelbert College of Western Reserve University, Cleveland, 1883, of Youngsville, Pa., died November 24 at the Emergency Hospital, Warren, Pa., a day after an operation for appendicitis, aged 49.

Joseph B. Davis, M.D. Missouri Medical College, St. Louis, 1883; of Marshall, Mo.,; a member of the Saline County Medical Society, died from nephritis at Excelsior Springs, Mo., November 24, after a long illness, aged 62.

Martha A. Anderson, M.D. College of Physicians and Surgeons, Boston, 1887; formerly a missionary in India, and then a practitioner of Boston and Philadelphia, died at her home in Shelburne, Mass., November 23, aged 62.

Frank H. Hopkins, M.D. Harvard University Medical School, Boston, 1903, of South Boston, Mass., died at Antrim, N. H., November 17, after a long illness, from typhoid fever complicated with pneumonia.

B. H. Lemon, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1885; coroner for the counties of Lincoln and Welland, Ont., was found dead in bed at his home in Thorold, November 28.

Thomas B. Robison, M.D. Medical College of Ohio, Cincinnati, 1891, formerly of Rossville, Ind., died from tuberculosis at Denver, Colo., November 19, after an illness of several years, aged 38.

Salmon B. Sayre, M.D. University of Wooster Medical Department, Cleveland, 1890, died suddenly in his office at Oelwein, Iowa, November 27, from heart disease, aged 36.

Calvin J. Sharp, M.D. San Francisco, 1889, of Rockford, Iowa, died in the Cherokee State Hospital from cerebral hemorrhage, November 14, after an illness of two months, aged 46.

Asabel G. Hopkins, M.D. Cincinnati, 1877, a veteran of the Civil War, died at his home in Muskegon, Mich., November 22, after a lingering illness, from senile debility, aged 86.

Thomas H. Butler, M.D. Hospital College of Medicine, Louisville, 1898, of Monticello, Miss., was shot and instantly killed in his office by Mrs. James F. Birdsong, November 25.

Alphonse Gladu, M.D. University of the Victoria College, Coburg, Ont., 1867, died suddenly at his home in Lafayette, La., November 20, from cerebral hemorrhage, aged 60.

George O. Caldwell, M.D. New York University, New York City, 1886, of Scranton, Pa., died suddenly in the railway station at Manchester, N. H., November 18, aged 45.

Charles H. Barbour, M.D. University of Vermont Medical Department, Burlington, 1874, died at his home in North Clarendon, Rutland County, Vt., November 21, aged 56.

Kate L. S. Sterling, M.D. Women's Medical College, Philadelphia, 1886, a member of the New York County Medical Society, died at New York Hospital, December 1.

William S. Cardwell, M.D. University of Nashville (Tenn.) Medical Department, 1859, died at his home in Prospect, Tenn., November 26, after an illness of two weeks.

William M. Gwynn, M.D. Pennsylvania, 1868, died at his home in Auburn, N. Y., November 21, from pneumonia, after an illness of four days, aged 71.

John William Green, M.D. Rush Medical College, Chicago, 1889, died at his home in Lacey, Iowa, November 21, from uremia, after a short illness.

Milton Welsh Warfield, M.D. Jefferson Medical College, Philadelphia, 1850, died at his home near Lisbon, Howard County, Md., November 26, aged 78.

Albert Philips Hallowell, M.D. Pennsylvania, 1900, died suddenly at his home in Ashbourne, Pa., from heart disease, November 26, aged 28.

Thomas B. Tandy, M.D. Louisville (Ky.) Medical College, 1876, died at his home in Winfield, Kan., November 24, from nephritis.

J. T. Bennett, M.D. 1855, died at his home in Brookville, Pa., November 15, from dropsy, after an illness of two years, aged 83.

Emma DeL. Burd, M.D. New Jersey, 1880, died at her home in Yonkers, N. Y., November 22, after a short illness, aged 61.

Bennett Downes, M.D. Jefferson Medical College, Philadelphia, 1873, died at his home in Frederica, Del., November 25.

Levi Wood, M.D. Albany (N. Y.) Medical College, 1865, died at his home in Ephratah, N. Y., November 28, aged 62.

George H. Gilson, M.D. St. Louis Medical College, 1876, died at his home in Raymond, Ill., November 17, aged 58.

Queries and Minor Notes

HAS TETANUS FOLLOWED QUININ OR MORPHIN HYPODERMICS?

Dr. E. F. McCampbell, Madison, Wis., desires to know if any practitioner knows of a case of tetanus resulting from the hypodermic injection of either quinin or morphin under supposedly aseptic precautions.

CONFIDENTIAL CORRESPONDENCE.

A correspondent has sent us the letter which we reproduce below, which was received at the institution with which he is connected—a reputable sanitarium. It illustrates the methods used by certain unscrupulous individuals and firms handling patent medicines and who advertise that "all correspondence is strictly confidential":

"*Dear Sir*: I have about 1,500 names of users of morphin, cocain, opium, etc., and they are all names taken from letters of inquiries and are all *bona fide* and of recent compilation.

If you can use these names at one cent a name, I would be glad to take the matter up with you.

Thanking you in advance for an answer, I am, ———."

CONTRACT PRACTICE.

Dallas, Texas, Nov. 17, 1905.

To the Editor:—Kindly inform me through The Journal: 1. If it is unethical to belong to a medical club which does the medical practice of its members for stipulated monthly or weekly fees. 2. Whether it is unethical to make visits to members of the club for less than the regular fees, if the physician making the visits does not belong to the club and if the visits are made to poor people who are unable to pay regular fees. A. D. Ferguson, M.D.

Answer.—The general principles underlying club practice have frequently been discussed in The Journal. As a general proposition the profession views club practice as inimical to its best interests, and ultimately unsatisfactory to the public. In particular instances like the one submitted above it is entirely within the province of the local society to decide whether the special proposition is or is not compatible with ethical standards, and subservient to the interest of layman and physician. If possible the full facts should be presented to the society, for its action thereon in any event will determine whether a member may serve the club and also remain in good standing.

The second query involves several different points so that no one answer can be given. Fees should not be cut, except for the poor. For an outside physician to attempt to underbid the club fees in order to get some of the work is unwise, though, perhaps, not flagrantly unethical. That is not the way to meet the evils of club practice. This second problem also should be thoroughly thrashed out in the society. Get every educated reputable physician into the society and agree on fundamental points and then exterminate the quacks.

FOURTH DISEASE.

Minden, Neb., Nov. 21, 1905.

To the Editor:—I would like to know through The Journal the latest ideas concerning "Filatow-Dukesche Krankheit," or fourth disease in regard to its relation to scarlet fever, also where I can obtain the latest and most authoritative works on the subject.

J. R. McKirahan.

Answer.—"Fourth disease" is the name given by Clement Dukes to a series of cases described by him in the *Lancet*, 1900, vol. ii, 1889, cases which resembled in their clinical manifestations either rubella or scarlet fever. A similar set of cases was described by Filatow in 1885, hence the name sometimes applied to this clinical picture, "Filatow-Dukesche Krankheit." The weight of opinion, however, seems to be that the clinical picture described by these writers does not constitute a disease *sui generis*, but that the cases described are either rubella or mild scarlet fever. The verdict seems to be "not proven." A recent discussion of the subject appeared in *La Semaine Médicale*, March 29, 1905, by Cheinisse, in which the literature is also reviewed. The following authors also have written on the subject: Griffith: *Phila. Med. Journal*, 1902, vol. ix, p. 659. Ker: *Practitioner*, 1902, vol. lxviii, p. 139. Dillingham: *American Medicine*, 1903, vol. vi, p. 263. von Bokay: *Deutsch. med. Wochft.*, Oct. 20, 1904. Shaw: *American Jour. Med. Sciences*, January, 1905. Filatow's book on pediatrics is published by the Cleveland Press, 346 Ogden Ave., Chicago. The weight of medical opinion, as stated above seems to be against Dukes' view. Until we know more about the bacteriology of scarlet fever and rubella, however, it is difficult to see how the question can be definitely settled. Meanwhile it would seem safer to regard those cases of the so-called "Fourth Disease" which resemble scarlet fever, as actual cases of the latter and treat them as such, especially as far as isolation is concerned. If they really are cases of scarlet fever, what is a mild infection in one child may give rise to an exceedingly severe infection in another child.

SCOPOLAMIN-MORPHIN ANESTHESIA.

Juda, Wis., Dec. 4, 1905.

To the Editor:—Can you inform me by whom scopolamin is manufactured and where it can be obtained? I fail to find it in any of the drug stores here. H. B. Gifford, M.D.

Answer.—Scopolamin is not a new drug, it has been used to a certain extent for several years. It was first isolated as an alkaloid of scopola, hence the name. According to the eighth decennial revision of the United States Pharmacopeia, scopolamin hydrobromid is the hydrobromid of an alkaloid obtained from plants of the *Solanaceæ*, and is chemically identical with hyoscin hydrobromid. It occurs in crystals. It is a sedative, and as a mydriatic its action is somewhat similar to that of atropin, but without the disagreeable symptom of dryness of the throat. The similarity of action between this drug and hyoscin is evidently overlooked by many physicians or is unknown to them, and this, in conjunction with the fact that many individuals show a marked idiosyncrasy for hyoscin should be borne in mind when using drugs of this class. Scopolamin hydrobromate is made by Merck, and differs little, if any, from the hydrobromid. It also occurs in hygroscopic crystals. The manufacturers claim that it may be used externally in ophthalmology and internally (by hypodermic injection) in insane patients. It is used for local anesthesia in conjunction with morphin. While reports of successful operations find their way into the newspapers and into medical literature, unsuccessful operations apparently are not noticed. Recently, however, numerous fatalities have been reported. De Maurans has reviewed the literature on this subject, and in a recent article in *Semaine Médicale* he discusses the advisability of using this form of anesthesia. In most of the cases reported there was interference with respiration, as evidenced by dyspnea and cyanosis, and the Cheyne-Stokes type of respiration. In one case cited, about half an hour after the second injection of the scopolamin-morphin solution when the patient was lying on the operating table he was observed to be breathing with difficulty, and about three minutes later there was dyspnea and cyanosis. Artificial respiration was performed, but the patient died about five hours after the injection, with symptoms of asphyxia. Dr. J. C. Sexton, in the *Lancet Clinic* for November 18, also reports a death from this form of anesthesia.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of Medical officers, U. S. Army, week ending December 2:

Wadhams, S. H., asst.-surgeon, leave of absence extended 30 days.

Bratton, Thomas S., asst.-surg., relieved from duty as attending surgeon and examiner of recruits, Chicago, and ordered to Philippine Islands, for duty, on January 5.

Wadhams, S. H., asst.-surg., relieved from further duty at Alcatraz Island, Cal., and will proceed from Torrington, Conn., where on leave of absence, to Fort Slocum, N. Y., for duty.

Connor, C. H., asst.-surg., ordered to proceed from Fort Stevens, Ore., to San Francisco, for duty as witness before a general court martial.

Ford, Clyde S., asst.-surgeon, ordered to proceed from Fort Barrancas, Fla., to Cleveland, Ohio, on official business pertaining to the inspection of a motor ambulance designed for the Medical Department of the Army.

Davidson, Wilson T., asst.-surg., advanced to the rank of captain, November 26.

Reagles, James, contract surgeon, returned to duty at Fort Keogh, Mont., from leave of absence.

Parkman, Wallace, contract surgeon, left Fort Assinniboine, Mont., with troops for San Francisco.

White, J. Samuel, contract surgeon, granted an extension of one month to his leave of absence.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending December 2:

Stuart, A., P. A. surgeon, detached from the *Pensacola* and ordered to command the Naval Hospital, Sitka, Alaska.

Bachmann, H. A., P. A. surgeon, commissioned P. A. surgeon from March 20, 1905.

Traynor, J. P., Strine, H. F., P. A. surgeons, commissioned P. A. surgeons from May 8, 1905.

Neilson, J. L., P. A. surgeon, commissioned P. A. surgeon from October 4, 1905.

Ransdall, R. C., asst.-surgeon, appointed asst.-surgeon from November 24, 1905.

Beyer, H. G., medical inspector, ordered to the *Wisconsin*.

Neilson, J. L., asst.-surgeon, detached from the naval hospital, New York, N. Y., and ordered to the naval hospital, Newport, R. I.

Shaw, H., asst.-surgeon, detached from the naval hospital, Boston, Mass., and ordered to the *Southery* and to additional duty at the navy yard, Portsmouth, N. H.

Vickery, E. A., asst.-surgeon, ordered to the *Illinois*, December 4.

Dorsey, B. H., asst.-surgeon, detached from the Illinois, December 4, and ordered home to wait orders.

Belknap, J. L., asst.-surgeon, detached from the naval hospital, Newport, R. I., and ordered to the *Brooklyn*.

Wheeler, L. H., asst.-surgeon, detached from the naval hospital, Newport, R. I., and ordered to the Asiatic station, sailing from Seattle, Washington, December 16.

Stepp, J., P. A. surgeon, detached from the *Southery*, and ordered to the *Don Juan de Austria*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ending November 29:

Magruder, G. M., surgeon, relieved from duty at San Francisco.

Magruder, G. M., surgeon, granted leave of absence for four months from October 26.

Guiteras, G. M., surgeon, to proceed to Memphis, Tenn., for special temporary duty.

Wertenbaker, C. P., surgeon, relieved from special temporary duty at Atlanta, Ga., and directed to proceed to St. John, N. B., for immigration duty, relieving P. A. Surgeon J. W. Kerr.

Rosenau, M. J., P. A. surgeon, leave of absence granted for fourteen days from November 22, amended to read November 23.

Nydegger, J. A., P. A. surgeon, granted leave of absence for one month and five days from November 27.

Gardner, C. H., P. A. surgeon, granted extension of leave of absence for one month, from December 1.

Lavinder, C. H., P. A. surgeon, leave of absence granted for one month from November 6, amended to read twenty-one days from November 6.

Fricks, L. D., P. A. surgeon, granted leave of absence for one month from December 10.

Wille, C. W., P. A. surgeon, granted leave of absence for two months, from December 10.

Rucker, W. C., assistant surgeon, leave of absence granted for seven days from November 7, amended to read twenty-one days from November 11.

Ward, W. K., assistant surgeon, granted leave of absence for four days under paragraph 191 of the regulations from November 23.

Foster, A. D., asst.-surgeon, relieved from special temporary duty at Trieste and directed to rejoin station at Naples.

Robertson, H. McG., asst.-surgeon, relieved from temporary duty at the Bureau, Washington, D. C., and directed to proceed to Philadelphia, reporting to the medical officer in command for duty.

Collins, G. L., asst.-surgeon, granted leave of absence for two days under paragraph 191 of the regulations from November 23.

Ebert, N. G., asst.-surgeon, granted leave of absence for two months from November 24.

Wightman, W. M., asst.-surgeon, granted three days' leave of absence under paragraph 191 of the regulations from November 13.

Steger, E. M., asst.-surgeon, relieved from duty at Philadelphia, and directed to report to the commanding officer of the Revenue Cutter *Algonquin* for duty on said vessel in Porto Rican waters.

Kastle, J. H., chief division hygienic laboratory, granted leave of absence for eight days from November 27.

Goldsborough, B. W., acting asst.-surgeon, granted leave of absence for three days from November 29.

Hallet, E. B., acting asst.-surgeon, granted leave of absence for three days from November 29.

Hicks, B. I., acting asst.-surgeon, granted leave of absence for four days from November 28.

Hume, Lea, acting asst.-surgeon, granted leave of absence for thirty days from November 26.

McConnell, A. P., acting assistant surgeon, granted leave of absence for three days from November 29.

Tarbell, B. C., acting asst.-surgeon, granted leave of absence for ten days from November 21.

Walkley, W. S., acting asst.-surgeon, granted leave of absence for three days from November 30.

Richardson, S. W., pharmacist, granted leave of absence for twenty-three days from November 23.

Stier, C., pharmacist, granted leave of absence for seven days from November 22, under paragraph 210 of the regulations.

BOARDS CONVENED.

Board to meet at the Bureau, Washington, D. C., December 4, for the physical examination of certain officers of the R. C. S. detail for the Board: P. A. Surgeon T. B. McClintic, chairman; Asst.-Surgeon J. W. Trask, recorder.

Board to meet at the Appraisers Building, San Francisco, December 4, for the physical examination of certain officers of the Revenue-Cutter Service. Detail for the Board: P. A. Surgeon H. S. Cumming, chairman; P. A. Surgeon J. M. Holt, Recorder.

Board to meet at Boston, December 4, for the physical examination of certain officers of the Revenue-Cutter Service. Detail for the Board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, Recorder.

Board to meet at the Marine-Hospital, Mobile, Ala., December 4, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the Board: P. A. Surgeon E. Francis, chairman; Acting-Asst.-Surgeon A. S. Taylor, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended November 27:

SMALLPOX—UNITED STATES.

California: Los Angeles, Nov. 11-18, 3 cases.
District of Columbia, Washington, Nov. 12-18, 1 case.
Florida, Jacksonville, Nov. 11-18, 3 cases.
Kentucky: Covington, Nov. 18-25, 8 cases.
Maine: Westport, Nov. 21-23, 2 cases.
Michigan: Kalamazoo, Nov. 12-18, 3 cases.
Missouri: St. Louis, Oct. 1-31, 12 deaths.
Ohio: Springfield, Nov. 17-24, 2 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, Oct. 1-7, 4 cases.
Brazil: Rio de Janeiro, Oct. 15-22, 7 cases, 2 deaths.
Canada: Toronto, Nov. 11-18, 4 cases.
Chile: Iquiqui, Oct. 14-21, 7 cases, 2 deaths.
Ecuador: Guayaquil, Oct. 24- Nov. 7, 9 deaths.
France: Paris, Oct. 29-Nov. 4, 8 cases, 1 death.
Great Britain: Sheffield, Oct. 29-Nov. 4, 1 case.
Italy: Catania, Nov. 2-9, 3 deaths.
India: Calcutta, Oct. 1-14, 2 deaths; Madras, Oct. 14-27, 9 deaths.
Mexico: Mexico, Oct. 22-Nov. 4, 3 cases, 6 deaths.
Spain: Barcelona, Nov. 1-10, 6 deaths.

YELLOW FEVER—UNITED STATES.

Louisiana: New Orleans, Nov. 21, 2 cases.
Mississippi: Vicksburg, Nov. 24-29, 3 cases.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Oct. 15-22, 2 cases, 2 deaths.

Cuba: Habana, Nov. 10-20, 25 cases, 2 deaths; Matanzas, Nov. 25, 1 case.

Ecuador: Guayaquil Oct. 22-Nov. 7, 7 deaths.

Honduras: Choloma, Nov. 13, 1 death.

Guatemala: Gualan, Aug. 20-Nov. 9, (estimated), 200 deaths; Zacapa, Aug. 3-Nov. 9 (estimated), 700 deaths.

Mexico: Cordoba, Nov. 5-8, 1 case, 2 deaths; Tezonapa, 1 case, 3 deaths; Tierra Blanca, 2 cases, 1 death; Tuxtepec, Nov. 5-19, 4 cases, 3 deaths; Vera Cruz, 3 cases, 3 deaths.

Nicaragua: Managua, Sept. 29, 3 cases.

Panama: Colon, Nov. 8-15, 1 case, 1 death; Panama, 1 case.

CHOLERA—FOREIGN.

India: Bombay, Oct. 17-24, 1 death; Calcutta, Sept. 23-Oct. 21, 178 deaths; Madras, Oct. 14-27, 123 deaths.

Russia: Lodz, Oct. 22-25, 4 cases; Vistula Territory, 6 cases; Lomja, 1 case; Warsaw, Oct. 17-24, 2 cases, 4 deaths.

Straits Settlements: Singapore, Oct. 1-7, 3 cases.

PLAGUE—INSULAR.

Honolulu: Oct. 7-Nov. 4, 8 cases, 8 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Oct. 15-22, 9 cases, 1 death.

Egypt: Alexandria, Nov. 8, 1 case.

India: General, Oct. 14-21, 4407 cases, 3336 deaths; Bombay, Oct. 17-24, 19 deaths; Calcutta, Sept. 30-Oct. 21, 32 deaths; Karachi, Oct. 15-22, 22 cases, 23 deaths.

Japan: Kobe, Nov. 20, present; Osaka, present.

Medical Organization

OREGON PRACTICALLY AN UNORGANIZED STATE.

By J. N. McCormack, M.D.

Chairman of the Committee on Organization of the American Medical Association.

BOWLING GREEN, KY.

Being an amiable optimist by nature, adverse criticism of any one, and more especially of those who have been kind to me, is always a difficult and unpleasant task. Still, I conceive it to be my duty after visiting a state in my official capacity, kindly and subject to correction always, but frankly and without fear or favor, to discuss professional conditions just as my investigations revealed them. In fact, years of experience have convinced me that this is the only course to pursue where reforms are to be hoped for, and that if it is done in the proper spirit, and is supplemented by such practical suggestions as may seem pertinent, and may prove helpful, it will never be misunderstood.

Outside of Astoria and Clatsop County there is little real organization in Oregon. Factionalism in the profession in the city of Portland, led by rival surgeons and other specialists, is almost entirely responsible for this demoralization in the state. In my opinion there is no hope for improvement until this is recognized and this strong and excellent profession can be harmonized and united for its own and the public good, in accordance with the modern spirit of organization.

They have a live local society of the old sort, honeycombed with and dominated by rival factions, most respectful and decent in form and expression, as might be expected from such leaders, but so evenly balanced and alert as to consume nearly all of their public energies, and so evidently personal and selfish as to fail to enlist the support or to command the confidence of the rank and file of the profession of the city or state for either side, and to effectually bar progress for it as a whole. The information came to me from various sources that many of the most active and influential physicians were outside of the society, some because they were kept out by factional jealousies and more because membership did not seem desirable under existing conditions. For instance, when it was suggested in my opening talk that a united profession ought to enlist the support of the press in the proper education of the public in regard to health and medical affairs and in the warfare against quackery, and that the family physicians of the leading newspaper men be put on a committee to confer with them, it developed that the physician of the most promient editor of the state had been repeatedly blackballed by the society and hence could not well be asked to serve in this capacity.

These statements will come as a surprise to members of the Association who attended the Portland session and enjoyed the hospitality of the profession of that beautiful city. This surprise was only intensified with me when the opportunity for a more extended and personal acquaintance, and inquiry has confirmed my first impression of the high character and capability of the very men who were contributing most to the discord which is proving so disastrous to the best interests of the profession and people of their city and state.

To appreciate the extent to which these unfortunate professional conditions in Portland affect the state, it should be remembered that it is the only great center of population and commercial metropolis in Oregon, and that this city dominates in legislative and all other affairs to an extent which would be possible in few other states. And the state reflects the conditions found in the city very acurately. They had paper organizations in every county or district visited by me, meeting at long intervals and thought important chiefly as a means of keeping up membership in the state and national organizations. There were a few good men everywhere, but the average grade of the profession was low and the spirit non-progressive. Their law is weak and is so administered as to give quacks and pretenders no trouble. There was evidence on every hand that the schools of Oregon do not have high standards of requirements, and that their state examinations are such as to make this the dumping ground for low-grade men who fail to pass in neighboring or even distant states. The fees are much lower than in any other state visited on this trip, and commercialism—division of fees, lodge and other forms of contract practice, and similar evils—is more pronounced and widespread. I heard many apparently reputable men say over and over again that they would not think of sending a case to any surgeon who would not divide his fees with them. Similar expressions and other evidences of improper or defective methods inseparable from an unorganized profession were heard and found frequently. In the same locality would be found men of high attainments and character, natural leaders, who could easily become the backbone of a county society and make almost anything possible to the profession.

I urged such local organizations in every county where there were as many as three or four live physicians as would make their society a place for joint study, in effect a postgraduate or review school, and a social and business club. After they are thoroughly united and ready for it, I advised that the bar, ministerial, teachers, druggists' and other similar local associations be invited to meet with them for such discussion and joint instruction as will promote a co-operation so essential to the highest development and usefulness of our profession. I advised that legislators and other officials be especially invited to take part in these discussions in order that they may appreciate how largely the profession is influenced by purely altruistic motives in its efforts to secure and to enforce medical and health legislation.

I attended and addressed meetings at Astoria, Portland, The Dalles, Salem, Albany, Eugene, Grant's Pass and Medford, covering all except the eastern end of the state. Dr. Hamilton, the active and courteous secretary of the state association, gave prompt notice of the meetings, and as the medical population is practically confined to the towns, the meetings were fairly well attended.

The Astoria and Clatsop County Society is entitled to special and honorable mention, not only because it is an oasis in Oregon, but because it would be a credit to the profession in the best organized states. It is almost three years old, with every physician in the county, including two former homeopaths, and, I believe, one eclectic, enrolled as members. With the exception of one who lived twelve miles away, on the opposite side of the Columbia River, and was hindered by a fierce storm, every member was in attendance at the meeting held for me. Three circuit judges, the bar association and other laymen were present and took a leading part in both the discussion and the banquet which followed. These laymen had attended former meetings and contributed much to the interest and usefulness of the society, especially in the adjustment of the business affairs of the profession. The leaders of the profession in this county had grasped the co-operative spirit of this reform movement in a practical way at the outset, and as soon as the state association adopted the new plan, decided to give themselves the benefit of it. After a few conferences they succeeded in substituting harmony and co-operation for the discord and antagonism which had been as pronounced there in the past as it could have been anywhere. After uniting the profession solidly they abolished all lodge and contract practice in one week's time. A little later they revised their schedule of fees and put collections and the other business affairs of the profession on a modern basis, satisfactory alike to themselves and their patrons. They were most responsive to my suggestion for frequent meetings and systematic study, and promised to take prompt steps to this end, and also to enter into co-operative educational work with the other learned professions and the public generally. Altogether this impressed me as one of the most united and promising local societies to be found in any part of the country. If the profession of Portland could be induced to unite in this work, and would expend the energies on it in the future which its leaders have wasted in the past, the foundation for real organization could be laid before the next annual meeting of the state association, and plans made for legislative and other much needed reforms. Many of the smaller counties could undertake the work as successfully as Clatsop County did, without the assistance of Portland, and with the profession there in discord, but I got the impression that a majority of them would not do so.

My personal experience in Oregon was most pleasant. Mrs. McCormack was with me everywhere, and the physicians and their families vied with each other in contributing to our entertainment and comfort. I am tempted to mention individuals in this connection, but the hospitality was so general and generous that this will not be attempted. If a profession with such leaders could only be unified everything would be possible to it, and it is in the hope of arousing them to this duty that I have hesitatingly and reluctantly expressed these criticisms.

Iowa.

POCAHONTAS COUNTY MEDICAL SOCIETY.—We have received the program of the annual meeting of this society and find it suggestive of methods that will accomplish much good. Both an afternoon and evening meeting are provided for, with dinner between. The afternoon program is filled with regular medical papers and business. This is the purely professional and scientific part. Then follows dinner; this is the social—a very important—part, for it is this that brings men together, makes them understand and know each other, and thus dissipates jealousies. In the evening is the public meeting, at which the patient and the physician meet on a common level. The program before us states that at this meeting, besides music and recitations, three papers are to be heard: "Preventive Medicine and the Relation the Public Bears to the Profession," by a member; "The Public School as a Factor in the Public Health," by the superintendent of public schools, and "The Doctor—Both Sides of Him," by a member. This will be the second meeting of this society to which the public has been invited, the former experiment having been a success.

This method of educating the public is being adopted by but a few isolated societies; it should be utilized by every county society in the country. The public wants to learn, is ever open to conviction, and a free interchange of views between the layman and the physician will result in good to both. The teacher, the lawyer, the editor will attend such meetings and the public-spirited citizen will always be a willing co-operator. These will leaven public opinion. There should be open, free discussion of business matters in these public meetings, as well as of the ethics of medicine and of health and disease.

We have one criticism to offer on the program of the Pocahontas society; it is that no provision is made for discussion at the public meeting. Less music and fewer recitations and time for discussion will make more interesting gatherings and bring about better results. It is the heart-to-heart talks that are wanted.

Kansas.

ALLEN COUNTY MEDICAL SOCIETY DID NOT DISBAND.—The following seems to be a morsel that is pleasing to a certain class of newspapers, for it has appeared in many of them:

> SHORT-LIVED SOCIETY.
>
> At Iola, Kansas, Thursday, the physicians of the county met and organized a society, fixing rates, all being the same. On Friday,

the prosecuting attorney of the county had warrants issued for the arrest of every physician in the county who joined the society, for the purpose of prosecuting them under the anti-trust law. The physicians were given until next Monday to disband their organization and they gave it out that they would do so.

We sent a clipping to the secretary of the society referred to, who has replied as follows:

"The Allen County Medical Society is now and has been in existence for nearly two years. Our old original society is three years old. We disbanded and reorganized March 28, 1904, in order to affiliate with the State Medical Society. We believe we have one of, if not the best county society in the state, and have our state charter. The meeting referred to was our regular meeting, which is the third Wednesday in each month. At this meeting we revised our fee bill, and our prosecuting county attorney merely stated to us that in his opinion we had violated the anti-trust law by agreeing to the fee bill. No warrants were ever issued, nor will there be any issued, as we will correct the matter at our next meeting. I desire that you publish this letter to show to the world, and especially to the medical profession, that newspapers are many times unreliable, especially along medical lines.

"J. W. Bolton, Secretary Allen County Medical Society."

Society Proceedings

COMING MEETINGS.

Southern Surgical and Gynecological Association, Louisville, Ky., Dec. 12-14.

American Dermatological Association, New York, Dec. 28-30.

Western Surgical and Gynecological Association, Kansas City, Mo., Dec. 27-28.

AMERICAN TUBERCULOSIS EXHIBITION.

Held in New York City, Nov. 27 to Dec. 8, 1905, under auspices of the National Association for the Study and Prevention of Tuberculosis and the Committee on the Prevention of Tuberculosis of the Charity Organization Society at the American Museum of Natural History.

The idea of the exhibition is to show the methods that are being adopted throughout this country and Europe to prevent and to cure consumption. Toronto, Canada, had on exhibition the model of a tuberculosis sanatorium. There were models of sanatoria which are in use in the different states. Chicago sent models of her hospital buildings for this disease. Pennsylvania also had a fine exhibition, the institution at White Haven being specially deserving of mention. New York State had a large model of the sanatorium at Raybrook, which has been in operation two years. New York City showed how it takes care of its tuberculosis patients in tents on Blackwell's Island and in other places. There were several model tents and contrivances by which the sick person can breathe fresh air both day and night. There were also models of improved tenement houses which are a feature of the general plan for the prevention of the spread of tuberculosis. In contrast with these were specimens of the old-time dark bedrooms which are held responsible for a great deal of tuberculosis in the city.

Economics of Antituberculosis.

Dr. Thomas Darlington, health commissioner of the city of New York, presided at the opening meeting, November 27.

Morris K. Jesup, in the opening address, said that if the people could awaken to the awful condition of the poor who are afflicted with this disease the effort they would make would result in vanquishing this plague.

Dr. Thomas Darlington said that the object of the exhibition was to educate the public in regard to the prevalence of consumption and to teach them the best methods of prevention and cure. He spoke of what it would be worth to the city and to the individual if we could eradicate this disease. He said that the cost of educating a child is about $50.00 a year in the public schools; yet 24 per cent. of the deaths from tuberculosis occur between the ages of 15 and 25. He asked what is the use of educating children if they are going to die before they are able to use their education. If we are going to take such great pains and expense in their training we are morally bound to look to their physical condition as well. There are 28,000 cases of tuberculosis in Greater New York. The Board of Health is endeavoring to aid these by sending nurses, by clinics, by visiting physicians and by the distribution of literature. The greatest difficulty they encounter is the failure on the part of physicians to report cases of this disease. He thought, however, that at the present time from 90 to 95 per cent. of the cases are reported. During the past year 19,000 sputum examinations have been made, of which 6,000 proved not to be tuberculosis. Some of the worse cases were curable; 8 per cent. of the bad cases on North Brothers Island recovered and 60 per cent. were improved. He emphasized the necessity of an early recognition of the disease. The lungs of school children were now examined and adenoids removed. Forty-eight per cent. of the school children had something wrong which very often laid the foundation for tuberculosis. He urged more sanitary conditions in factories, shops and houses. After the death or removal of a tuberculous patient the Board of Health disinfects the rooms. He thought expectoration in public places could not be effectually done away with by law, but only by an educated public opinion. He strongly deprecated the use of patent medicine and drugs in combating this disease, as in most instances they are only alcoholic stimulants.

Talcott Williams, of Philadelphia, said that civic responsibility is just as direct and necessary in dealing with this disease as in dealing with political corruption. Our only hope lies in knowledge and in the education of the masses. He said that every case of consumption is a visible proof of social failure; the remedy is an individual sense of responsibility. If there are 5,000 deaths from consumption on the island of Manhattan, practically all of which can be prevented, and from 10,000 to 15,000 cases which could be saved from death, it is because neither the city nor the citizens have discharged their duty.

Health for Workers.

Dr. Thomas Darlington presided at the meeting held on November 29. The subject discussed was "Health for Workers."

Herman Robinson, of the Central Federated Union, said that organized labor was doing all in its power to better social conditions in general, but particularly in connection with tuberculosis. It had made many workshops more healthful and was using every effort in that direction from day to day.

Prof. Graham Taylor, of Chicago, spoke of the work in the West and told what had been accomplished there.

J. W. Sullivan, editor of the official publication of the garment workers and a member of the Typographical Union, told what had been done to improve sweatshop conditions, and called attention to the interesting collection of photographs illustrating the fearful conditions still existing in East Side sweat shops.

Recent and Coming Congresses.

On Friday evening, December 1, with **Dr. Hermann M. Biggs** in the chair, **Dr. Lawrence F. Flick**, of Philadelphia, gave a brief history of the various tuberculosis conventions held since 1898 and outlined a plan for a congress to be held in Washington in 1908. He proposes that the expenses of this congress be defrayed by asking for $100,000, which could be raised by twenty wealthy men subscribing $5,000 each. It is his intention to endeavor to get this money at once and to permit it to remain undisturbed until 1908, when the accumulated interest will be distributed in prizes. He would give prizes on this occasion for the best exhibits from any country, for the best set of laws and ordinances dealing with conditions affecting tuberculosis, for the best sanatorium, the best pavilion, the best hotel, the best factory or workshop, etc. He proposes that the scientific portion of the congress be continued for one week in Washington, and that the social portion one week preceding and one week following the scientific sessions be held in various cities.

Dr. Edward L. Trudeau, Saranac Lake, spoke of the work of sanatoria and said that he believed that future work in dealing with tuberculosis would be along the lines of specific treatment.

Dr. W. A. Evans, Chicago, member of the Tuberculosis Commission said that Chicago needed more agitation in regard to the means of getting rid of this disease. Chicago had but from $1,500 to $2,500 with which to combat this disease; in fact, only the small fines secured from milk dealers and a few other petty offenders. In every instance we should seek the assistance of societies or other agencies working along kindred lines in our work against tuberculosis. Not more than 2 per cent. of consumptives are able to leave home and we must find a way to cure them at home. We must keep on trying to teach the value of fresh air and fighting the draught fiends. Consumption should not be viewed as an infectious disease alone, but should be regarded as something more if we ever expected to entirely eradicate it. If we were ever to make this scourge disappear we must learn to live more hygienic and more simple lives.

Dr. Vincent Y. Bowditch, Boston, said that he wished to sound a conservative note in regard to statements as to the results in the treatment of tuberculous subjects. This is too treacherous a disease to speak too early or with too much certainty of our successes. Too precipitate statements from physicians and overstatements of the press are harmful to the cause.

Exile and Drugs in the Treatment of Tuberculosis.

Dr. Abraham Jacobi, of New York, related the trials of the poor patient afflicted with tuberculosis and showed how impossible it is for him to go away from home in most instances. Statistics show that there is only one bed in a sanatorium for every 30 persons having tuberculosis; consequently home treatment has to be instituted. Much was said about Nature's remedies, fresh air, good food, etc., but drugs were Nature's remedies, too, and should not be neglected in every case. When in a family we see child after child show signs of tuberculosis it is well to look for syphilis in the mother. We should be careful to keep mucous membranes in a healthy condition and to see that enlarged tonsils are properly cared for. By proper attention to such matters one often obviates the necessity of treating consumption later. We should teach the value of exercise, cold water, a copious supply of oxygen, and that night air is better than no air. In addition to air, food and clothing we should recognize that there are drugs which, if wisely used, will help us in the treatment of this disease. In his hands guaiacol has given some very encouraging results, especially in the treatment of renal tuberculosis.

(*To be continued.*)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Early Pulmonary Tuberculosis.

Price, in *Edinburgh Med. Jour.*, states that the cough which occurs early in the morning and which is accompanied by expectoration, is of service and should be encouraged. For the cough at night he recommends a cup of hot milk or cocoa, or tea, at bedtime, and occasionally through the night. In some cases he recommends a sufficiently warm alkaline draught similar to the following:

℞. Sodii bicarb..........................gr. x |65
Sodii chloridi ....gr. v |30
Ammon. carb..........................gr. iii |20
Spts. chloroformi..........................m. v |30
Aq. anisi q. s. ad..........................℥i 30|

M. Sig.: At one dose in a wineglassful of warm water or milk.

In some of these cases of early tuberculosis in *which the* cough is troublesome a small blister or iodin is recommended, applied to the subclavian region on the *affected side. An* irritable and ineffectual cough persisting through the *day, accompanied* by a very scanty expectoration after prolonged efforts, is best managed by instructing the patient *to restrain* the cough as much as possible and to use an *inhalation containing* menthol, creosote, oil of eucalyptus or oil of pine. A combination similar to the following is recommended in some cases:

℞. Olei euclaypti ....ʒiii 12|
Olei amagdylæ amaræ..........................ʒi 4|
Spts. chloroformi ....℥i 30|

M. Sig.: From 10 to 75 drops to be inhaled, half an hour after the first morning cough; again at noon and in the evening. Or the following may be used as a modification of Dr. Coghill's formula:

℞. Tinct. iodi ether (Br.)
Acidi carbol., āā..........................ʒii 8|
Creosoti ....ʒi 4|
Spts. vini rect., q. s. ad..........................℥i 30|

M. As an inhalation. Or:

℞. Sol. menthol alc. (20 per cent.)........ʒii 8|

Sig.: Ten *minims placed* in an inhaler and inhaled for one-half hour. Or:

℞. *Creosote*
Sol. menthol alc. (20 per cent.)
Spts. chloroformi, āā..........................ʒi 4|

M. Sig.: Twenty drops to be inhaled from a sponge for one hour.

In case the foregoing combinations do not check the cough sufficiently this author recommends that a 2 per cent. solution of cocain be sprayed on the back of the throat. In some cases ipecac, potassium iodid or sodium bromid may be of value. Anodynes should be the last resort in these cases.

If the expectoration is peculiarly tenacious ammonium chlorid should form a part of medical treatment.

In the later stages of the disease, when the secretion is excessive, the internal administration of balsams or the inhalation of antiseptics such as creosote or turpentine, is the best treatment. If the patient shows indications of becoming exhausted during the night from the aggravated cough it will probably become necessary to administer some form of opium. There is danger, however, of upsetting the stomach, and this must be avoided if possible. Codein is less liable to disturb the stomach than the other preparations of opium. The following combination is recommended:

℞. Codeinæ ....gr. 1/6 |01
Acidi citrici..........................gr. v |30
Spts. chloroformi..........................m. v |30
Mucil. acaciæ ....ʒi 4|

M. Sig.: To be taken at one dose and repeated as the individual case requires.

If paroxysms of coughing arise which terminate in vomiting of food, the patient should be instructed to lie perfectly quiet after a meal. In some such cases the following is advised by the author:

℞. Aluminis ....gr. v |30
Liq. potassæ ....m. v |30

M. Ft. cap. No. i. Sig.: To be taken just before nourishment.

If hemoptysis should arise and is sufficient in amount to require *treatment, rest in bed* is the important measure; this lowers blood *pressure, slows the circulation* and diminishes the movements of the lung. The patient should lie in the recumbent position with the head *and shoulders* elevated. And all unnecessary movements and *talking should* be prohibited. Warmth should be applied to the feet if the patient feels chilly.

All stimulants must be withheld, the food must be cold and limited to a pint and a half of *milk* a day, *two* ounces of meat essence, four ounces of bread *and one-fourth* ounce of butter. An icebag may be of value applied to the chest, but the author states very aptly *that its only value*, perhaps, is in preventing the patient from sitting up, and similarly, the sucking of ice for the time *soothes the* cough and causes the patient to believe that something is being done *for* him.

One of the most *important* means of checking hemoptysis, according to this writer, is *to lower* blood pressure by means of catharsis and free *purgation. He* recommends saline purgatives as the most *valuable*, such as the following:

℞. Sodii sulphatis..........................
Magnesii sulphatis ....gr. xx 1|30
M. Ft. pulvis. Sig.: One such powder every *four* hours. ....ʒi 4|

In cases in which hemoptysis is *profuse* a hypodermic injection of morphin may be given and repeated sufficiently often to keep the patient partially under the *influence* of the drug for several days. [Morphin, however, should be used only when absolutely necessary, and then with great caution.—Ed.] The only hemostatic from which the author has obtained results is the oil of turpentine given in 10-minim doses. Also ergotin is recommended hypodermically in doses of grains 1 to 3 (.06 to .20) as a hemostatic.

When hemorrhage of the lungs comes on suddenly and in considerable amount, so that the patient's strength is reduced and he becomes nervous, Thompson, in his *Practical Dietetics*, recommends absolute quiet in bed without a pillow, so that the body may be flat and the head and arms should on no account be raised. The patient should not be allowed to feed himself. A nurse should be in charge and small quantities only of food should be given at one time through a glass tube or by a teaspoon, so that the head need not be raised. If nausea occurs every effort must be put forth to control it, otherwise the muscular effort may bring on another hemorrhage. The blood pressure in the lungs must be reduced in order to allow the coagulation of blood to occur over the oozing surface, therefore, large quantities of fluid should not be taken at one time. The patient is usually thirsty from the loss of blood and temporary drying of secretions. The thirst may be relieved by crushed ice and small quantities of cold acidulated drinks, such as very dilute phosphoric acid or sour lemonade, and if the condition of the stomach is in proper condition, plain milk may be given, otherwise pancreatized milk and strong beef broth not exceeding two or three ounces in as many hours. The advantage of administering all fluids cold, according to this author, is overrated. Warm fluids have a somewhat more stimulating effect on the heart and are more rapidly absorbed, but the theory that cold taken in the stomach exhibits any great reflex, constricting action on the blood vessels of the smaller bronchi is not a rational one, according to this author.

In cases in which exceptionally large hemorrhages occur with a consequent loss of blood, it becomes necessary to give larger quantities of fluid, and salt water injections may be resorted to.

If there is no return of hemorrhage after one or two days the diet should be increased and the anemia consequent on the bleeding must be treated by abundant meat diet, avoiding alcoholic stimulants unless danger of heart failure should arise.

In the administration of cod-liver oil in tuberculosis the following combination after Bricemoret is recommended in *Twentieth Century Pract. of Med.*:

℞.	Olei morrhuæ	℥xii	360	
	Syr. tolutani	℥vi	180	
	Tincturæ tolutani	gr. xii		75
	Olei caryophyilli	gtt. ii		12

M. Sig.: Shake the mixture well and take one tablespoonful two or three times a day.

Iodoform, which is also recommended by some authorities in all degrees of phthisis, is recommended in the following combination:

℞.	Iodoformi	gr. iss		09
	Codeinæ	gr. 1/3		02
	Ext. cascaræ	gr. ss		03

M. Ft. pil. No. i. Sig.: One such pill three times a day.

If diarrhea is present the following is recommended:

℞.	Iodoformi	gr. xxx	2	
	Acidi tannici	gr. lx	4	

M. Ft. chart. No. xl. Sig.: From two to four powders daily.

Cinnamon has many advocates as a remedial agent in tuberculosis and may be combined as follows:

℞.	Quin. sulph	gr. vi		40
	Tinct. cinchonæ co.			
	Syr. aurantii, āā	℥iss	45	
	Aq. cinnamomi q. s. ad	℥viii	240	

M. Sig.: One tablespoonful three or four times a day. Or:

℞.	Essentiæ thymi			
	Essentiæ eucalypti			
	Essentiæ cinnamomi, āā	m. lxxx	5	20
	Olei olivæ (sterilized)	℥iiiss	105	
	Iodoformi	gr. lxxv	5	
	Bromoformi	m. xxx	2	

M. Sig.: Forty-five minims to be dropped into the trachea once a day.

Prescription for Asthma.

A correspondent calls our attention to an error in a prescription in The Journal, Nov. 25, 1905, page 1688. As corrected the prescription should read as follows:

℞.	Tincturæ lobelia	m. x		6
	Heroin hydrochloratis	gr. 1/24-1/2		0027-.0054
	Ammon. muriatis	gr. v		3
	Spiritus ætheris comp. q. s. ad	ℨi	4	

Medicolegal

Restriction on Use of Wood Alcohol.

Chapter 274 of the Laws of Wisconsin of 1905 provides that no person, firm or corporation shall require or wilfully permit the use of wood alcohol, or shellac or other material dissolved or mixed with wood alcohol, or columbian spirits, within any vat or tank, in such manner as to cause injury to or endanger the life or health of the person so using it, or of any other person.

Change in Requirements.

Chapter 41 of the Laws of Washington of 1905 amends section 3 of the act regulating the practice of medicine and surgery in that state by providing that each applicant for a license "shall be a graduate of some duly authorized medical college now having, if it still be in existence, at least a four years' graded course." The fee for examination shall be $25. And there is nothing said about reciprocity.

Provision for Prevention of Contagious Diseases.

Chapter 333 of the Laws of Wisconsin of 1905 appropriates to the State Board of Health a sum not exceding $50,000 for the two years ending Feb. 1, 1907, which shall be for a fund which, by and with the advice and consent of the governor, may be drawn on by the said board and used by it in such manner as may seem to it to be necessary to prevent the introduction or spread of Asiatic cholera or other dangerous contagious diseases in the state.

Must Report Tuberculosis.

Chapter 55 of the Laws of Utah of 1905 provides that it shall be the duty of every physician in the state, every superintendent of hospital or public institution in the state to immediately report to the State Board of Health every case of tuberculosis which he is called on to treat or which is in such hospital or public institution. Each and every physician or superintendent shall make such reports as may be called for by the rules and regulations made by said board to prevent the spread of such disease. Any person violating any provision of this act shall be guilty of a misdemeanor.

No Formaldehyd in Milk or Food Products.

Chapter 50 of the Laws of Washington of 1905 provides that any person who shall sell, offer to sell, or have in his possession for the purpose of sale, either as owner, assistant, or in any manner whatsoever, whether for hire or otherwise, any milk or any food products, containing the chemical ingredient commonly known as formaldehyd, or in which any formaldehyd or other poisonous substance has been mixed, for the purpose of preservation or otherwise, shall be guilty of a felony, and on conviction thereof shall be imprisoned in the penitentiary for a period of not less than one year nor more than three years.

No Advertising to Cure Venereal Diseases.

Chapter 78 of the Laws of Washington of 1905 provides that any person who shall advertise that he will treat or cure venereal diseases or disorders, or any venereal disease or disorder shall be guilty of a misdemeanor, and on conviction thereof shall be imprisoned in the county jail for a period of not less than one month nor more than six months. Any owner or managing officer of any newspaper in whose paper shall be printed or published such advertisement as is described in this act shall be guilty of a misdemeanor, and on conviction thereof shall be imprisoned in the county jail for a period of not less than one month nor more than six months.

Provides for State Tuberculosis Sanatorium.

Chapter 361 of the Laws of Wisconsin of 1905 provides for what is to be known as the Wisconsin State Tuberculosis Sanatorium for the treatment of pulmonary tuberculosis, especially for cases in the incipient stages of this disease. The general supervision and government of this sanatorium, except the financial supervision, shall be vested in an advisory board, which shall consist of five members appointed by the governor, one of whom shall be a member of the State Board of Health and at least two other members shall be licensed physicians, graduates of a reputable medical college. Applicants for admission to the sanatorium shall be examined at various places throughout the state designated by the advisory board.

State Hygienic Laboratory Continued.

Chapter 471 of the Laws of Wisconsin of 1905 continues for a period of two years at the state university in conjunction with the existing laboratories in bacteriology, the laboratory which was authorized by the legislature of 1903, known as the Wisconsin State Hygienic Laboratory. The purpose of this laboratory shall be to undertake the examination of water supplies for sanitary purposes, the examination of material from various contagious and infectious diseases with the purpose of aiding in the determination of proper diagnosis of such diseases, to examine into the nature and cause of disease outbreaks throughout the state, to study hygienic and sanitary problems relating to diseases and their dissemination, or any other problems that bear directly or indirectly on the public health.

Duties of Physicians Relative to Certain Diseases.

Chapter 192 of the Laws of Wisconsin of 1905 provides that in every city of the first, second, third and fourth classes it shall be the duty of every physician to report to the department of health in every such city, in writing, the full name, age and address of every person suffering from any one of the infectious or contagious diseases following, to-wit: Measles, smallpox, diphtheria (membranous croup), scarlet fever (scarlatina), typhoid fever, tuberculosis (of any organ), rubella (rötheln), chickenpox, typhus fever, plague, erysipelas, Asiatic cholera, whooping cough, cerebrospinal meningitis, yellow fever. It shall be the duty of every physician to report forthwith in writing to the said department of health the death of any person who dies from, or while suffering with or from any infectious or contagious disease, and to state in such report the specific name and type of such disease.

It shall be the duty of every physician, etc., in any such city, to report to the department of health thereof, in writing, or to cause such report to be made by some proper and competent person, the name, age, sex, occupation and latest address of every person afflicted with tuberculosis, who is in their care, or who has come under their observation, within one week of such time. It shall be the duty of every person sick with this disease, and of every person in attendance on any one sick with this disease, and of the authorities of public or private institutions or dispensaries, to observe and enforce all the sanitary regulations of such health department for preventing the spread of pulmonary tuberculosis.

In case of the vacation of any apartment or premises by death from tuberculosis, or by the removal therefrom of a person or persons sick with tuberculosis, it shall be the duty of the person or physician in charge, to notify the commissioner of health of such city within twenty-four hours thereafter, and such apartments or premises so vacated shall not again be occupied until duly renovated and disinfected as herein provided. In case any orders or directions of the commissioner of health requiring the disinfection of any articles, premises or apartments shall not be complied with within thirty-six hours after such orders or directions shall be given, then it shall be the duty of the commissioner of health to cause a placard in words and form as follows, to be placed on the door of the infected apartments, or premises, to-wit:

NOTICE.

Tuberculosis is a communicable disease. These apartments have been occupied by a consumptive and may be infected. They must not be occupied until the order of the health commissioner directing their renovation and disinfection has been complied with.

This notice must not be removed under a penalty of law, except by the commissioner of health, or an authorized officer.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

November 25.

1 *Yellow Fever in Cuba. J. Guiteras, Havana, Cuba.
2 *Relation of Stomach Disorders to Diabetes Mellitus. J. P. Sawyer, Cleveland, Ohio.
3 *Ambulant Treatment of Internal Hemorrhoids. C. F. Martin, Philadelphia.
4 *Disinfection of Dwelling Houses and Bedding. A. H. Stewart, Philadelphia.
5 *Purpura [illegible] Report of a Case Occurring During [illegible] veringen, Ft. Wayne, Ind.
6 Perniciou[illegible] Disappearance of the Parasite. H. D. Bloombergh and J. M. Coffin, U. S. A.

1. **Yellow Fever in Cuba.**—Guiteras relates the circumstances of the last days of yellow fever in Havana, and uses the facts as arguments in support of the view that the mosquito is the only means of transmission of the disease. As some doubt has been expressed by some as to the demonstrative value of the experimental cases produced by Guiteras at Las Animas Hospital, he shows that there could have been no other source for the infection than the experimental application of the infected mosquito. He relates further how the disease has been introduced several times into Cuba without its ever taking a foothold in that old home of the disease, though the Las Animas Hospital may be looked on as a veritable powder magazine charged with explosives in the shape of accumulated fomites.

2. **Relation of Stomach Disorders to Diabetes Mellitus.**—Sawyer reports 19 cases which show that much may be accomplished for the comfort and relief of many diabetics by direct attention to the condition of the stomach. Of these 19 patients, 14 gave evident histories of previous dyspeptic trouble, 1 of alcoholism without dyspepsia, 3 of slight indigestion, and only 2 reported a complete freedom from dyspeptic disturbance. As to the duration of the glycosuria, 9 of the 19 have been diabetic for years, 7 for months, 1 possibly for a month, while in 2 the period is thought to have been from one to six weeks. From these considerations, as well as from the clinical history, all may be excluded from the range of alimentary glycosuria. Among them were cases of the severest type, as well as of the milder forms. With reference to the condition of the stomach, 16 show abundant catarrhal mucus in the contents of the stomach; 2 do not show this catarrhal process, and from 1, owing to age and disinclination, no test meal was obtained. As to motor function, 10 show a considerable failure, and of the 18 patients the secretion of hydrochloric acid in 8 is increased; 7 show normal proportions, 3 show less than normal or absent. Of the 19 patients all but 2 show definitely active catarrhal processes, and in every case of the 18 there has been marked subjective benefit—gain in strength, weight, freedom from thirst, and polyuria—gained by direct attention to the catarrhal process. The most striking effect has been observed on the polyuria and thirst. In some cases the percentage of sugar has undergone no change, but there has been in these cases a great reduction of the total excretion of sugar *per diem*, owing to the great change in the quantity of urine excreted, and the clinical course of this group of diabetics has been much more favorable under direct treatment of the stomach than without it. Moreover, the cessation of this treatment has been followed by the recurrence of the difficulty with prompt relief on resuming the treatment directed to the catarrhal process. In most of the cases lavage formed an important part of the treatment, antiseptic and alkaline solutions being used.

3. **Ambulant Treatment of Internal Hemorrhoids.**—Martin asserts that the treatment of internal hemorrhoids by hypodermic injection has fallen into disrepute among surgeons because it is the accepted method of the advertising quack. The many complications and accidents must not be ascribed to the method itself, but to the unscientific and insanitary technic employed by this ignorant class of irregular practitioners. It is to be remembered, Martin states, that the injection method is a surgical procedure as truly as the clamp and cautery or the ligature operations, and, therefore, is not a method to be

employed by the general practitioner. The advantages of the injection method are that the patient need not give up his business while under treatment and is not required to take an anesthetic like ether or chloroform. The treatment is usually painless and the complications few if the case is handled properly. The disadvantages are that, in a few instances, the treatment may be a little prolonged, and when the piles are greatly thickened and fibrous they do not completely disappear. For these cases Martin usually employs the ligature, operating under local anesthesia. The complications, such as pain, hemorrhage and strangulation, can be avoided by performing a free divulsion of the sphincter muscles under nitrous oxid anesthesia. This anesthetic is quick, safe and non-irritant, and the patient need not be confined to bed after the operation. About four days after divulsion, or when the primary sorenes has subsided, the treatment by injection may be commenced. Martin employs a 50 per cent. solution of phenol, injecting from 7 m. to 10 m. of this solution directly into the center of the pile. The injection is made through a conical speculum, care being taken first to swab off the surface of the pile with an antiseptic solution. The speculum is then withdrawn, allowing the rectal walls to collapse, after which the syringe may be removed. After introducing a suppository containing 3 m. of ichthyol the patient may return to his usual occupation. These suppositories are also used twice daily—one after stool and one at bedtime. Treatments should be given at intervals of from two to seven days and should be continued until all the hemorrhoidal masses have disappeared. Martin says that the method, if properly used, is perfectly safe; when it fails to cure no harm has been done, and one of the other operative methods may be tried.

4. **Disinfection of Dwelling Houses and Bedding.**—Stewart has devised an apparatus for the disinfection of dwelling houses and bedding. The apparatus consists of a tank made of heavy brass, 18 inches high and 8 inches in diameter. An air-pump attached to the side furnishes the air pressure and in this position also prevents the squirting of formalin solution into the face of the operator. There is no rubber hose on the machine and no rubber gaskets; the rubber tube generally used being supplanted by an ordinary gas bracket with two joints, which can be set in any position so that the operator can remain in an erect posture at all times. The stream of formalin is broken up by a whirling device at the extremity of the gas bracket. A continuous fine spray without the mixture of air can be thrown easily at a distance of from ten to twenty feet, allowing the operator to cover the surface of the room before the gas becomes unbearable. When loaded with two gallons of solution the weight of the machine is twenty-five pounds. About 500 square feet of surface can be gone over in three minutes. With a 5 per cent. solution of formaldehyd gas a series of 2,000 tests showed 97 per cent. of surface disinfection. The results were equally gratifying from a series of experiments to test the value of this method in the disinfection of bedding.

5. **Purpura Hemorrhagica During Pregnancy.**—Van Sweringen reports a case of purpura in a young woman of 25, which appeared in the fifth month of her first pregnancy. Hemorrhages occurred from the gums and nose, into the cellular tissue and skin, and appeared in the urine and vaginal discharge. From none of these localities was the bleeding very profuse or serious at any one time. Continuing, however, over a period of two or three weeks, considerable anemia was produced and the prognosis was rendered unfavorable. The hemorrhagic tendency subsided, however, the pregnancy went to term, the delivery was accomplished by forceps and was followed by no unusual hemorrhage, the puerperium being perfectly satisfactory. The treatment adopted consisted of rest in bed, 5-grain doses of calcium chlorid with 1 grain of extract of suprarenal gland every three hours and gelatin *ad libitum.* Several cervical cauterizations in the early months of pregnancy, done to relieve the severe nausea and vomiting, are looked on as possible causes of the condition because of the purulent discharge which followed. Absorption of infectious material from the cauterized areas seems probable, although no leucocytosis was present.

7 Differential Diagnosis of Ectopic Gestation. B. H. Wells, New York.
8 *Facts Concerning the Early Diagnosis of Pulmonary Tuberculosis. J. H. Pryor, Saranac Lake, N. Y.
9 *Submucous Resection Operation for Deviation of the Nasal Septum; with Description of Several New Instruments. L. M. Hurd, New York.
10 Conservative Gynecology. C. G. Cumston, Boston, Mass.
11 *Tryon, N. C., as a Climatic Resort. H. J. Garrigues, New York.

8. **Early Diagnosis of Pulmonary Tuberculosis.**—Pryor states that as the result of observation and experience gained while acting as the first medical superintendent of the New York State Hospital for the Treatment of Incipent Tuberculosis, his conviction that pulmonary tuberculosis is rarely recognized at an early and proper time for successful treatment, has been decidedly strengthened. This conclusion is corroborated by the fact that the hospital, which was created under a law providing that only incipient cases could be admitted, has never contained more than one-third of the number of cases that could be accommodated. Inquiries submitted to a number of sanatoria in the United States to learn the percentage of incipient cases received, as thus defined, reveal the fact that the average percentage of all patients under treatment which could be designated as early and favorable varies from 2 to 30. An analysis of all cases treated at the New York State Hospital shows that 60 per cent. were received. In attempting to account for this state of affairs Pryor says that one reason is that the patient does not seek medical advice early enough. This is especially the case among the poor, who also often receive incompetent counsel when they do go to a physician or dispensary. Other reasons are the faulty education in medical schools and the recent tendency to give prominence to laboratory methods at the expense of the skill of the clinician. The classical symptoms almost invariably presented in combination, are loss of appetite, chlorosis or anemia, loss of weight, cough, with or without expectoration, hemorrhage, and fever. It is extremely rare that all of these are associated at an early time. They are apt to be present at a later stage. This is particularly true of patients who have had rest, nourishing diet, and open-air treatment. Many times, under these conditions, few or no symptoms are apparent, and yet the disease may be progressive. The author also discusses at length the physicial examination of the chest and points out the necessity for painstaking examination of the patient with clothing removed to the waist.

9. **Submucous Resection for Deviation of Nasal Septum.**—Hurd describes this operation, which he considers preferable to the older methods used for correcting deviations of the septum. The procedure consists in incising the mucous membrane over the deviation in a curve with the concavity backward. The flap of mucous membrane and perichondrium is elevated and the cartilage is scratched through with a curette until the mucous membrane of the other side is reached. This layer is then also separated from the septum and the portion of the latter forming the projection is excised with Ballenger's swivel knife. If bone must be removed the author's special down-cutting forceps is used. The mucous flaps are allowed to fall together and are kept in opposition for a few days by light packing. Hurd pays great attention to securing proper cocainization of the parts, and states that the operation may take from ten minutes to an hour. Several of the special instruments invented by Hurd are described and illustrated.

11. **New Climatic Resort.**—Garrigues praises Tryon, N. C., very highly as a resort for rheumatic and gouty people, convalescents after serious diseases or operations, anemic persons, those affected with tuberculosis, heart disease, or any ailment of the respiratory tract. Tryon is situated in the western part of North Carolina, at the foot of the steep slope forming the connection betwen the mountainous region and the lowland, slightly above the thirty-fifth degree of north latitude, at an altitude varying from 1,000 to 1,200 feet above sea level, and about 250 miles from the Atlantic. The weather is mild and dry without extremes of temperature, winter or summer, and the author believes it is the best all-year-round climate in the United States. The annual number of sunny days is very large, drainage is perfect, and mosquitoes are rare. It can be

reached from New York in twenty-five hours, with one change of cars.

13 *Simple Method of Measuring and Graphically Plotting Spinal Curvature and Other Asymmetries by Means of a New Direct-Reading Scoliometer. G. W. Fitz, Boston.
14 The City Physician, His Duties and Responsibilities. J. H. McCollom, Boston.

13. **New Direct-Reading Scoliometer.**—Fitz sets forth a method which he considers practical, simple, accurate and inexpensive, by which definite measurements can be made. The apparatus employed comprises: 1. A scoliometer consisting of a sheet of transparent celluloid 2/100 inches in thickness and 52 cm. long, by as great a breadth as is desired, a convenient breadth being 16 cm., with rectangular graduations and with two level glasses set at right angles to each other for determining the level of both the horizontal and vertical lines of graduation. The longitudinal graduations are 1 cm. apart and every second one has waterproof black ink run into the line to facilitate the measuring. The cross lines, which are 3 cm. apart, also may be inked, but ordinarily it is not necessary. A small level glass (A), the tube of which is bent to the curve of a circle of 12-inch radius, is fastened on the lower part of the sheet at exact right angles to the longitudinal lines, so that when the bubble is on its index these lines are exactly vertical. Another similar level glass (B) is fastened in like manner on the central part of the sheet and adjusted so that when the bubble is at the index the longitudinal lines are horizontal and the cross lines vertical. 2. A black flesh pencil for making the spinous processes of the vertebra, anterior superior spines, clavicles, scapula and such other points as it is desired to measure for record. 3. Card catalogue cards of such size and graduation as desired, for recording and plotting. The method of application of the scoliometer is as follows: 1. To measure deviation of the spine the patient stands on a chair or platform about sixteen to twenty inches in height; the tins of the spinous processes of the vertebræ, the posterior superior spines, the spines and lower angles of the scapula are spotted with the flesh pencil. The scoliometer is then placed on the back in such a way as to bring the zero point of the longitudinal scale to the tip of the seventh cervical vertebra, and to bring the lower end of the midvertical line to the cleft of the buttocks. The middle line of the scoliometer then corresponds with the line of the spine, provided the latter is normal. If abnormal, the amount of lateral deviation from the median line is measured directly in the following manner: Looking at the back through the scoliometer and keeping the eye well away from the latter (about two feet), with the line of vision approximately perpendicular to the plane of the scoliometer at the point where the measurement is being made, the graduations of the scoliometer projected on the back of the subject are seen, and the amount of the deviation from the median line is shown in centimeters and fractions. The vertical distance is read and recorded downward from the zero point on the seventh cervical spine to the successive distances, and the amount of lateral deviation of the spine from the median line is noted at each of these successive points (or such of them as are necessary to define the curve). 2. To measure the lateral deviation at the spine with reference to a true vertical midline, the scoliometer is placed on the back of the patient with the zero of the seventh cervical process, the bubble of level A being at its index; the lines of the scoliometer are vertical and the measurement can be carried out as above. This is usually a more significant measurement, since it measures lateral posture as well as deformity. 3. The lateral contour of the trunk, if desired, may be measured, recorded and plotted by the scoliometer in like manner, either by having the scoliometer broad enough to include the entire trunk or by shifting the median line of the narrower scoliometer a measured distance to each side of the median position recorded as above and then measuring the deviations of the side contours and plotting them in their proper relation to the median curve. 4. To measure the lateral displacement of the shoulders in relation to the pelvis the zero point of the scoliometer is placed on the tip of the seventh cervical spine; the scoliometer is swung to the vertical position; the latter distance of the lower end of the median line is read off from the cleft of the buttocks, and recorded as displacement of shoulders to right or left of pelvis. 5. The lateral tilt of the pelvis, due to a short leg, to congenital deformity, or to functional shortening through flattening of the arch of one foot or relaxation of knee when bearing weight, may be measured by spotting the anterior superior iliac spines with the flesh pencil and then applying the scoliometer so that the longitudinal lines are horizontal as determined by level B; if the zero line is then adjusted to one of the anterior superior spines the relation of the other to it is determined and any tilting present is discovered and measured. 6. By holding the scoliometer at the side of the patient it is possible to measure and to record antero-posterior curves with a fair degree of satisfaction in many cases, though the apparatus is not especially adapted to this purpose. 7. With the scoliometer in a horizontal position the difference in levels of shoulders can be instantly measured. The observer should stand in front of the subject. A number of other applications of the scoliometer are feasible as, for example, measuring the lateral or antero-posterior deviation of the head, the level of the eyes, and the horizontal and vertical position of the arms.

20 A Phase of the Yellow Fever. L. O'Connell, Washington, D. C.

15. **Treatment of Bronchitis in Children.**—Winters says that the treatment of bronchitis in children necessitates intimate acquaintance with the structure of the bronchi, and with every alteration in this structure at each step and every hour of the morbid process. The child should be placed in a crib—never on a bed. The crib should be flannel lined and should be in the center of the room—never near a wall, window or door. Sometimes it becomes necessary to place screens about the crib to avoid draught. Light flannel should envelop the child's body, arms and legs. This, says Winters, comprises nine-tenths of the treatment to be adopted in a case of moderate severity. In severe cases the drug recommended by him is aconite, to be given in water only, in small (less than one drop) doses, repeated often. Intestinal elimination, diaphoresis, aconite and sweet spirits of niter are the febrifuge measures employed by Winters. Coal-tar derivatives he considers contraindicated. Cold applied to the cutaneous capillaries he says is unphysiologic, pernicious and conducive to extension. It is wrong to give stimulating expectorants. When the secretion becomes excessive, the child should be kept in the prone position to secure gravitation of the secretions. Emetics may be given. Oxygen inhalations should be continuous—even during sleep. These measures Winters supplements with mustard packs and maximum doses of spirits of camphor and carbonate of ammonia. He has found castor oil, in 10-minim doses a most efficient remedy for the harassing cough in inflammation of the upper respiratory passages. In older children in whom the irritation of coughing superinduces nervous irritability, small doses of codein may be given. [*This drug should be used cautiously in children.*—Ed.] He discountenances the use of steam inhalations on the ground that they increase the susceptibility to cold, to catarrh of the larynx and bronchi—catarrhal croup.

16. **Determination of Abdominal Rigidity.**—The instrument devised by Kilmer apparently is identical with the one invented by H. A. Kelly of Baltimore, and described in the *Johns Hopkins Hospital Bulletin* of September, 1904. Kelly called his instrument a piezometer.

24. **Scopolamin-Morphin Chloroform Anesthesia.**—Isham recommends the injection of scopolamin hydrobromid 1/100 gr. and morphin hydrochlorid 1/6 gr., preliminary to operations requiring a long anesthesia, and also even before short operations when the patients are very nervous, excitable, and either suffering great pain before, or liable to suffer after the operation. The literature is reviewed and additional cases are cited.

25. **Scopolamin as Anesthetic.**—Sharp says that if scopolamin deserves a place among anesthetics it is without doubt in combination with chloroform. The inconstancy of its action renders it impracticable when used alone or with morphin. In fact, continues Sharp, it is doubtful if it would ever produce anesthesia when given alone on account of the extreme restlessness which is present unless morphin is given. While scopolamin may not prove to be the ideal anesthetic, it is without doubt worthy of further investigation, and Sharp believes that with improved technic it will show itself to be an improvement over the present methods. The method of procedure adopted in 3 cases is described in detail.

33 Pathology of Yellow Fever. P. L. Pothier.
34 *Treatment of Yellow Fever. L. F. Solomon.

34. **Treatment of Yellow Fever.**—Solomon asserts that no one stricken with yellow fever should die unless there existed, previously, disease of the heart or of the kidney. He outlines his treatment as follows: The first step necessary is the administration of a large saline purgative, preferably sodium sulphate. This thoroughly cleanses the entire intestinal tract. It is not necessary to give calomel or any purgative, because the sodium sulphate, in addition to its flushing power, also acts as a cholagogue. Often when the patient is seized with the attack there is undigested food in the stomach. If this occurs a short time after eating the patient will vomit and empty the stomach of food. If the seizure comes on three or four hours after a meal, and there is still some undigested food in the stomach, there will be nausea. In such cases Solomon states that it is well to give minute doses of calomel for the purpose of quieting the stomach, so that the sodium sulphate will not be rejected. For this purpose the following combination is the best adapted to the purpose: A powder consisting of 1/4 grain of calomel with 1 grain of ingluvin. This is to be repeated every twenty minutes until four are taken, and then followed in half an hour with one-half or one ounce of sodium sulphate dissolved in a glassful of water. Very frequently the intense headache accompanying the onset of the attack will be relieved after the administration of the saline. If not, relief can be obtained by the old-time hot footbath. One hour after the administration of the purgative, and without necessarily waiting for its action, Solomon begins the administration of the following prescription:

℞.	Potassi nitratis........................	ʒi	4
	Liq. ammoniæ acetatis..............	℥iiiss	105
	Syr. aurant. flor........................	ʒiv	16

The adult dose of this mixture is half an ounce, repeated every two hours during the continuance of the fever. The liquor ammoniæ acetatis is administered in conjunction with the potassium salt for its action on the skin, as it causes free diaphoresis, thus favoring elimination. The potassium nitrate in addition to its specific effect as on antitoxin, also acts as a prophylactic diuretic. Within a few hours after beginning the administration of the above mixture the temperature, no matter how high at the outset, will begin to decline and will decline progressively until the end of the third day, when convalescence will begin.

40 Infant Mortality in Michigan and Detroit, with an Inquiry Concerning a Normal Infant Mortality. H. M. Rich, Detroit.
41 Starvation Diet. E. L. Coolidge, New York.

35. **Stenosis of the Pylorus.**—Griffith reports a case of this kind occurring in an infant on the sixteenth day after birth, the obstruction evidently being chiefly spasmodic, although the obstruction was probably increased by the swelling of the mucous membrane caused by the irritated state of the whole gastrointestinal tract. The child was treated symptomatically and made an uneventful recovery.

36. **Id.**—Rotch and Ladd report 2 cases. One patient was three weeks old. A diagnosis of pyloric stenosis was made from the clinical picture and immediate operation advised. On opening the abdomen the stomach was found dilated to about the size seen in a normal infant of three months, and at the pylorus was situated an oval solid tumor approximately ¾x⅜ inches in diameter. A posterior gastroenterostomy was made with clamps and suture, a jejunal loop being used. The child recovered from the operation, and one year later was in good health and of normal development. The second patient was four weeks old. The pylorus was firm, making a mass about one inch long by three-eighths of an inch in diameter. The obstruction was complete. The lowest anterior portion of the stomach was withdrawn from the abdomen and seized with clamps; the jejunum being too small to clamp, was seized with hemostatic forceps, at a portion farthest from the mesentery, and approximated to the stomach. A running stitch, including the peritoneum and muscles, was carried along the posterior approximated surfaces. An elliptical piece of the stomach was incised and a longitudinal slit was made, cutting the duodenum in front of this stitch; a continuous silk stitch was carried around, uniting these openings, and passing through all the layers. The posterior stitch was then continued around through the serous and muscular coats, in front of the deep layer of stitches and tied at the starting point. The clamp and walling-off gauze were then removed and the area washed with salt solution. The stomach and the jejunum were returned to the abdomen. The omentum was tucked around the area. The incision was then closed with interrupted silkworm stitches through the entire abdominal wall. The patient died on the fourth day after the operation from exhaustion.

37. **Leucocyte Counts in Pneumonias of Children.**—Leucocyte counts were made by Heiman in 19 cases of bronchopneumonia occurring in children from 10 months to 5½ years. The highest leucocyte count taken during the height of the illness was 73,000; the lowest, 12,600. There were 12 recoveries and 7 deaths. In the former all the counts during the first few days of the illness were high, while toward the end of the illness the counts were low except in two cases, one being complicated by mastoiditis and the other by tonsillitis. All the 7 fatal cases gave high counts early in the disease; shortly before death the counts in 4 of these cases were markedly diminished, while they remained high in 3 cases. Heiman also studied 24 cases of lobar pneumonia occurring in children varying in age from 2½ to 9 years. The highest count, while the pneumonia was active, was 55,800; the lowest, excluding a post-typhoid case and a case of pleurisy, was 20,200. There were only 2 fatal cases, and in both a well-marked leucocytosis was present during the height of the disease, while just before death a marked drop in the leucocyte count was noted. In 7 cases of empyema studied there was a marked leucocyto-

sis at the onset. There were 6 recoveries and 1 death; the fatal case gave the highest blood count at the onset of the disease and the highest terminal count. Heiman found that the leucocytosis in the bronchopneumonia is independent of the amount of lung involved, nor does the degree of leucocytosis stand in any relation to the height of the temperature. Though there are some exceptions, the general rule in bronchopneumonia is that failure of the leucocyte count to drop when the pulmonary signs disappear indicates either a complication or a fatal termination of the illness. A constant and considerable leucocytosis may regularly be expected in the lobar pneumonia of children. The degree of leucocytosis is about the same as in bronchopneumonia, but differs in that the white count is higher when the pulmonary involvement is greater. An increasing leucocytosis is the general rule in the lobar pneumonia of children, reaching the maximum just before the crisis. While failure to drop before the crisis may indicate a complication, yet this may be of no special significance. In general, Heiman says, the diagnostic value of the leucocytosis in the pulmonary affections of children is limited. In certain instances, however, the leucocyte count is of great diagnostic aid. When, for example, in lobar pneumonia, resolution and the drop in the leucocytosis has occurred, and there are present signs exciting suspicion that empyema will be a sequel, blood counts should be made frequently at regular intervals. A sharp rise in the count, provided that other causes of leucocytosis can be excluded, is then strong presumptive evidence of a supervening empyema.

39. **Infection in Scarlet Fever.**—Herrmann summarizes his paper as follows: 1. Cases of scarlatinal infection through open wounds have the following characteristics—(a) the period of incubation is short; (b) there is a characteristic change in the appearance of the wound following infection; (c) the neighboring lymph nodes become enlarged; (d) the rash usually (but not necessarily) begins at the point of inoculation; (e) the throat symptoms are mild, there is no exudate or marked involvement of the submaxillary glands; (f) after the rash has reached its height the wound improves rapidly in appearance; (g) desquamation usually (but not necessarily) begins around the wound. 2. Extrabuccal infection with scarlet fever is probably more frequent than is generally supposed. It should be looked for in cases in which (a) the period of incubation is unusually short; (b) those in which the throat symptoms are slight; (c) cases in which the rash makes its first appearance in an unusual location. 3. All children exposed to scarlatinal infection should have open wounds (including vaccination) covered by a protective dressing. 4. The period of incubation in scarlet fever depends on (a) the virulence of the contagious material; (b) the receptivity of the individual; (c) the portal of entry of the infectious material. 5. An individual who is immune to infection in the ordinary way may contract the disease by direct inoculation.

44 Clinical Aspect and Treatment of Pompholyx. F. J. Leviseur, New York.
45 *Mycosis Fungoides and the X-ray. A. J. Markley, Cincinnati, Ohio.

43. **Tricophytosis.**—Wallis cites 10 cases occurring in girls ranging in age from 8 to 17 years. In each case pediculosis was present, and in nearly every instance an existing cutaneous eruption was attributed originally to the pediculosis, which was later shown to be erroneous. The clinical appearance presented was similar in each case of the series; the primary folliculitis followed by pustulation, then by rupture and scar formation with temporary alopecia, followed by restoration of hair, the cycle being repeated in many instances. Particularly characteristic was the recurrence of the lesions on sites of previous lesions. Another feature especially distinctive was the appearance of the black dots at the margins of the lesions, representing the broken-off stumps of diseased hairs. Microscopic examination of the hairs and cultures taken from them demonstrated the presence of ringworm fungus. The microscopic examination, the growth in cultures and the complete recovery without the destruction of hair follicles, producing permanent baldness, is conspicuous. Wallis concludes, in view of these histories and observations, that these were cases of an unusual type of tricophytosis previously neglected and unrecognized by reason of the associated pediculosis capitis. This series of cases also serves to emphasize the necessity of careful microscopic examination in all scalp conditions.

45. **X-Ray in Mycosis Fungoides.**—Speaking of the treatment of mycosis fungoides, Markley says that in the *x*-ray we possess the most active agent for relieving the tortures and symptoms of this hitherto incurable disease. The history of one case is cited in which the affection involved practically the entire body. The treatment with the *x*-ray was begun at once, using a soft tube at a distance of eight inches, exposing each area five minutes, making about twelve different exposures at each seance and two seances a week at first. In addition, mild and soothing antipruritic lotions were prescribed. At the end of six weeks practically all the patches had disappeared, and the skin was soft and smooth but very deeply pigmented. The general condition of the patient improved rapidly, as did also her appearance.

49 Anesthesia Associated with Hyperalgesia Sharply Confined to Areola-Nipple Area of Both Breasts, A New and Apparently Constant Stigma in Hysteria. W. W. Graves, St. Louis.

48. **Acute Anterior Poliomyelitis.**—Hoch holds that anterior poliomyelitis is the result of a primary inflammatory disease of the blood vessels of the cord which may be thrombotic or embolic. The destruction of the ganglion cells is secondary and depends in part on the deficient blood supply of the diseased area and in part on pressure and toxins. The pathologic changes occurring in poliomyelitis of children and adults are apparently identical and dependent on similar causes. There is sufficient evidence at hand to consider the disease as a rule of an infectious nature, not depending, however, on a specific micro-organism, but resulting from bacterial infections of various kinds and at times from other poisons. The inflammatory changes are present in the peripheral vessels as well as in the branches of the anterior spinal artery, though these changes are seldom visible until the vessels enter the gray matter. The inadequate collateral circulation within the anterior horns is favorable for sluggish circulation and embolism.

50 Treatment of the Acidosic and Sugar States from Traumatism. G. F. Butler, Chicago.
51 *Clinical Study of the Diagnosis of Urinary Calculus. B. Lewis, St. Louis.

51. **Diagnosis of Urinary Calculus.**—Speaking of the value of the Roentgen ray in the diagnosis of urinary calculi, Lewis says that the examination is painless, requiring neither local nor general anesthesia. There is no danger from traumatism or infection, and the danger from burn is practically *nil*. Not only does the skiagraph show the exact location of the stone, it also shows the number of stones present. It does away with the necessity of doing an exploratory operation for diagnostic purposes. It differentiates calculous nephritis from other conditions in neighboring organs, and the negative diagnosis is as accurate as the positive, except in very stout patients. The percentage of error in all cases skiagraphed has been less than 3 per cent., and in the majority of cases in which there were erroneous negative diagnoses the calculi were so small that they passed without surgical interference.

56 V[illegible] of Uterus. C. W. Hibbitt, Louisville.

55. Jequerity and Trachoma.—Taylor uses jequerity in trachoma. The infusion, tincture or powder may be used. Taylor prefers the impalpable powder, which he dusts lightly on the everted lid. The eye is then closed for two or three hours with a light bandage. The application is always attended with severe pain, which usually becomes intense from three to five hours after the application. Swelling of the lids often occurs, and often extends to the forehead, cheek and nose, and sometimes the lips are swollen. Escharotics, silver nitrate, sulphate of copper, etc., with rollers, may be used in conjunction with jequerity, but the escharotics will produce greater destruction of normal tissue than the jequerity. Taylor has never lost an eye from the use of jequerity, but has had the swelling assume alarming proportions, and for this reason he never applies the powder until the patient is in an infirmary where the swelling can be best controlled. Out of 73 cases, in not a single instance has the result been disappointing, the patients being discharged in from six weeks to three months. Twenty-two cases were placed in the infirmary the second time from four to eight months after the first treatment and jequerity applied again with complete relief. [The United States Dispensatory states that according to de Wecker the cold infusion, one part to twenty, has been used in chronic granular conjunctivitis, but is much too strong and is liable to set up violent conjunctivitis or keratitis.—Ed.]

62 Combined Malignant Tumors of the Female Genitalia. P. Findley, Chicago.

57. Establishment of Cerebral Hernia for Inaccessible Brain Tumors.—Cushing states that inasmuch as the symptoms accompanying brain tumor are due to the pressure effects of a slowly enlarging foreign body, it should be possible to relieve them by allowing the compressed brain to protrude through an artificial opening in the skull. In younger individuals this may occur through separation of the already fused sutures. Cushing has seen three instances of this kind. He says it would be a mechanically ideal treatment for cases of inaccessible tumor if in adult life it were possible to bring about such a dislocation of the sutures in the cranial vault. As this can not be done, recourse must be had to decompressive methods which are less perfect inasmuch as they do not so evenly distribute the compression. In order to control the growth of the cerebral hernia Cushing now makes the bone defect under the temporal muscle. The advantages are many. An oval opening may easily be made, about five or six by eight or ten cm. in its two diameters without freeing the muscular insertion at the temporal ridge. Being in a comparatively thin and relatively non-vascular portion of the skull, the bone is easily rongeured away and the opening on one side alone is usually sufficient for decompressive purposes. Should it prove not to be, a bilateral operation of the same kind may be made. The denuded area of the cortex exposes, for the most part, the convolutions below the fissure of Sylvius, including only the very lowest part of the motor strip, so that, even in cases of extreme unilateral bulging, the greatest harm that would ensue would be from an implication of the center for the tongue, jaw and lower part of the face on the one side. The incision is entirely within the hair margin, and the degree of protrusion that may take place under the protection of the muscle may not be at all obtrusive. Cushing states that the results obtained by this method, which is described in full, have been most gratifying.

60. Echinococcus Disease of the Heart.—Grulee believes that his case was probably one of primary echinococcus disease of the heart with secondary infection of the lung. This is suggested (1) by the diffuse infection of the latter; (2) by the peripheral location of the cysts in the lungs; (3) by the intimate connection of certain of the cysts with pulmonary vessels; (4) by the presence of daughter cysts in a cyst located in the right auricle, and (5) by the fact that an existing pulmonary tuberculosis was all on the right side, while the echinococcus cysts were about equally distributed between the two lungs. No trace of the echinococcus disease was seen in any other organs than the lung and heart.

63. Uterine Curettage.—Montgomery says that uterine curettement is so pregnant with disastrous possibilities that it should only be essayed by one who is so skilled and trained in aseptic methods that he can protect his patient from danger of infection. The procedure in the most careful hands may be attended with perforation of a softened uterine wall. The occurrence of perforation does not of itself demand an abdominal section for closure of the opening, for in the great majority of such injuries the patients recover without any serious symptoms, but in case of injury of intestine from perforation and the dragging of a loop of intestine through the opening, or in the presence of sepsis, the peritoneal cavity should be opened by abdominal section in the first instance, and the injured intestine treated by suture or excision, as the lesion may demand, while in the second instance the section may be either abdominal or vaginal, as operator elects.

2. **Conception of Disease.**—Treves attempts to show that there is nothing preternatural in disease, that its phenomena or symptoms are marked by a purpose, and that that purpose is beneficent; that the processes of disease are aimed not at the destruction of life, but at the saving of it, and that its manifestations are the outcome of a natural effort for cure. He says that disease, as popularly realized, is not one of the ills that flesh is heir to, but one of the good gifts, for its motive is benevolent and protective. He says that he can not express this more concisely than by saying that if it were not for disease, in the popular sense, the human race would soon be extinct. A case is cited illustrating the beneficent effect of the inflammatory reaction which occurs following trauma. To the layman this suggests disease, when in reality the trauma probably would encompass the death of the patient if it were not for this inflammatory reaction. The inflammation which is dreaded so much by the laity is a benevolent process with one purpose, that of protecting the body, and one aim, that of cure. Without the protection of inflammation, says Treves, the human race could hardly survive a month. When inflammation does supervene, therefore, it is the surgeon's part to make it as tolerable to the patient as possible, and as soon as it becomes evident that Nature is intending to throw certain matters from the system, the surgeon, acting on that hint, opens an abscess or incises a tense swelling. He who grumbles about his cold, says Treves, is finding fault with a measure of relief to which he owes his life. What the patient may justly grumble at is the undoubted misfortune that he is the subject of bacterial infection, and he may also, with reason, complain of the discomfort incident to being poisoned; but it is hard to blame Nature for successfully defending him against the effects of this casualty. Methods of treatment whether carried out by Nature or by art, are seldom pleasant, but they are not blameworthy. The symptoms of a malady are in reality the expressions of a desperate attempt on the part of the body to fight the exciting cause of that malady. According to this conception Treves refers to appendicitis, malaria, Malta fever, diphtheria, tuberculosis and bubonic plague. Speaking of cancer, Treves speculates as to whether or not extracts or active principles taken from the glands that are active during the period of development in children, such as the thymus, would exert an influence late in life which they seem to be intended to exert when growth is alert in the young. He wonders whether or not the introduction of the active principle of such a gland in a case of cancer would cause a disappearance of the tumor.

3. **Intramuscular Injection of Mercury in Syphilis.**—In all, 3,230 patients with syphilis were treated by Lambkin by the intramuscular method. They represented syphilis in all its various forms—slight primary abrasion, with indurated inguinal and cervical glands, followed by a roseolar rash; true Hunterian chancre, with glandular enlargements, followed by various rashes, papular, psoriatic, pustular, etc.; phagedenic chancre, rapidly destroying tissue, accompanied or followed by rupial and serpiginous ulceration, causing destruction to both soft and hard parts; the later sequelæ of syphilis being represented by paralysis, both local and general, from cerebral and spinal lesions, and also by many cases of tabes of undoubted syphilitic origin. The treatment necessitated some 60,000 intramuscular injections. Of this number about 10,000 consisted of injections of the soluble salts—calomel and the salicylate of mercury. The remainder—that is, 50,000—was made up of injections of metallic mercury. Most of these patients have been lost sight of, but 30 or 40, with whom Lambkin has been in touch for 10 or 15 years, have since married; none of them has had any return of the disease, nor has the offspring borne traces of hereditary taint. No injections were followed by abscess, nor by embolism or severe stomatitis. On the whole, he says, the success which he has obtained from the intramuscular method of treating syphilis is out of all proportion to that which was obtained in days gone by when using older methods. The remainder of the patients (230) were treated in the last four months. They have all done well.

6. **Splenic Anemia.**—Bassett-Smith, in an attempt to establish a relationship between splenic anemia and affections in which the Leishman-Donovan bodies are found, investigated 2 cases. As a result of these observations he concludes that splenic anemia is not due to any parasite, but belongs to that class of cases which come under the term of "tropical splenomegaly" in which the Leishman-Donovan bodies play an important rôle.

10. **Pinta.**—Under this name Sandwith describes a tropical disease caused by a fungus which produces various discolorations on the uncovered parts of the skin and sometimes on the mucous membranes. It is also known as spotted sickness and *le caraté.* Dirt and poverty seem to be predisposing causes. The exciting cause is the *Trichophyton pictor* which produces what may be called an aspergillosis of the skin.

12. **Pellagra.**—Sambon calls attention to many analogies between pellagra and some of the protozoal diseases, and suggests that study of the prevention of pellagra be made in the direction of its being caused by an animal parasite.

16. **Tropical Skin Disease.**—The disease described by Bell occurs in the form of a large circular patch on the side of the foot, about the size of the palm of the hand, red and irritable in the center, with circular edges undermined, and burrowed in places. It is caused by the *Rhizoglyphus parasiticus.* Treatment with 4 per cent. formalin in glycerin produces immediate results.

18. **Involvement of Scalp in Leprosy.**—Pernet cites 2 cases in nodular leprosy in which the scalp was involved. The diagnosis of the infiltrations of the scalp rested on clinical grounds alone, but Pernet is convinced of its correctness. There was no certain basis on which to make a diagnosis of syphilis.

20. **Diarrhea from Flagellates.**—Castellani reports 2 cases of severe diarrhea caused by several varieties of flagellates, such as the trichomonata, cercomonata, *Entamœba undulans* and the *Lamblia intestinalis.* The affection yielded to the injection of a solution of methylene blue, using three pints at a time.

23. **Quinin Prophylaxis of Malaria.**—The method of taking quinin recommended by Gray is based (a) on the fact that the life cycle of the parasites is nearly always forty-eight hours, and (b) that eight or ten days must elapse after infection before they become sufficiently numerous in the blood to cause an attack of fever. Hence it follows, says Gray, that if

a full dose of quinin (10 or 15 gr.) be taken on two successive days, with an interval of eight or nine days before the next two doses are taken, the parasites will always be destroyed before they can cause fever. The method has proved as efficacious as the five-grain-a-day plan, with the advantages that there is one week when the individual is not taking any quinin at all (which is fully appreciated by those who are susceptible to the unpleasant effects of the drug) and less than half the quantity is used.

35 Epidemic of Dysenteric Diarrhea. T. Orr.
36 Ready Method of Differentiating Streptococci and Some Results Already Obtained by Its Application. M. H. Gordon.

29. **Parathyroids in Exophthalmic Goiter.**—Humphry urges that in fatal cases of exophthalmic goiter, of myxedema, of tetany in children, and in cases of death following operations on the thyroid gland, the parathyroids should be examined carefully, for the purpose of ascertaining whether or not there is evidence of any pathologic change. In 2 cases of exophthalmic goiter examined, Humphry found that in the parathyroids there were gross changes consisting of extensive infiltration of fat between the columns of gland cells; in fact, the gland tissue was largely replaced by fat. In two other cases the same process was found, but only in the beginning stages. Humphry also examined the parathyroids microscopically in 18 cases of death from various causes—namely, accident, tubercle, pneumonia, Addison's disease, bulbar paralysis, Bright's disease, diabetes, leukemia, cancer, convulsions and old age. The ages of the patients were from 1 year to 71 years; 12 were female and 6 were male. Twelve were between the ages of 1 and 50 years; the parathyroid glands in these appeared normal, with the exception of one. The gland tissue was compact and practically free from the infiltration of fat; the arrangement of the cells showed instances of the different types of gland tissue. The one exception was from a girl, aged 14 years, who died from burns. The parathyroid in her case showed some excess of fat and she was found to have an enlarged thymus weighing 18 grams. The thyroid appeared to be normal, but was not examined microscopically. Of 6 patients whose ages were from 50 to 72 years, 4 showed well-marked fatty infiltration of the parathyroids; the one most affected was from a case of diabetic coma in a man aged 60. Humphry suggests that the parathyroid gland may have an important function to perform, one that is independent of the thyroid function, and that disturbance of this function may stand in some relationship to the various diseases investigated, especially exophthalmic goiter.

32. **Caffein in Renal Dropsy.**—After all other methods to relieve the edema had failed, Rolleston and Attlee administered citrate of caffein, 7½ grains three times a day, for twenty-five days, when the dose was gradually diminished until it was discontinued entirely about eight days later. The effect of the caffein was manifested almost at once, the urine increasing in amount with a proportionate lessening and final disappearance of the edema.

34. **Twice Ruptured Tubal Pregnancy.**—Leicester cites this case to illustrate the difficulty of diagnosing a ruptured tubal pregnancy when the symptoms are vague and indefinite, pointing toward abdominal disease rather than to the actual condition.

42 Significance of the Pyriform and Globular Bodies Present in the Circulation and Organs in Various Forms of Disease. A. Lingard.

38. **Permanganate of Potash for Snakebite.**—Rogers treated 12 cases of snakebite with potassium permanganate, according to the method proposed by Lauder Brunton. In 4 cases the treatment was commenced at once; in 3 cases a full half-hour elapsed before it was commenced, but in two of these a ligature had been applied shortly after the infliction of the bite. In 3 other cases three-quarters of an hour, one hour and four hours respectively elapsed before treatment was begun, but it still proved successful in saving the life of the patient. Only 2 of the 12 patients died. In the majority of cases the snake inflicting the wound was a cobra. The 2 patients who died did not come for treatment until nine and eleven hours respectively after having been bitten.

43. **Albuminuria.**—Lancereau distinguishes three types of albuminuria, according to the epithelial, vascular or nervous origin. The prognosis varies with each type. It is very serious when the secreting epithelium of the kidney is destroyed, and favorable when the elements are still capable of recuperation. The prognosis is grave also in albuminuria of vascular origin, due to kidney lesions, with a constant and progressive tendency. Albuminuria of nervous origin scarcely modifies the general health; it is not accompanied by attacks of uremia, except under the rarest circumstances, and a complete cure may be obtained. Treatment should vary for these types. In the epithelial form it should be directed to restoring the epithelium to normal and to getting rid of the obstructing débris. After failure of other measures he has sometimes had the urine increase from a half pint to a quart or two quarts or more in 36 hours under the influence of from 6 to 10 drops of tincture of cantharides taken during the day in a mucilaginous julep. Raw milk also favors the diuresis in these conditions. In albuminuria of vascular origin, the aim is to act on the vessels, and the best remedy he has found to date for this purpose is from 1 to 3 gm. of sodium or potassium iodid in 24 hours. Milk is not so important here as in epithelial albuminuria, and need not be ordered except in case of an uremic attack. In albuminuria of nervous origin, the antispasmodic remedies are indicated, with hydrotherapy, an alcohol sponge on rising, and tepid, alternating hot and cold or even cold douches have proved beneficial in his experience. The diet is of importance, because there is generally dyspepsia in young and glycosuria in older subjects. He forbids wine and acids to the younger patients and puts the older ones on a diabetic diet, substituting potatoes for bread. His experience has been very gratifying with treatment along these lines, but in case of an attack of uremia he resorts at once to drastic diuretics and purgatives with the utmost energy, allowing no food but

milk sipped slowly every two hours, with tea and coffee if craved. In the nervous type of albuminuria, the amount of urine approximates normal, the tint is reddish or slightly yellowish. It never has the pale, skim-milk tint of the vascular type. The density ranges from 1015 to 1020, and it is not more abundant during the day than at night. The albumin precipitates in small flakes and may range from 0.5 to 2 or 3 gm. or more in the 24 hours. The albuminuria may be continuous or intermittent, orthostatic or cyclic. The general health is influenced but little. The microscope shows no casts nor epithelial cells in the urine, or, at most, only a few leucocytes and rare crystals of uric acid or calcium oxalate. This form of albuminuria is frequently associated with glycosuria, but the albuminuria does not continue a progressive course. It may cease abruptly or persist indefinitely. Generally curable and mild, this type of albuminuria still exposes, under certain conditions, to uremic accidents, as after getting chilled or exhausted or during the decline of some infectious disease. Energetic, appropriate treatment generally restores conditions to normal, but individuals presenting nervous albuminuria are, as a rule, less resistant to diseases than normal persons and succumb more readily, especially if they are at the same time glycosuric. Consequently their hygiene should always be supervised.

45. **Palpation Through Rectum in Urethritis.**—Lebreton presents numerous arguments to demonstrate that rectal palpation is one of the best, if not the best, means to detect a latent posterior urethritis. It is also an important therapeutic measure in this case, as massage and "expression" of the prostate, through the rectal walls, aid materially in the cure of lesions in this region. If the pressure of the finger on the prostate does not elicit pain, then massage should not be done, as the gland is yet sound. Massage is also contraindicated when the pressure is painful only along the median line, showing that the prostatic urethra is the only part involved. Massage under these conditions would only serve to spread inflammation to hitherto sound parts. On the other hand, massage is indicated whenever the lateral lobes are sensitive to pressure, regardless of the degree of painfulness. Massage should always be preceded by filling the bladder so that the liquid flowing out afterward will sweep out the débris resulting from the manipulations. In case of an actual abscess, massage is contraindicated until after the abscess has been evacuated, as it might induce perforation into the rectum or urethra. Evacuation through a transverse perineal incision is preferable, followed by massage.

55. **Intertesticular Anastomosis.**—Gatti says that degenerative processes follow when one testicle is grafted on the other, unless the manipulations have been extremely gentle. He has found it possible to make an anastomosis between the testicles after severing one vas deferens, thus insuring an outlet for its secretions. When this was done with the minimum of traumatism, the parts healed without degenerative processes and normal function was retained. There is only a very slight proliferation of connective tissue when the operation is done without resection of gland tissue. Anastomosis between the testicles should be advised in case of operative or traumatic lesions of the vas deferens of a sound testicle, but not after epididymectomy for tuberculous epididymitis. Gatti has had excellent results from this intertesticular anastomosis on dogs, and thinks that the conditions will prove much more favorable in man. He incises the tunica vaginalis and the tunica albuginea in the form of an X and then turns back the four triangular flaps made by this incision. The denuded surface of the two glands thus exposed by the turning back of the flaps is lightly freshened with a sharp knife, and they are held in contact with a stitch at each corner. The article is illustrated. (Mauclaire's experience in engrafting an atrophic testicle on its sound mate was mentioned in THE JOURNAL, 1903, page 62 of volume xl.)

Bulletin de l'Acad. de Médecine, Paris.

60 (Year LXIX, Nos. 33-34.) *Flies and Cholera.—Mouches et choléra. A. Chantemesse and F. Borel.

60. **Flies and Cholera.**—Chantemesse comments on the fact that more than a million and a half of victims have succumbed to cholera in the last four years. The disease spreads by transportation to long distances, by propagation from city to city and by dissemination from house to house, from individual to individual. Transportation of the contagion to long distances in merchandise is of such rare occurrence, he says, if it occurs at all, that prophylactic measures in this line would be worse than the danger to be feared. If the contagion could be transported in the goods and baggage of persons coming from infected countries, then the progress of cholera would have been entirely different. It would have followed the routes of navigation, and prophylactic disinfection, by the usual technic to date, would not have prevented this. The drinking water taken on board in an infected port would certainly infect the persons on the vessel during a long voyage if danger from this source were to be apprehended, but this is not the case. During the last four years the 4,000 ships returning from the Orient through the Suez Canal have brought 200,000 men in their crews and 500,000 passengers, and yet only 13 of the vessels have had cholera on board and only 29 persons were affected. Some of the persons were in the stage of incubation when they embarked, but in others the disease appeared from fifteen to thirty days after embarkation. These individual breakings out of the disease are extremely dangerous, and they are the only features to be feared in regard to the transportation of cholera to a distance. In one instance a ship from Java had a case thus break out twenty-nine days after leaving. If it had started from Bombay, the passengers would have been landed in France by the twentieth day, and the disease might thus have developed after the individual had been nine days on French soil. The maritime sanitary police are helpless in face of occurrences of this nature. The pathogenic microbes may lurk in the human organism without manifesting their presence. Gotschlich was sent, this summer, to Tor to examine the pilgrims returning from Mecca. Cholera did not make its appearance in Mecca this year, but he was ordered to examine the intestines of every pilgrim succumbing at Tor to any disease. He found cholera germs in several of the Russian and Turkish pilgrims from regions where cholera had been prevalent when they started on their pilgrimage. The identity of the cholera germs was confirmed by Gaffky, Köhler, Kolle and Meinicke, to whom they were sent for corroborative testimony. During the Mecca pilgrimage of 1905, no cases were observed which resembled cholera either clinically or in its pathologic anatomy, and yet several persons carried in their intestines for more than five months live cholera germs, capable of reproduction, and neither the bearers nor their neighbors developed cholera. The vibrios must have been very scanty or very much attenuated or a favorable opportunity for passing them to susceptible individuals must have been lacking. Recent data suggest that the limit of latent microbism of this kind is six or seven weeks at most. For this latent microbism to be still active after thirty days it seems to be necessary for the bearers of the bacilli to find some environment where filth or other conditions cause the revival of the attenuated microbes. Marseilles is only seventeen days from Bombay, and yet the town has never been infected by cholera arriving directly from India. Propagation of cholera from town to town is limited by the fact that three or four days of desiccation kill off the germs in baggage, clothing, etc. For this reason infected clothing arriving at Paris from India is not dangerous, while it would be extremely dangerous if it came from a town only a day's journey away. Flies can readily transmit the germs; their mouths, feet and intestines were found to harbor the vibrios in some tests which Chantemesse reports. Cholera is most fatal in the countries without sewerage, and it is there that flies most abound. The fly can not transport cholera to a distance nor propagate it from town to town, bnt it is a most powerful means of dissemination, and the dying down of epidemics in winter is due to the lesser number of flies. He concludes with the remark that in time of a cholera epidemic it might be well to placard the walls with the saying of an American writer: "It should be more of a disgrace for a housekeeper to have flies in her house than bedbugs in her beds."

Revue de Gynécologie, Paris.

Last indexed page 1367.

61 (IX, No. 5.) *Hystérectomie abdominale avec évidement pelvien et recherche des ganglions pour cancer de l'uterus. A. Pollosson (Lyons).

63 *Traitement de l'infection puerpérale grave par la laparotomie ou la colpotomie, sans hystérectomie. L. Sourdille.
64 De l'occlusion au niveau de l'angle colique gauche (left angle of colon). A. Nores (Cordova, Argentina).

61. Abdominal Hysterectomy for Cancer.—Pollosson relates the particulars of 32 cases of uterine cancer in which he operated by the abdominal route. He had previously preferred the vaginal route, but the ultimate results were unsatisfactory and he adopted Wertheim's technic. He removed the uterus and the tissues surrounding it in a single large mass. The ureters have to be detached from the mass first, and, when possible, transverse clamps should be applied to the vagina before cutting it. This prevents infection of the peritoneum. He gives the minute technical details of his operations and reviews the results. Several of his patients succumbed to intercurrent affections and a few did not survive the operation. Examination of the glands and tissues in these cases showed that all the diseased tissue had been unmistakably removed. In 23 cases in which he explored with his fingers, through the peritoneum, the glands of the region, he found them suspicious in 8 and removed them. In 4 of these the glands proved to be cancerous. In conclusion, the details of each of the 32 cases are given, and also a life-size photograph of the mass as removed from two patients.

62. Sarcoma of the Uterus.—Piquand discusses the symptomatology and diagnosis of sarcomata of the parenchyma, of the mucosa of the fundus and of the cervix. He has found 171 cases of the first group on record in which an operation was attempted. The operative mortality was 9.3 per cent. and recurrence is known in 29 cases. The ultimate outcome is not known in most of the others. In 36 patients with sarcoma of the mucosa seen a few months or years later, there had been recurrence in only 12 and 24 were in good health from one to eleven years after the operation. In 53 cases of sarcoma of the parenchyma, 28 of the patients were in good health from nine months to nine years after the operation. There are thus 52 permanent cures on record. In 19 cases of diffuse sarcoma of the mucosa, the uterus was removed in 16 and 3 of the patients are without recurrence from 17 to 26 months later, while 8 have not been followed and 4 soon succumbed. In 48 cases of sarcoma of the cervix, 3 patients died during the operation and recurrence was observed in 33. Only 12 are reported as cured, and the majority of these have not been traced since. The incomplete operations were always followed by recurrence.

63. Laparotomy as Treatment of Puerperal Infection.—Sourtille has treated 4 patients with severe diffuse puerperal peritonitis by mere laparotomy or posterior colpotomy, and succeeded in saving 3 of them. Removal of the uterus is a serious operation, and its record to date in puerperal infection is the reverse of encouraging. The outcome proves it to be either a useless mutilation or else that the prognosis was inevitably bad. A mere laparotomy or colpotomy enables the exact condition of the parts to be ascertained and has direct healing value in itself. As it entails no shock, he urges that it should be done early in case of severe infection, without waiting for the woman to be touched by the wing of death, after failure of curetting or drainage of the uterus. Done systematically, in time, it would enable the condition of the uterus and adnexa to be inspected, and, if a threatening lesion were found, to have it removed while the patient's resisting powers were still able to cope with a major operation. He reports a number of cases in which laparotomy or colpotomy unmistakably saved the patients in diffuse puerperal peritonitis or postabortion infection, and urges the general adoption of laparotomy with drainage as the routine procedure in threatening puerperal infection. Several surgeons have published reports of successful cases of this kind, but no one before, he remarks, has advocated this as the systematic technic for treating serious postpartum or postabortion infection. The entrance of air attenuates the virulence of the toxins and germs, especially the anaërobic, which, as a rule, are largely involved in puerperal infection. Dialysis is promoted and the drainage carries away the dialyzed morbid products.

73 Zur physikalischen Therapie der Neurasthenie. A. Laqueur.

65. Habitus Phthisicus and Tuberculous Dyspepsia.—Stiller has found that the floating tenth rib, which he long ago proclaimed to be a sign of the asthenic habitus, is also a sign of a consumptive tendency. This kind of body supplies a predisposition to tuberculosis as well as to nervous dyspepsia. The individual whose build stamps him as a candidate for tuberculosis is also a candidate for nervous dyspepsia. This explains why tuberculosis is complicated with dyspepsia in from 70 to 90 per cent. of all cases. He has found that the degree of movability and the extent of the defect in the tenth rib is an index of the extent of the dyspepsia and nervousness. In extreme degrees, the ninth rib may be movable also and the eleventh and twelfth ribs may move much more freely than common. He has observed a number of cases in which apparently healthy individuals sank into a condition of severe dyspepsia, neurasthenia and emaciation in consequence of some trivial stomach or intestinal trouble—in one instance a tapeworm. They lost rapidly from forty to sixty pounds or more, and years were required to regain their former weight. Signs of gastroptosis or nephroptosis developed in most of them. Some constitutional disease or latent cancer seemed probable, but the rib stigma showed that the individual was hereditarily burdened with a tendency to dyspepsia and nutritional disturbances. Circumstances had been so favorable hitherto that he had kept at the highest limit until some accident upset him. In such cases there must be not only a lack of stability in the digestive, but also in the assimilating organs, probably due to participation of the intestinal sympathetic system in the asthenia of the central nervous system. This serious tendency is revealed solely and alone, he claims, by the rib stigma in an otherwise robust physical development.

66. Roentgen Treatment and Leukemia.—Arneth's experience and study of leukemia under Roentgen treatment have convinced him that this treatment reduces the consumption of the neutrophiles, eosinophiles and mast cells of the circulating blood. The extent of the reduction depends on the duration and intensity of the exposures, which may lead finally to far-reaching, although never quite complete, restoration to normal of the blood. The morphologic behavior of the blood cells shows that there can be no question of destruction of the circulating leucocytes or injury of the blood-forming organs under the influence of the rays. Roentgen exposures have an entirely different action on the sound and on the leukemic human organisms, as he explains in detail. He defines leukemia as the expression of an immense destruction of leucocytes and consequent constant demand for production of more, with some special stimulus for the hyperplastic development of the blood-forming organs. This stimulus may be some special property of the still hypothetical virus affecting these organs.

68. Roentgen Treatment.—Cohn summarizes his conclusions in the statement that in lymphatic and myelogenic leukemia the exposures may induce subjective well-being, and all the appreciable objective signs of the disease may also subside, but experience has shown that the symptoms return, on complete suspension of the treatment, after a longer or shorter interval. It is necessary, therefore, after an apparent cure has been realized from prolonged Roentgen treatment, to continue intermittent treatment, with one or two sittings each week. Still better prospects are offered in Roentgen treatment of pseudoleukemia and of sarcoma originating in the lymphatic apparatus. Cancroids, when not too extensive, are positively cured in a comparatively brief time. In superficial cancers of the face, Roentgen treatment deserves the preference over surgical on account of the absence of scarring. Prophylactic exposures after a cure has been obtained should be unconditionally advised. More radical treatment than Roentgen exposures are required for carcinomata infiltrating into the deeper tissues or covered with sound skin. He explains the lack of influence of the rays on the enlarged spleen in many cases as due to the chronic hardening of the capsule. In exposing the spleen he uses excessively hard tubes, at a distance of from 10 to 20 cm., the sittings from ten to fifteen minutes long, once a day. To prevent dermatitis he orders the abdomen to be washed with a soft sponge and tepid water three times a day, and after each washing alcohol is rubbed into the skin to toughen it. At night, lanolin or other salve is rubbed into the abdomen. With these precautions he has never had any trouble from dermatitis, even when the total duration of the exposures was twelve hours without a pause. There is almost always slight transient redness of the skin after from eight to fourteen days, accompanied by itching, especially at night.

69. **Prophylaxis of Diphtheria.**—Aaser is convinced that preventive injections of serum are reliable for prophylaxis. He relates a number of instances in which incipient epidemics were aborted by preventive injections of antitoxin, even although exposed individuals were found to harbor diphtheria bacilli in their throats. As the immunity conferred does not last more than two or three weeks, he repeats the preventive injection after from two to four weeks if there is still opportunity for contagion.

70. **Hemochromogen Test for Blood.**—De Dominicis reaffirms the extreme simplicity and reliability of his test for detection of blood by means of the spectrum of hemochromogen. The loose scrap of dried blood is placed in a droplet of pyridin on an object glass and ground fine with a glass rod. A drop of ammonium sulphate is then added, and a cover glass placed over it. A chromatic reaction can then be observed, while hemochromogen crystals form, and the spectrum for hemochromogen becomes apparent. If the scrap of blood is on a dark background it must be made mechanically permeable to the light. A few mm. of a single thread of a blood-stained garment are sufficient to give the hemochromogen spectrum immediately and distinctly. This test gives positive results when others fail, and the spectrum is more sensitive than that of oxyhemoglobin. He commends this as by far the best general routine test for detection of blood with very little material.

75. **Behavior of Circulatory Apparatus in Acute Infectious Diseases.**—Schmaltz declares that the greater his experience and the more he is able to follow the consequences of infectious diseases into later life, the more he is convinced that every kind of infection is liable to injure the organs of the circulation, the injury ranging from the slightest, most transient effects to severe, fatal lesions. The injurious influence of the underfeeding and the long lack of exercise must also be taken into account. He reviews the findings and course of the cardiovascular affection in various acute infectious diseases. In 4 cases of diphtheria and 5 of scarlet fever, and in the majority of 52 other diphtheria and 19 scarlet-fever patients, the cardiovascular apparatus still showed disturbances when the patients were dismissed, and examination later confirmed the morbid findings. The trouble was generally mitral insufficiency, sometimes combined with subjective disturbances. He does not know of any research on the later course of the heart disturbances in cases of typhoid, measles and pneumonia. They frequently persist until the patients are dismissed, at least.

76. **Vascular Affections and Myocarditis in Children.**—In this first part of his monograph Förster discusses acute primary myocarditis, myocarditis after burns and in cutaneous affections and diphtheria. Fiedler described in 1897 an acute interstitial myocarditis as a primary and isolated affection of the myocardium. He had observed 5 cases of it and 4 have since been reported by others, all but one terminating in death. The patients were adults. Förster here describes the first case known in a child. Myocarditis after severe burns has been observed. It is liable to develop tardily in children. In 2 cases in his experience the children died on the twenty-eighth day after they apparently were well on the road to recovery. He has also witnessed a case of fatal myocarditis complicating eczema of the face and scalp. In diphtheria he notes that the frequency of myocarditic complications increases with the age of the patients, his figures ranging from 14.3 per cent. of the children under 2, to 88.8 per cent. of the children between 11 and 15. The insidiousness of the heart disturbances in diphtheria imposes the greatest caution on the physician, at least until after the fourth week, when he detects even the slightest intimation of a heart or vascular disturbance in the course of diphtheria. Repeated examination of the pulse, especially during the first two weeks, is indispensable in connection with examination of the heart. In his experience the first symptom was in the pulse in 10 and dilatation of the heart in 2—all in the first week. In the second week the pulse was the first symptom in 6, and dilatation in 6, with heart sounds in 5. He noted dilatation of the heart in 29 out of his 40 cases of diphtheritic myocarditis. In none of these patients to date is the heart absolutely normal again. When the myocarditis sets in early it generally proves more severe.

77. **Rheumatic Myocarditis.**—Geipel describes the findings in a number of hearts from cases of articular rheumatism. The findings are peculiar and pronounced, but they are not specific for rheumatism, as he has found the same in cases of contracted kidney, etc.

80. **Intraperitoneal Infusion and Feeding.**—Schmidt and Meyer report extensive research on animals to determine the tolerance of the peritoneum for injected solutions. Weak solutions of sugar and dextrin were promptly absorbed and did not cause material irritation. Oil was tolerated still better, and application of these findings in the clinic confirmed the fact that a small amount of oil injected into the peritoneum is tolerated without reaction and is absorbed. In 2 patients with advanced cancer the oil seemed to be absorbed and oxidized while the general condition improved. Intra-abdominal infusion of oil is far preferable to subcutaneous administration. It does not cause pain, and much larger quantities can be injected. The oil is rapidly absorbed and does not irritate the peritoneum in the least. When injected with a drug it seems to diminish the irritation from the latter. Infusion of solutions of albumin or sugar has not proved so practicable in several respects, at least in the concentration of 5 per cent. used in the tests reported. In regard to preliminary injections to enhance the resisting power of the peritoneum before an operation they describe their experiences with 5 to 10 c.c. of a 0.9 per cent. salt solution in from 250 to 500 c.c. of horse serum. In other cases the horse serum was used alone or the saline alone. The combination of the two, however, induced the highest leucocytosis. The infusion was made from seventeen to nineteen hours before the operation. The injection was almost entirely painless, and is a perfectly harmless procedure. It attains the desired aim, namely, the inducing of a slight irritation of the peritoneum with general leucocytosis. After experiments on animals several experiences were made with oxygen introduced into the peritoneum of patients with double pneumonia or tuberculous peritonitis or cirrhosis of the liver. The procedure proved feasible and harmless. The only danger might be that if the abdomen were very much inflated with the gas, some might find its way into the right ventricle. In the cases of tuberculous peritonitis the absorption of the

ascites seemed to have been promoted by the introduction of the oxygen. In one case in particular repeated tapping had been unable to arrest the formation of ascites, but after the introduction of the oxygen it did not reaccumulate and the patient was dismissed in comparative health. In this case, after withdrawal of 1,750 c.c. of fluid, 1,700 c.c. of oxygen had been introduced. In the course of the next week or so the abdomen increased somewhat in size, but not enough to require tapping, and before the month was out there was no further trace of free fluid in the abdominal cavity. The patient was a woman of 30. Further experiments with injection of sodium bicarbonate in diabetes and of cocain in severe gastric crises gave negative results, and signs of irritation deterred them from further experiments in this line. In any event, only weak and isotonic solutions should be injected. It is possible, they think, that fine results might be obtained by direct application of the drug when it is desired to exert a direct local influence on the peritoneum or intestines. In conclusion Schmidt and Meyer suggest the possibility of thus arresting hemorrhage with adrenalin, or of influencing tuberculous ascites by an emulsion of iodoform and glycerin, and also the practicability of reducing irritation by infusing oil or of influencing peristalsis by appropriate medication introduced into the abdominal cavity.

83. **Surgical Treatment of Splenic Leukemia.**—Lindner refers to a case in which the general health improved remarkably after removal of the spleen, although the entire syndrome of splenic leukemia was not banished by the operation. Four cases are on record in which the patients were restored to health by splenectomy, including Carsten's case. On the other hand, reports have been published of 28 cases in which no benefit was derived from the operation.

84. **Puerperal Embolic Lung Affections.**—Leopold relates a case in which a woman convalescing from childbirth had three severe embolic attacks with consecutive infarct in the lungs. The case is another example of the premonitory value of the climbing pulse (*Kletterpuls*), and it further shows to what grave danger the apparently healthiest parturient woman is constantly exposed for days. It also emphasizes the necessity for scrupulous avoidance of every unnecessary demand on the lung, heart and abdominal muscles. The probable source of the embolism was a varicose vein on the leg. The patient finally recovered.

87. **Appendicitis.**—Lucas-Championnière ascribes great importance to preceding influenza and to an undue proportion of meat in the diet as factors in the etiology of appendicitis. He operates as soon as the diagnosis is certain, unless from eight to ten days have already elapsed.

88. **Uterine Myoma.**—Knauer does not approve of electricity or caustics in treatment of myomata of the uterus. He advises expectant treatment when women are near the menopause unless forced by hemorrhage, pain or other symptoms of disturbance to adopt other methods. He operates through the vagina and warns against going too far in the effort to retain the uterus and thus compromising the later results.

90. **Dietetics for Children.**—Monti expatiates on the necessity for adapting the diet to the stage of development of the digestive organs and to the needs of the growing organism, giving detailed directions for children from 2 to 15 years old.

Address

CO-ORDINATED SPECIALISM IN PUBLIC HEALTH WORK.*

F. F. WESBROOK, M.D.

Director Minnesota State Board of Health Laboratories and Professor of Pathology and Bacteriology, University of Minnesota.

MINNEAPOLIS.

DIFFICULTIES.

In America two causes are operative in rendering it difficult to protect the health of the public. One is the lack of real knowledge on the part of the public in regard to the scientific truths which underlie the conservation of its chief asset, viz., its health; and the other is a tendency in the preservation of individual freedom to lose sight of our obligation to respect the rights and privileges of others who may be less assertive.

It is probable that each of these factors may operate as the cause of the other and it is difficult to discuss one without encountering complications dependent on the other. Endorsement of public health protective measures in a general way by an individual has usually the mental reservation that they be so applied as to safeguard him against his neighbor but not in such a manner as to impose hardship on him for his neighbor's benefit. The spread of accurate knowledge and the universal application of the golden rule are both to be advocated as necessary to secure permanency in the support by the public of the provision and enforcement of logical regulations which at present is only to be had under the stress of great fear, and is then but temporary and spasmodic. Individuals and families are willing to submit to nearly any course of treatment or to any restrictions imposed when the fear of sickness or death suddenly confronts them, but when the strain is removed they forget the lesson learned and the promises made. The public reacts in the same way and is willing to submit to discipline only when the necessity for it is plainly demonstrated by epidemics with high mortality or in the face of striking disaster. If such times could be utilized for the formulation and passage of logical regulations and the public could be induced to support the continuous administration of such measures and to take the same interest in the protection of its health as of its wealth or honor, progress would be rapid. It becomes necessary to convince the public, therefore, first, that health is its most important possession; secondly, that it can be conserved and improved just as accurately and certainly as any other asset; and, thirdly, that preventive medicine is immensely cheaper and more efficient than curative procedures.

In countries like those represented in our association where the right of the individual is the primary consideration, there is a particular prejudice against the assumption of special or expert knowledge on the part of individuals or groups of people, and yet it is necessary in the government of people by themselves that there should be specialization so that responsibility may be wisely placed and the greatest good to the greatest number insured. There is nothing, however, in which individual right to opinion is so rigorously asserted as in the matter of health; and through the medium of the press and in daily converse all kinds of peculiar and often pernicious views are voiced. The semi-mysterious seems to be attractive rather than the logical and those who are really interested in private welfare and public health are often tempted to long for a temporary monarchical form of government or military dictatorship if thereby the suppression of baneful theories of the cause, prevention and cure of disease and the advertisement of doubtful and dishonst remedies could be secured. This is, of course, impractical, but in lieu of it, the appointment of competent boards nominated by the leading national or international scientific, medical, public health and engineering societies so as to permit the preparation and censorship of technical material in popular form for distribution through the Associated Press and government bulletins, would result in the gradual education of the public. The substitution of real scientific truths, given in simple language so that children might readily understand, for the so-called "physiology and hygiene" now provided by some localities as text-books, would prepare our coming citizens to understand and protect themselves. Were such a comprehensive system feasible in the countries represented by our association, the question of the education of the public and of securing enthusiastic support for public health legislation and its administration would probably be solved.

DEGREE OF RESPONSIBILITY OF PHYSICIANS.

The total burden of responsibility should not be placed, as it frequently is, on physicians Their eager support of measures intended to safeguard humanity is usually misunderstood and misjudged because their honesty of purpose is questioned when they endorse methods which, if logically carried out, will diminish their financial resources. As a physician not engaged in active practice, I wish to pay tribute to the practicing members of the profession by asserting, without fear of successful contradiction, that they have no superiors in unselfish devotion to their fellowman, often in the face of a total lack of appreciation, and too frequently in the face of suspicion or active opposition.

The practicing members of the medical profession who stand highest in their particular lines are the most enthusiastic, honest and earnest supporters of public health protective measures, and urge most strongly the necessity of special qualifications and the broadest and most thorough training for those who are to be made responsible for their intelligent administration. They are the first to realize that their own training and experience, being largely in the direction of curing rather than preventing disease, must be supplemented by all the other allied sciences and that public health work has become a profession or a specialty which involves the necessity of a knowledge not to be obtained until in very recent years in the medical colleges, universities, engineering and technical schools.

---

* Presidential Address, American Public Health Association, Boston, Sept. 26, 1905.

A glance at the program for this meeting will give some idea of the complicated mechanism and careful training in varied lines which are required in the care of the health of the public; and their necessity should be recognized and demanded by the public. This most important matter should not be left, as it often is, in the hands of those whose knowledge and ability is along political rather than sanitary lines. Sanitarians have been far too little appreciated, not only by the general public but also by the medical profession. The general public is inclined to regard a public health office of any kind as a "political plum." Years of experience, each one of which adds to the knowledge and value of any official, are apt to count for naught. The medical profession, on the other hand, too often regards a physician who is willing to undertake work of a particularly arduous character which essentially differs from and precludes him from general practice and yields little financial return, as lacking in ambition, independence or foresight. Such posts have been, therefore, unattractive, since the remuneration is usually small and the loss of medical practice and prestige is likely to be as certain as the tenure of office is uncertain. Reform in this direction is growing. Universities are preparing to co-operate with boards of health in providing special training. The time is now ripe when the public should demand that those entrusted with the care of its health should have special training and higher remuneration.

It is absolutely necessary to place such work on a sure and firm foundation. The value of experience already gleaned should be recognized and every community should try to retain the services of officials who have shown their ability and faithfulness in the various branches of public health, as well as other public work. The city in which we meet has set an excellent example in this respect and is to be congratulated on her appreciation of the initial ability, integrity and wide experience of the chairman of her board of health, who for over thirty years has devoted his life to the welfare of Boston; has been a leader in our association almost since its organization, and was once its president. We of Minnesota have piratically annexed the director of the Boston City Board of Health laboratory and are still unrepentant, being selfish enough to want the best.

SPECIALISTS NEEDED.

The older method of securing experience by experimentation on the public should be superseded by requiring preliminary special training at universities and by boards of health, so that, while retaining for the good of the public the service of those already trained and competent, they may be reinforced and, when necessary, succeeded by those who have received such special training. Undoubtedly, the public should demand the possession of special qualifications both in the executive and in the other technical branches of public health service. Elective and appointive positions should be filled by those who have received special training and, as evidence of their special qualifications, have degrees or diplomas granted by competent authorities, as in Great Britain, where a diploma of public health is demanded of all medical health officers. Bacteriologists, chemists, engineers and other technical men should have special training in public health work before the responsibilities of public service are entrusted to them. A knowledge of the clinical manifestations of disease is imperative, but often much more than clinical experience and ability is essential. While in scarlet fever, smallpox and certain of the infectious diseases it is nearly always possible to diagnosticate the condition present and by so doing to protect others from infection, there are a number of diseases in which clinical observation alone proves utterly insufficient.

As illustrating this, diphtheria may be mentioned. It is the presence of diphtheria bacillus which constitutes the danger of infection. Preventive measures should be and are demanded when this bacillus is present. Bacteriologic methods have very greatly shortened the necessary isolation period. In diphtheria it is impossible to base the necessity for protective measures on the local condition of the throat or the general or constitutional manifestations of disease. For this work, and many other branches also, competent bacteriologic advice must be at hand. It is not the typical cases which cause serious trouble to the sanitarian, but rather those in which the diagnosis is unsuspected or obscure. In many conditions the laboratory is able to afford most valuable aid. A laboratory method of diagnosing smallpox has been evolved by Howard in the further pursuance of the classical researches of Councilman and his associates. The dread of cholera has to some extent disappeared by a better understanding of its cause and means of transmission. Here again bacteriologic methods are used almost entirely for diagnosis and the only preventive therapeutic interference which has been utilized is that of Haffkine, whereby cultures of bacteria are used for inoculation in order to induce immunity. The wonderful revolution in protective methods against yellow fever is well known to all. The work of Reed, who was vice-president of our association at the time of his death, can be credited already with the saving of thousands of lives, and the commercial benefits which have accrued to the American continent can scarcely be estimated since a prolonged period of quarantine and universal disinfection have been shown to be unnecessary and illogical. It is unfortunate that the wonderful efficiency and co-ordination of the methods employed by the United States Army in Cuba could not have been fully utilized in the present epidemic, but we Americans do not like discipline and as a result of a division of the responsibility and lack of far-reaching, supreme authority in the beginning, the ignorance and fear of the masses have lost our country many lives.

The startling results claimed for Japan in protecting her soldiers against disease in the field do not appear to be so much dependent on superiority in scientific methods as on a clock-like discipline and patient, far-sighted attention to detail. In the Japanese army the authorities seem to respect sanitary knowledge and to be willing and anxious to place responsibility on the sanitarians and medical officers, who are left supreme in their own domain. A similar policy, with careful selection and adequate recognition of the sanitary officials, would be found to be well worthy of emulation in Panama.

In malaria, practically the same measures are to be employed as in yellow fever, both of them involving the necessity for biologic knowledge, as it is very important to know and recognize the different members of the mosquito family. The activities of flies, bugs, vermin and other such agencies in the spread of disease have to be recognized and familiarity with general biologic principles is demanded on the part of the health official. The chemist must be utilized in the study of foods, water and sewage as they relate to the health of the public. Engineers now are specially trained in public health lines so that municipal and sanitary engineering are taught in certain of the technical schools and universities. The city in which we meet furnishes many communities with experts along such lines through the Massachusetts Institue of Technology. The Massachusetts State Board of Health by its scientific investigations in water supply, sewage disposal, food adulteration and kindred problems has won the respect of sanitarians throughout the world, not only by the methods evolved, but by results achieved. With the certain knowledge now available through our sanitary clinicians, statisticians, chemists, engineers, bacteriologists, biologists and other specialists, it would appear to be a relatively simple matter to conserve public health, but there are certain other factors which must be recognized and dealt with.

COMPLEX MODERN LIFE DEMANDS CO-ORDINATED PROTECTIVE EFFORT.

Apart from the difficulty of establishing satisfactory disciplinary measures in our free countries, it must be remembered that life in this age is extremely complex. Our cities have grown enormously. Facilities for rapid transit now make it possible for individuals to reside many miles from their work. Groups form and re-form many times a day, and it is impossible to know the exact previous environment of each individual who helps to constitute a particular group. Rapid transit means increased responsibilities for sanitarians. The grouping together of individuals in schools, colleges, religious institutions, offices and shops calls for a study of public health along social economic lines. Specialism in commercial and professional life is so great that we have diseases incident to occupation. It is very apparent that the difficulties of protecting the public against itself are increasing every day, and that both highly specialized and very broad general knowledge must be available in those who are united in this work. No one individual can acquire, so as to be able to utilize, all of the specialized knowledge in these various lines. It becomes necessary, therefore, to have all such branches available and co-ordinated. A short consideration of some features of necessary co-ordination may not be amiss. While we are often described as a practical people, impatient to utilize results rather than to acquire the original scientific data by tedious research, the description is true only in part. Anesthesia by ether, the determination of the causative factor in yellow fever and many other both scientifically and universally important discoveries have had their origin here. The brilliant work of Americans in the study, prevention and cure of tuberculosis is universally recognized, and Theobald Smith, Ravenel, Pearson, de Schweinitz, Biggs, Trudeau, Bowditch, Knopf, Flick and others are household names the world over. The ideal co-ordination of effort in the fight against this dread disease has been secured, and the National Association for the Study and Prevention of Tuberculosis will doubtless be the means of stimulating local effort in the utilization of every honorable means to educate and protect humanity. This kind of work shows the power and ability of our people, and it may be said that no countries excel those of America in the application of scientific methods to the protection of public health. The vastness of the countries and the possession of potential rather than actual wealth in the newer communities render the work more difficult, but as a compensation there is a corresponding freedom from the chains imposed by precedent and tradition. We are in the process of manufacturing these latter.

RELATION OF EXECUTIVE TO LABORATORY WORK.

Laboratories are utilized almost universally in America in public health work. There are, however, many misconceptions in regard to the function of the laboratory in public health service. Primarily, the work undertaken by such laboratories should be in direct relation to public service, and not a means of gratifying private curiosity or of affording information which is of value to individuals alone. Laboratory work should be extended wherever possible, so as to afford guidance to executive action. This does not at all mean a limitation to pure routine. Research is necessary, in fact demanded, along many lines. It should have for its object the study of conditions in order to obtain information which may serve as the immediate or future basis of executive protective activity and legal restriction. Universities, special institutions for research and private and hospital laboratories are available for the study of diagnostic and curative methods applicable to the individual rather than to the public, but it is in the public health laboratory that research along public health lines must be done.

In municipal health work, the laboratory is in close contact with the problems to be studied, but very frequently it is necessary for the laboratory men to leave the laboratory and to accompany executives, inspectors or others, so as to see and know the actual existing conditions and guide their work accordingly. In state or federal work, it is often imperative for the laboratory worker to visit the locality under investigation. It is impossible, in most instances, to render valuable service or to give intelligent advice based on shipped specimens and meager data. Nor is it economical to spend days, weeks or months in working at problems which have been entirely obscured or at best rendered vastly more difficult by lack of foresight or of specific knowledge on the part of those for whom the investigations are to be made. For years our experts have endeavored to show the impossibility of giving specific information in relation to the sanitary quality of waters or the location of contaminating foci, and to afford advice involving structural and other details by the examination of samples collected and shipped to the laboratory. The delay between collection and analysis has been an element of error, and even more so in sewage work.

Certainly in bacteriologic work it would seem strictly proper to begin the analysis of water and sewage in the field. In the examination of blood for *Plasmodium malariæ,* of sputum for *B. tuberculosis,* of blood for the presence or absence of the Widal reaction in typhoid fever, and of cultures taken from the throats and noses of suspected diphtheria cases and in a number of other lines including rabies, glanders, anthrax and actinomycosis, it is usually possible for the laboratory to examine and report on shipped specimens where intelligence has been exercised in their collection and transmission. At best, however, it is not ideal, because the value of data is frequently not appreciated by the person who desires the examination.

Furthermore, to be of value to public health administrative bodies, each piece of work should be capable of utilization as a guide to future work. Every individual who utilizes a public health laboratory for securing information should feel under obligation to make the necessary return for such gratuitous expert report, by supplying all data in regard to past and present conditions and subsequent history of events so that the whole may be recorded in such form as to be of permanent value to the particular locality and to sanitarians in general. No work on the laboratory or executive side should assume such routine form that it ceases to possess interest. The research spirit should so dominate the work that even in matters of so-called routine observations and records are made in such manner as to afford the possibility of arriving at new and conclusive views. Boards of health and officials in whom this research spirit is lacking are sources of danger to their communities.

When so much emphasis is laid on the use of scientific methods in medicine and public health there is danger that in the recognition of the value of such laboratory investigation and minute technical observation the absolute necessity for sound judgment and ability to appreciate relative values of the points brought out by such precise methods may be underestimated. It is too often assumed that in the various chemical, bacteriologic, biologic or mechanical tests the correct information and conclusions are rapidly and almost mysteriously attained. Many of the methods are most laborious and time-consuming. The microscope, the culture tube and the chemist's balance and retort are extremely delicate implements, which bring to light many new and sometimes complicating factors. Really, at times they almost seem to increase the difficulties and to lead away from practical results. Here is where the necessity for sound judgment, so erroneously designated "common sense," becomes most important, and where a knowledge of all local conditions must be considered and correlated with all other data. The only remedy for apparent discrepancy is more data and further study.

SCOPE OF PUBLIC HEALTH WORK AND METHODS.

In regard to the problems undertaken by sanitarians and laboratories, as a general principle the epicurean doctrine must prevail. Questions which involve the welfare of many should receive consideration before those which concern the interests of individuals. Problems for whose solution there seems to be a reasonable hope must take precedence of those in which there appears to be little likelihood of arriving at definite results.

Public health authorities established for and by the whole people should be independent of the coercion of individuals. Because a board of health is a public institution is no reason why any individual should demand investigation of the problems which interest him alone. Those who are actively engaged in public health service should be selected primarily on account of their fitness and because the people have confidence in them. To them should be entrusted not only the carrying out of the necessary work, but the formulation of that work. Sanitary laws and ordinances either should be formulated by health authorities or submitted to them for approval or modification and bodies whose duty it is to enact legislation should be guided by those who are entrusted with the protection of the public health. It is illogical to place individuals in positions of trust and responsibility and to hedge them in by suspicion or by perverse or inefficient legislative measures so that the successful carrying out of the work is impeded or prevented. Responsibility without adequate authority is farcical.

It is apparent, as we have seen, that nearly every phase of human knowledge must be utilized in successful effort to protect the health of the public. Usually on one individual the administration of the work falls. This being so, it is absolutely essential that he keep in touch with the other phases of the work, and at least be versed in their principles. The composite judgment of all the available experts should be secured and included in any final opinion which the executive voices and, so far as it can be done, expert work should serve as the basis of all executive action. Importance of close contact of laboratory workers with field problems can not be overestimated. The correctness of this conclusion has been proved by an experience of several years in the State Board of Health work in Minnesota. To facilitate such work, branches of the State Board of Health laboratory are being established throughout the state. In the saving of time, the accuracy of information received and the applicability of results of laboratory investigation to the work in hand, much is gained by such means. Where branch laboratories do not exist, one or more laboratory men accompany the executive officer or his representative into the field or at times the laboratory man is entrusted with executive power. A number of state institutions and hospital laboratories throughout the state are frequently used as temporary headquarters. It has been suggested, however, that for many phases of the work a traveling laboratory which can readily be provided in a railway coach would be most advantageous, as it would permit certain laboratory work to be finished much more quickly. In any event, it could be begun on the spot and completed in the main laboratory. In general, for problems including epidemics of the various bacterial or parasitic diseases, water, sewage, milk and food investigations and other matters, necessitating the presence of the laboratory worker in the field, such as a traveling railway laboratory, sidetracked for the purpose, would be most useful in the saving of time and effort and in serving as an object lesson. The expense would be very much less than that incurred by the provision of innumerable laboratories on a permanent basis in rural districts or small towns and villages. The chief benefit secured would be in the co-ordination of effort by the authorities and the instruction of the public in its own welfare. Such a plan was utilized most advantageously by Dr. Hamilton Wright in the Federated Malay States.

Railways find it most advantageous to provide themselves and the engineering departments of certain universities with laboratory cars containing instruments of precision and facilities for observation in their important problems, such as conservation of power, the adjustment of grades and the relation of speed to expense. Commercial enterprises and government and state departments have realized the utility of traveling laboratories in agricultural education whereby demonstrations can be given to farmers and others as to the most scientific and practical methods of increasing and conserving the crop yield.

AIM OF THE ASSOCIATION.

Each one of us has a different set of problems to solve, and it would be idle to attempt to go into all the various phases of work represented in our association. Our annual meetings permit each one of us to profit by the experience of others engaged in similar or parallel work. It has been the aim of the association from its very beginning to stimulate research and to standardize methods of technical and executive procedure. With the growth of the countries represented and the gradual organization of new territory our association has kept in touch. The increased tendency to utilize methods of science and accuracy in medicine and commerce has been shared in or perhaps led by the association in the establishment of its laboratory section. Considerable trepidation was experienced by many members for fear that in the division of the program interest might be divided. The real need which existed has been fully demonstrated by the history of the section which has shown the value to be obtained from the meeting together of technical men in the evolution and standardization of methods and interpretation of results. On the executive officer falls the necessity and responsibility of taking definite action, to suppress, eliminate or prevent conditions which are inimical to public health. The technical worker is apt to become interested rather in his methods or scientific results than in their practical application. The effect of the establishment of the section has been to interest each different worker in the problems and affairs of his colleagues in the same and other lines, and the blend has been beneficial. In this day of specialism it is necessary at all times to keep the inter-relation of the various phases of the work most clearly defined, and there is room for question as to whether the present arrangement of the program for our annual meetings is best suited to our needs. Undoubtedly we need one technical section and probably should have more. It may appear desirable perhaps to consider a greater subdivision into sections, such as executive, statistical, bacteriologic, chemical and engineering sections. Each section should include in its sectional business and program only those matters which involve technical points. The bacteriologist is interested in matters which pertain to the making of culture media, the preparation or technic of some particular stain and similar procedures, but every member of the association is interested to know the general principles which underlie these matters, and particularly interested in the results to be obtained by their application. A chemist is not necessarily interested in structural materials or the methods employed in estimating engineering problems, but chemists and all other members of the association are interested in the results achieved by engineers and the general plans and principles of the work which they undertake. The minutiæ of chemical technic are profitable only to the chemist. Executive details and legislative matters are of chief interest to those who are entrusted with the administration of such affairs in their own communities and the other technical workers are interested only in a general way, or insofar as these matters affect or complicate their work. It would be necessary, however, to scrutinize program material very carefully in order to determine whether it is of sufficiently technical character to be of interest only to a particular group of technical men, or if it is of general interest. If it is not particularly technical and deals with matters of general interest and importance, it should certainly be considered in general session. Most of the work undoubtedly should be done in joint session so that all members may participate and the meetings may continue to be the means of harmonizing rather than separating the various active factors in public health work. The ideal arrangement would consist in the grouping of allied subjects. To illustrate: A joint session on the subject of typhoid fever would be valuable. The bacteriologists might present papers dealing with such general matters as methods of isolating *B. typhosus* from various sources and the germicidal effects for typhoid bacillus of certain substances with which they may have experimented; or of their experience as to the value of the so-called Widal reaction; or of the persistence and localization of *B. typhosus* in the human body. All of those matters should be presented in the most practical way without emphasis on minute technical details. Both chemists and bacteriologists might be able to afford data concerning food, milk and such other materials in relation to the spread of typhoid fever. Engineers should participate in such a program, giving the results of their inspection and investigation of water supplies and sewage disposal. Executive officers and statisticians should give their experiences, including the use of legislative machinery, the administration of regulations and the compilation of statistics. The relation of the disease to railway travel and military life should not be overlooked. Such a method of approaching problems would enable each worker to arrive at, modify or change the point of view of his fellows, and a far greater value would be received by all than if all of each technical worker's experience and results were to be given before his particular section simply because his communication contained technicalities. These technicalities should be eliminated from the general paper and presented in the briefest possible way and usually in a demonstration form before the particular technical section to which they belong.

The American Public Health Association is the only association of any magnitude which is devoted entirely to the interests of public health. Its traditions are that it should be big enough and strong enough to meet emergencies and keep pace with or rather to anticipate advance. Every one in this age and generation is familiar with the trust method as applied to commerce. Its opponents are loud in their denunciation of the method—not because it does not succeed, but because it succeeds too well. The success of the trusts is due to the fact that every method and every agency which can be advantageously used is used. There is a complete correlation of all potent factors. Such should be the attitude of our association, and success will attend our efforts if made along these lines for the benefit of the people whom we serve.

ORGANIZATION AND PROSPECTS OF THE ASSOCIATION.

The work of the American Medical Association in the organizing of physicians throughout the United States is one of the greatest advances of the present time. This work is very largely entrusted to one of the oldest and most valued members of our association, and it is impossible to estimate the real good which is being accomplished by Dr. McCormack in persuading members of the medical fraternity to drop all points of difference and unite on those matters which are common to all and for the good of all humanity. This work of organization does not contemplate for a moment interference with other more highly specialized or technical medical associations. It will be of the greatest possible benefit to our association, which has a field peculiarly its own. It should be the policy, however of the American Public Health Association to anticipate demands for special work and special information along lines which are closely applicable to public health, and care must be taken that in our land of societies without number we do not lose because we have failed to provide a place and a stimulus for workers in all lines which directly affect our work.

There are great difficulties to be met and overcome. Not least is the instability of local organizations, and our association should at all times endorse the great value of experience and the importance of continuing competent workers in their positions. Effort should be made not only to enlist the active co-operation of every good public health worker in America, but to retain him in active membership in our association. It is axiomatic that what is difficult to obtain is appreciated. On this principle it may be wise to consider the desirability of a more careful selection and rigid censorship of the membership of our association. Another point worthy of consideration is the effect on our meetings of selecting some central location as a permanent meeting place, provided that the educational effect both on the association and the locality visited be not lost. Succeeding meetings now may be held many hundreds or thousands of miles apart, rendering it at times very difficult for members to attend. The time of meeting also should be considered in relation to universities because of the necessity which all recognize of securing the co-operation of educational institutions in the general teaching of hygiene to all, and in the specific training which is essential for those who are afterward to engage in public health service.

The dignity and permanency of the American Public Health Association may be taken for granted, and it must continue to feel its responsibilities so that it may become advisory to the governments of those countries which constitute the association. But the question arises as to whether its present constitution which provides for an annual meeting lasting five days, with a complete interregnum of 360 days in each year, is best calculated to meet emergencies and bear responsibilities, and whether it tends to permanency of structure and administration. There are many matters which arise between meetings which demand careful consideration and immediate action.

The publication of the transactions of the association is a matter which has engaged our attention for years and is still unsettled, partly through lack of funds and partly on account of our peculiarity of organization. The question of income so that research may be fostered and possibly studentships or fellowships established for the study of specific problems, is an important matter which we should consider. I would suggest that at this meeting the association take under advisement some of the matters touched on and that the possibility of certain changes in organization be considered. To secure greater permanency of administration and for the purpose of carrying on at all times the necessary business and of increasing available funds, it might be well perhaps to consider the establishment of a board of trustees similar to that of the American Medical Association. The administration of the affairs of the association could be safely left to such a board, which should represent every phase of public health activity, and whose members should be long enough in office to ensure the carrying out of permanent policies.

Public health work in the main consists in making people do what they do not wish to do for their own good, and is certainly not a popular profession. As one of the younger members I can not but speak with enthusiasm of the work and achievements of the older members of our association, which, through their efforts, has been such an active factor in public health work for over three decades. Their motto has been to retain what is good, but to be on the watch for something better. It must be remembered that this is a work in which many of our members have been engaged for the greater part of their lives with relatively little financial encouragement and at times no appreciation of what they are doing by those for whom they are doing it. Their reward should be the contemplation of and participation in the working of a huge machine of which the constituent parts, revolving though they may be in intricate and complicated cycles, yet with no loss of energy in friction, operate for the benefit and conservation of mankind.

THE TABETIC FOOT AS A FACTOR IN THE ATAXIA OF THE LOWER EXTREMITIES IN TABES DORSALIS.*

SIDNEY I. SCHWAB, M.D.
Professor of Nervous and Mental Diseases Medical Department of St. Louis University.
AND
NATHANIEL ALLISON, M.D.
Instructor in Orthopedics Medical Department of Washington University.
ST. LOUIS.

This paper, the joint production of a neurologist and an orthopedist, attempts to bring facts toward a solution of a problem hitherto considered strictly neurologic in character, with the purpose of supplying in each case knowledge which is lacking in the other. The advantages of such a combination are obvious, and in the case of this paper, as in other instances, the different points of view have tended to solve a problem which up to this time has not been considered in all of its different phases.

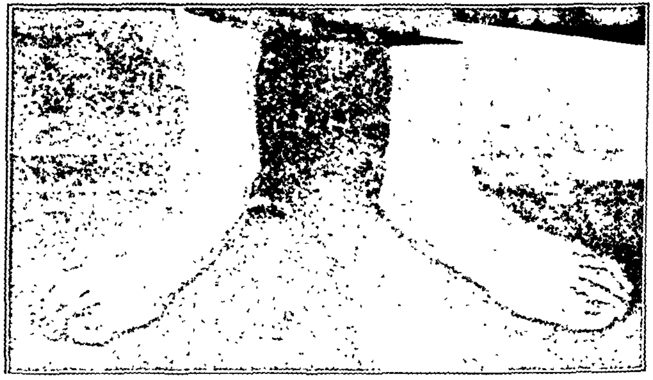

Fig. 1.—Pronation to a high degree. See Tracing I, Fig. 2, showing preservation of the arch.

THE PROBLEM.

The problem set before us was, in brief, the consideration of the factors concerned in the ataxia of the lower extremities in tabes dorsalis, apart from the usual elements which have been considered the essential ones. The theories of tabetic ataxia have been considered chiefly with the view of those who believed that the ataxia was a result of disturbances in sensibility, using the term in its broadest sense, or of those who held that the origin of the ataxia was central. Our own efforts were not concerned with this side of the question at all, but strictly with the tabetic gait and factors in the causation of this gait, apart from the disturbances in the sensory nervous system. In the walking and in the standing of the tabetic there are easily two sets of factors involved, one has to do with disturbances leading to the ataxia and the other with the instruments by which the peculiar gait is accomplished, that is, the mechanical factors involved in walking and standing. This paper, then, is concerned chiefly with the mechanics of the tabetic gait as influenced or not by the mechanics of the foot, ankle and, to a lesser extent, by those of the knee joint.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

As a consequence of the observations afterward to be recorded, an effort was made to correct the obvious errors in the mechanics of the foot and ankle used in walking by devising an improved shoe. This has developed gradually as the correct mechanical principles involved in a tabetic gait became more and more impressed on us. Thus the paper may be considered from two points of view, first, a study of the mechanics of the foot and ankle in tabetic gaits and postures, and, second, an attempt to improve the faulty mechanism so that a tabetic will be given a fairly normal implement with which to learn to walk. It might be noted here that from the therapeutic point of view the limits of this paper must be obvious, for the reason that results in therapy depend for their proof on a large number of observations made by a large number of different individuals.

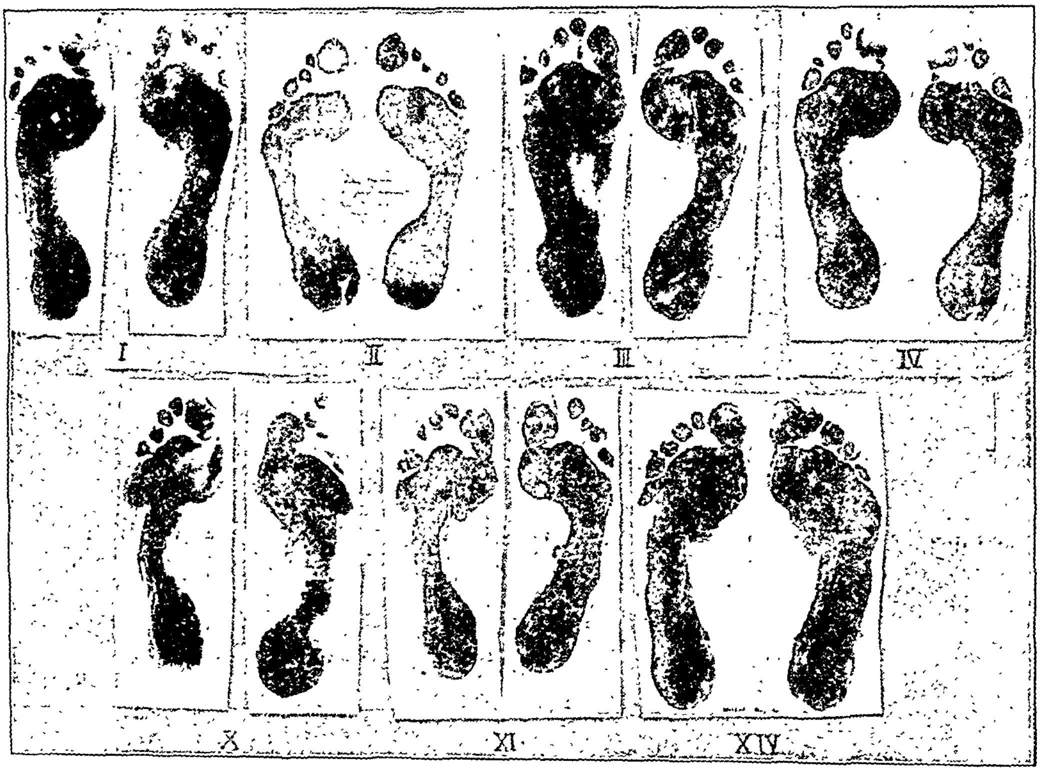

Fig. 2. Tracings of tabetic feet showing preservation of longitudinal arch and pronation as shown by the outer edge of foot raised from paper, X and XI especially.

MATERIAL.

The material on which this paper is based consists of fifteen cases of tabes dorsalis observed during a period of two years. The number was thought large enough, as no question of statistics was involved and no source of error due to small numbers of observation was an important element. Furthermore, this small series could be easily controlled and observed. In no sense was the material selected. As time and opportunity presented, these cases were examined, the results noted, and the final conclusions were determined from the facts observed in the whole material. The methods of study were very simple. The cases were studied clinically by the usual neurologic examinations. The diagnosis in none of the cases is open to the slightest doubt. The gait and posture were studied by both of us at many different times, and the conclusions so determined were carefully discussed in the light of the data obtained by measurements, photographs, tracings and foot prints. With the general principles so determined, the attempt at therapy was based and the improvement in gait noted.

LITERATURE.

Scant mention of the tabetic foot in the sense used in this paper is to be found in the literature of tabes or in the orthopedic literature which treats of the pronated foot.[1] A brief note on the hypotonic flattening of the foot in dementia paralytica is given by Féré.[2] There is one tracing of such a foot included in his paper, but no mention of the pronation and none of the arch. Féré thinks that the flattening is due to the hypotonia plus the increasing weight of the patient which he studied. There is no hint contained in the paper that he finds any connection between this and the ataxic gait. The foot shown, however, is very like the ones which we have studied in our work. Most of the literature on the so-called tabetic foot—*pied tabetique*—is concerned with descriptions of the arthropathies in the feet of tabetics.

[2] Féré: "Note sur L'Applatisement Hypotonique du Pied chez les Paralytiques Generaux," Nouvelle Iconographie de la Salpetrière, No. 1, 1904.

In Hoffa's[3] well-known monograph there is no mention made at all of the points brought out in this paper, although he has a material of twenty-six cases of tabes in which various orthopedic measures were tried.

There is frequent mention made of club foot in tabes called *pied bot tabetique* by the French writers, who seem to have done most of the work in this connection. Joffroy, in 1885, described this deformity for the first time. He seems to have realized that it differed from the ordinary club foot. He lays particular stress on the fact that the club foot of tabes is not due to the atrophy of the muscles as in the paralytic club foot, nor is it due to an osseus process, but to the flaccidity of the muscles. He calls it the atonic club foot. The hypotonia plays here also an important rôle.

Idelsohn,[4] in a paper on the pathology and histology of the tabetic foot, considering this term only as descriptive of the tabetic arthropathy, mentions the frequency of the combination of the tabetic foot with flat foot. This, by the way, seems to be a very commonly accepted opinion, the frequency of flat foot in tabes. It is to be regarded as an error in observation, because the tabetic foot is not a flat foot at all, but is a pronated foot. To the orthopedist this distinction is obvious enough. These brief and altogether unsatisfactory references are all that can be found in recent literature. It seems to show that the points brought out in this paper have not been given the proper degree of attention or that the very patent fact of foot deformity in tabes has been regarded as definitely settled when the term flat foot has been used to describe it.

As to our own observations on the gait and postures assumed by tabetics, we have noted a marked variation in degree and kind, depending apparently on the amount of ataxia, with the reservation that complicating factors, such as blindness, double vision, etc., are excluded. On standing, the tabetic unconsciously assumes a position which supplies to him a broad base of support. This broad base is secured by strongly everting the feet and standing with the knees well apart and at times one foot or the other advanced. The gait, which has been described as pseudo-spastic, is simply a progression of this standing position. The strongly everted foot is lifted and brought forward with an uncertain sort of slap and placed on the ground in a position of eversion. Oppenheim,[5] failing to note the importance of the eversion and pronation of the foot, thus describes the typical gait in tabes: "The patient lifts the free leg abnormally high by means of the overacted flexion and outward rotation of the hip joint. Then he throws it down forcibly, meanwhile overextending the ankle joint and foot, so that the foot is set down in a stamping manner, heel first. The knee of the resting leg is abnormally strongly overextended. He walks rapidly with unequal steps, looks always with his eyes fixed to the ground and would fall if he turns his eyes in another direction." The toe falls to the ground, because the heel strikes first. The gait may be described in a few words as pseudospastic, uncertain, irregular and everted.

As Whitman[6] has shown, there is a marked mechanical disadvantage produced in either standing or walking with the foot in an everted position, as the body weight falls inside the tarsal arch and the tendency is to roll the foot inward. i. e., pronation. Accompanying this pronation of the foot the weight-bearing line also falls to the inside of the knee joint. These two mechanical disadvantages we have observed to be very evident in our series of cases. The degree of pronation was so striking in many of these cases, as, for instance, in Case 1, that the feet presented the appearance of being absolutely flat.

Tracings were taken in order to demonstrate the presence or absence of the arch of the foot. Invariably it was found that the arch had not collapsed. In some of the tracings the outer edge of the foot is raised from the paper, showing the degree of pronation present. In none of the tracings is there any evidence of arch obliteration. The discrepancy which exists between the appearance of these feet in standing and walking and the evidence as shown by the tracings is perfectly apparent. The feet were found to be flexible to a marked degree. This flexibility in many of the cases extended to a condition of hypotonia.

As far as these fifteen cases go, we are inclined to the opinion that the tabetic foot is a pronated foot; that this pronation is a result of the tabetic changes in the cord and peripheral nerves which make it necessary on account of the loss of muscle sense and other sensory changes for the individual so affected to assume the everted pseudospastic gait; that the arch of the foot is not collapsed, but that it is much lowered, due to the hypotonic condition of the muscles; that this pronation as well as the hypotonia, varies from the extreme condition, which the photograph (Fig. 1) shows, to a condition where the pronation is not easily observed, and that this variation seems to depend on, or rather to accompany, the amount of ataxia.

In observing these cases it immediately occurred to us that a correction of this faulty walking machine would be of benefit to the patient. The things to be accomplished seemed to be to correct the pronation and to hold the foot when bearing weight in a supine position, to construct a shoe that would supply a broad standing base. These needs being fulfilled, it would be possible for the tabetic to learn to walk much more readily and comfortably than when handicapped by the mechanical disadvantages incident to eversion and pronation.

It might be mentioned in this place that the Fraenkel[7] method of exercise treatment was used in most of these cases in conjunction with the attempt to improve the mechanism of walking.

We at first placed under the feet of our patients the ordinary steel flat-foot plates designed to correct pronation. It soon became apparent, however, that it was necessary to supplement this form of support by broadening the walking base. Later we have given up the steel plate and are depending on a modification of the shoe designed by Mr. Thomas[8] for the treatment of ordinary valgus. Briefly, this shoe presents the following points: The heel is run forward on the inside to the distance of from half an inch to an inch. Between the inner and outer soles a wedge-shaped piece of leather is placed which is designed to raise the foot at its inner edge an eighth to a quarter of an inch. Various flat-foot appliances, such as cork pads or steel plates, are placed in this shoe to support the hypotonic arch. Some of the patients presented a hypotonic condition of the ankle joint, which we have treated by having a leather stiffening in the inside of the upper.

As a direct result of the pronation there is undue strain thrown on the knee, transmitted to the hip and affecting the spine. Dane,[9] in an article entitled "The Effect on the Leg of Pronation of the Foot," comes to the following conclusions: "In addition to the generally recognized motion of the malleoli inward and slightly downward, the normal outward rotation of the tibia is replaced by an exaggerated rotation inward. These changes acting together produce an alteration in the obliquity of the axis of flexion of the ankle joint sufficient to destroy the mechanism by which the normal joint is enabled to support the body weight. As a consequence, flexion must be prevented and equilibrium be maintained wholly by muscular force. This increased rotation of the tibia interferes to a great extent with the operation of the mechanism by which complete extension of the knee should lock the joint and render it proof against the constant tendency of the body weight to flex it. The knee must, therefore, in subjects with pronated feet be kept in extension by constant exercise of muscular force."

From a clinical point of view, the cases offer nothing of interest. They represent an average lot of tabetic cases such as come to every neurologist. Excluded from this series are bed-ridden tabetics, and those who have arthropathies of the feet, and those who have any complications which in themselves might explain the condition of the feet.

From the tracings here shown the character of the feet is apparent. That they are pronated can not be denied, and that they are not flat feet is also definitely proved. An interesting point might be mentioned here, and that is that there is very evidently some relation (how close we are not yet ready to say) between the degree of pronation and the degree of ataxia. This is well shown by Fig. 2. This is the most normal foot in the series and this case had absolutely no demonstrable ataxia. We are inclined to believe that this observation, if it is proved to be a fact, will be of some diagnostic and prognostic importance.

THERAPEUTIC ATTEMPTS.

In the face of the obviously wrong mechanics of the tabetic's implement of walking, a correction was indicated, based on the degree and the kind of deformity found. This correction was only gradually arrived at, as we were on absolutely new territory. The shoe that we are using now is the result of a number of experiments, and we are by no means as yet certain that we have devised the perfect shoe for the ataxia gait of tabetics. The following represents the principles on which the shoe was devised and the reasons for each improvement:

The internal excursion of the ankle and the inward rolling of the foot we have tried to overcome by means of an artificial support, realizing that, in addition to the mechanical disadvantages in walking, the position tended toward abduction and flattening of the long arch of the foot. The plate known as the Whitman plate is in the ordinary case an effective devise for the correction of pronation, reminding the wearer at each step by its pressure on the scaphoid that the foot must be supinated. The nervous changes in tabes dorsalis leading to anesthesia remove this element and make it necessary to have a support that gives definite pressure to counteract the pronating tendency. After we had tried various steel supports, we came to the conclusion that the difficulty was not in holding up the arch, but in preventing the inward roll of the foot. This fact has been demonstrated by Hoke and Bradford.[10] We found it to apply especially to the tabetic foot, having the above nervous elements to combat.

The shoe designed by Thomas we have used of late with the best results. This shoe shifts the weight to the outer side of the foot and holds the foot in a supine position. Using the knowledge given us by Hoke and Bradford,[10] the support inside this shoe is placed so as to supply the lifting resistance beneath the internal cuneiform bone, that is well forward of the astralalus in order to check the pronation. A cork insole cut so as to meet these conditions we have found by experience to serve better than a steel plate, its points of advantage being its lightness and the lack of dangerous rigid pressure.

Realizing that the tabetic needs a broad, sure footing, we have used an ordinary broad, straight-last, laced shoe. To this we have added the lengthened heel and the raised inner edge as the main factors of correction. As to the amount of supination necessary we have had some difficulty; at first we put all of our cases into well-marked supination, throwing the weight well to the outer arch of the foot. In some of the cases it soon became apparent that this position was causing trouble, as there was too much strain on the ligaments. As a result of this development, we have been trying of late to judge the amount of pronation in a given case and to give to this case a support that corrects this pronation, but does not overcorrect it.

Another point that is of less importance, but that nevertheless has aided some of our patients to a material degree: we found that by putting a series of transverse cleats on the sole of the shoe the footing was made more secure; these cleats are similar to those that are seen on the shoe of a football player. They are one-eighth of an inch high and run across the sole zigzag or straight lines about an inch apart, three in number. These cleats have given an added sense of security, especially when the patient is walking on a plane surface; incidentally the increased height has prevented, in one case, the toe striking the ground in the forward movement in walking. In several cases the hypotonia has been present to such an extent that the ankle joint has needed support; this need has been filled by adding a leather stiffening to the inside of the upper of the shoe. Such a shoe as this we have found to be of undeniable advantage to this class of cases. It is important to have the sole and heel level so that the surface contact is perfectly applied, allowing no rocking.

In regard to the therapeutic results of this study, we are much inclined to be very conservative, as is consistent with a method as new as this one is. We have little doubt, however, that the patients to whom we have given the shoe have shown from that time on a marked improvement in their gait. They all have said that they feel very much more comfortable, have less hesitation in walking, have more confidence in themselves and are enabled to walk greater distances than before without fatigue. From our own observations we are convinced that the improvement in these patients is not imaginary, suggestive or due to faulty observation. The striking improvement in the posture of these patients is well worthy of note and is particularly of value because some of them had occupations that required upright positions for long periods of time. From a mechanical point of view the tendency to assume normal attitudes in both walking and standing was especially striking. Another factor of some importance was the disappearance of pain in some of these cases. If the pronated foot in otherwise normal individuals causes pain by the overexertion of certain muscles, this same condition must be harmful in tabetics. We feel that further study in this direction may throw some light on the production of the arthropathies in tabes, for the reason that faulty attitudes, by throwing weight and strain on structures not designed to withstand them, may more easily become the seat of the joint and bone changes typical of those found in tabes dorsalis.

CONCLUSIONS.

1. This series of observations has shown unquestionably that the foot of a tabetic with any degree of ataxia in the lower extremities is a pronated foot.

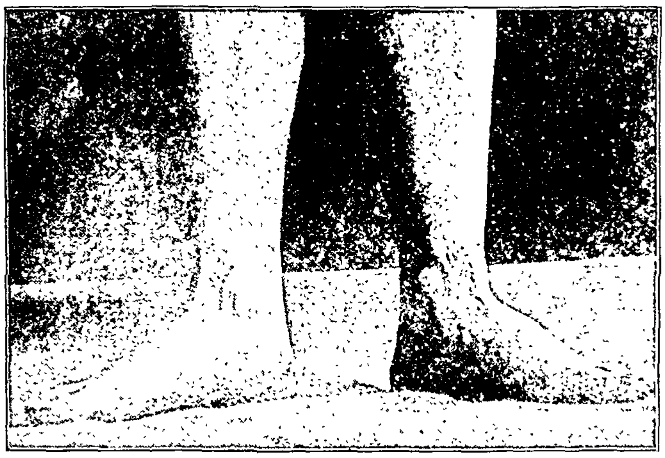

Fig. 3.—Standing position of a tabetic showing strongly everted feet.

2. The effect of this pronation leads to muscular strain on the ankle, knee, hip and spine. This, together with the hypotonia, tends to break down the long arch, thus producing a faulty mechanical instrument by which walking is accomplished.

3. The pronated foot plays an important and hitherto unrecognized rôle in the production of the ataxic gait in tabes.

4. Correction of this faulty mechanism tends to increase the ability of a tabetic to learn to walk normally.

5. In conjunction with the Fraenkel method of exercise treatment, the correction of the faulty mechanism of the foot indicated in this paper offers the most favorable treatment for the ataxic gait of tabes dorsalis.

DISCUSSION.

Dr. H. T. Pershing, Denver, Col., said that in the past efforts to relieve tabetic symptoms have been very restricted, and that anything which will enable the patient to walk better is likely to be of very great service. Dr. Pershing mentioned the shoemaker, told of by Dr. Patrick several years ago, who made a special kind of shoes for tabetic patients and sold them for $100 a pair. Dr. Pershing said that at first it seemed absurd that any one would be willing to pay such a price for a pair of shoes, but now he can easily see that a pair of shoes properly made to correct the mechanical defects in tabes would be worth a great deal more than that. He classes the orthopedist nearer the neurologist than any other specialist, and stated that he gets more help in his work from his colleague, Dr. Packard, an orthopedist, than from any other man. Dr. Pershing also mentioned the fact that Dr. S. Weir Mitchell's Hospital in Philadelphia is known as the Orthopedic Hospital and Infirmary for Nervous Diseases.

Dr. John Punton, Kansas City, Mo., said that all neurologists who treat tabetic patients know how limited are the means for giving them relief, and that any method of treatment which assists in any way to overcome the ataxic gait is most valuable. If the method advocated by Dr. Schwab can be borne out by practical experience, Dr. Punton considers that he has made a step in advance in the treatment of tabes, for which he deserves thanks.

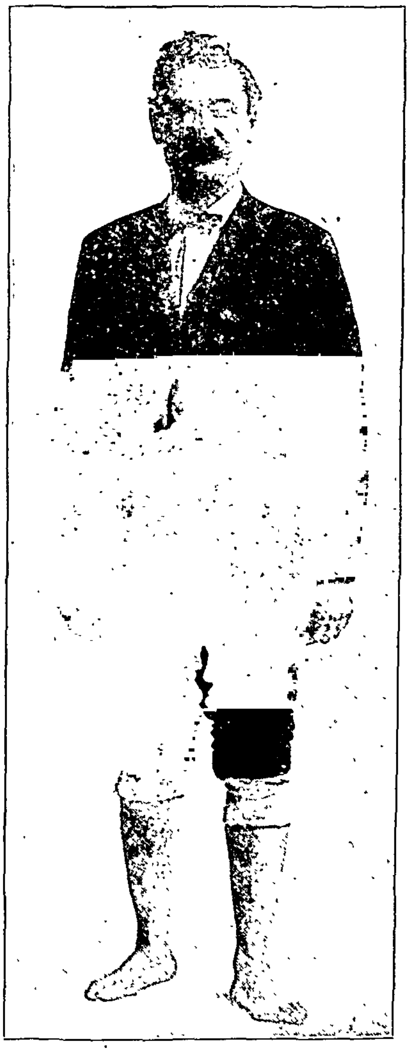

Fig. 4.—Everted pronated feet in tabetic gait.

Dr. Smith Ely Jelliffe, New York, declared that when an individual has an ailment that is bound to last for 13, 15, 20 or 25 years most physicians lose enthusiasm in his treatment. The physician is apt to tell such persons that there is very little to be done for them, and as a consequence they stray into the hands of irregular practitioners and help to make those individuals successful. Neurologists are to blame, Dr. Jelliffe said, for not taking enough pains with these patients. In referring to shoes for tabetic patients, he said that, while shoemakers in Chicago charge $100 for a pair of shoes for these patients, in New York one man charges from $3,000 to $4,000. A shoemaker there has profited for many years in the construction of special shoes for tabetic patients for which he charges a special price, and the chief reason that he is able to succeed is that very few neurologists and very few orthopedists have taken as much pains as that shoemaker has. He is entitled to his profits, to a certain extent. Neurologists are not quite so careful nor so optimistic as they might be, and the cases drag on indefinitely because of the obvious past experiences in the treatment of tabes.

Dr. David I. Wolfstein, Cincinnati, Ohio, said that he knows of a man who paid $750 for a pair of these shoes, and he had to take them back to the shoemaker to have them fitted. The man returned home very happy with the shoes, but in about two or three months he ceased wearing them and the shoemaker had the $750. Dr. Wolfstein does not know what became of the shoes. He asked Dr. Schwab whether or not progression in the hypertonicity would be overcome by correction applied to the tabetic foot, and if he has had an opportunity to examine the condition of the tabetic hand in cases of ataxia of the upper extremities, and whether or not that is explained by the same conditions as in the foot.

Dr. J. W. Putnam, Buffalo, N. Y., said that it is the original name of the disease, progressive locomotor ataxia, which has so influenced physicians and made them unwilling to attempt the treatment of the disease. One must be careful to avoid too great confidence in any system of mechanical correction, for no mechanical correction can be of permanent value. When suspension was first used in the treatment of locomotor ataxia the explanation was made that it relieved the patients by stretching the spinal cord and changed the nutrition of the cord, and that the benefit to the patient was permanent; but as years went by and the number of observations continued the number of patients that were benefited decreased. Dr. Putnam believes that the greatest advance made in the treatment of locomotor ataxia was started by Fraenkel in his movement treatment. He gave the patient at first the simple movements and when he was able to accomplish these he added more difficult movements, such as walking backward, and lengthened the steps. It is simply in the development of the muscles along that line that the education comes to the legs, just as the education comes to the hand of the skilled piano player. The more one gives exercises and the more these are varied the more the direction of the nerve paths is changed; the more self-reliant the patient is made the more he will improve. When he becomes more able to carry out the difficult movements the simple movements become easier. The same thing is true in regard to the mechanical correction. It is the importance of the relative position of the shoes, of the relative balance of the muscles. The two factors must work together. If the patient relies on a $5,000 pair of shoes, minus the *Fraenkel* movements, there would not be much benefit. This correction of the tabetic foot is of very little value of itself, but in combination with the education of the brain and the development of the muscles many of these patients may obtain a great deal of benefit.

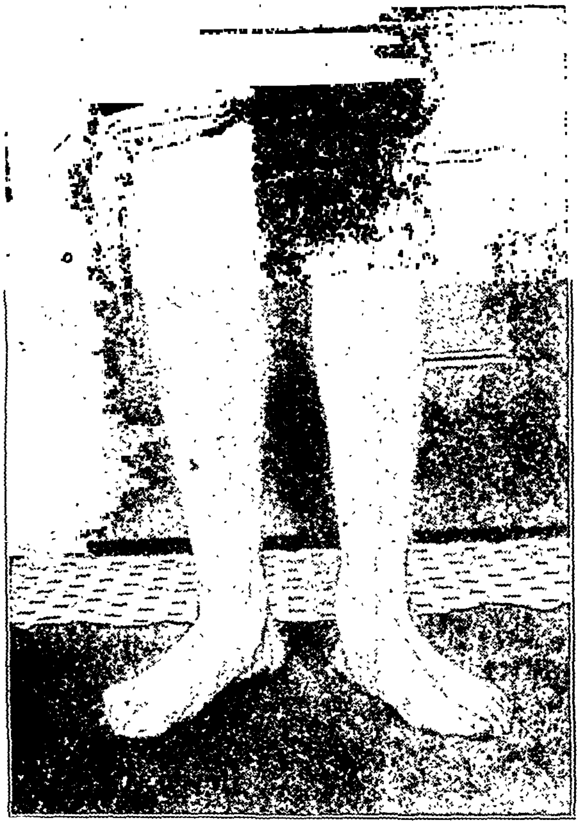

Fig. 5.—Pronation and eversion of feet in standing.

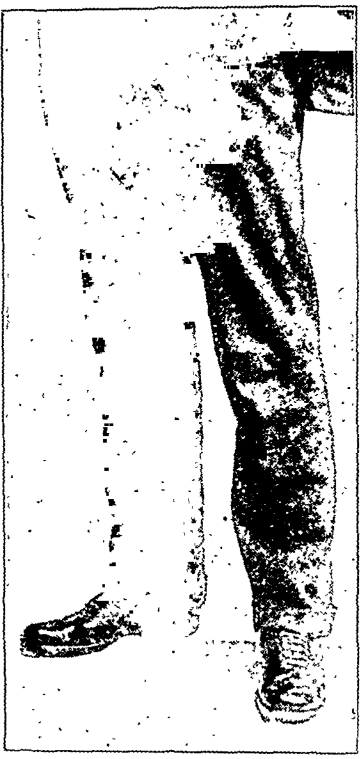

Fig. 6.—Corrected attitude of tabetic wearing modified shoes.

Dr. Sidney I. Schwab stated that an investigation based on fifteen cases must be regarded as preliminary to further work along the same lines. There is a possibility that further study in the mechanics of the tabetic foot will give much valuable information. When he spoke about the two or three patients who never had any pain after the shoes were worn, he did not refer to the typical tabetic pain, but to muscular pains which were attributed to the wrong position of the foot. He emphasized one point in regard to combining this method with that of Fraenkel and that has reference to the effect on the patient in a psychologic sense. The greatest relief that one can afford tabetic patients with ataxia of the lower extremities consists in the restoration of their gait to somewhere near normal conditions. Most patients do not care whether they have a knee jerk or not. They do not care whether they have an Argyll Robertson pupil or not, but they do care about their inability to work without exciting attention. The thing that separates a tabetic from the rest of the normal world, from his point of view, is his peculiar gait. If that can be corrected so that it approaches to the normal, then many thousands of happy moments are added to the tabetic's life. The patient's chief concern is centered on this point. If the gait in a tabetic can be corrected, all that can reasonably be expected from therapeutics is accomplished. The shoe as Drs. Schwab and Allison have planned it adds about three or four dollars to the cost of a good shoe. They have heard that a very expensive shoe for tabetics which is manufactured at an excessive price is on the market. The probability is that this shoe is made with a very broad base, thus insuring a certain amount of firmness to the patient. In respect to the effect of this treatment on the hypotonicity, Dr. Schwab does not feel that the material is sufficiently large to speak with any certainty. He has no means of observing the degree of hypotonicity or rather of measuring its extent. Certainly no marked change has been produced. The probability is that if the joint is hypotonic it will always remain so. We simply tried to *correct the mechanical function of the joint and not its anatomic condition.* As far as the ataxia of the hands is concerned this is an entirely different proposition. The hand bears no constant weight, and this weight-bearing function of the foot creates the problem under consideration. The shoes have been worn by some of the patients about eight months. Drs. Schwab and Allison have found so much to learn and so much to correct that they can not say that the best sort of shoe has as yet been devised. The fact that the patients feel more secure the moment that they wear the shoes has been a constant observation. Some of the most important features of the shoes were suggested by the patients themselves.

THE WATER SUPPLY IN SHIPS FROM ITS BEGINNING TO THE PRESENT TIME.*

HENRY G. BEYER. M. D.
Medical Instructor U. S. Navy.
WASHINGTON D. C.

The problem of the water supply for sea-going ships is one of the most important and, at the same time, one of the most difficult to solve of all the problems of naval hygiene. It certainly is not a simple question. Ships can not always choose the source of their water supply. It may be impure or even infected to begin with. But even granting that it was faultless when collected, it may not remain wholesome during a long cruise.

The early efforts of the old sanitarians to provide faultless drinking water for seamen are full of pathos. Before the last century men did not know in what wholesome drinking water consisted. Much less did they know how to preserve it pure and sweet. When in addition to the ignorance of the age we find all efforts toward progress met either with cold indifference or active opposition, we may easily see why so little advance was made and feel a deep sympathy with the old ship's surgeons, Blane, Lind, Trotter, Fonssagrieves and many others in their fight against such obstacles.

To-day, with the help of chemistry and biology, the naval hygienist has come nearer solving the problem of a perfect water supply. While there are yet a few details to be perfected, we feel that they will soon be remedied and we, therefore look to the future with confident hope of success.

SOURCES AND COLLECTION OF WATER.

Until recently little or nothing was known about what drinking water should or should not contain. Of the two classes of impurities, organic and inorganic, the inorganic was the first to be investigated. About 1850 chemistry was far enough advanced to come to our aid and give us a few analyses of water. Later in the century biology helped us to discover the source of the more dangerous form of organic contamination and gave us means and methods for preventing the same.

A century ago, however, nothing of all this was known. The old sanitarians were influenced in the choice of water not by knowledge but by personal whims, a condition which even to-day has not wholly passed away. Neither chemistry nor biology has given us analyses that can be considered as generally applicable to all places and conditions at the same time. Different localities on the earth's surface produce waters of different compositions, and neither a chemical nor a biologic examination of a given water may be of any great value without a local inspection of its source. When we, moreover, consider that it is the proper and judicious interpretation of all the data involved that can give us an adequate idea of the nature of a water, we ought rather to be surprised at what the old sanitarians did know than at what they did not know.

Dr. Gilbert Blane,[1] for instance, tells us that "spring water is to be preferred to running or stagnant water," saying "unless it is taken at the source or near it, it is apt to be impregnated with decayed animal and vegetable substances, such as grass, wood and dead insects. This is an inconvenience that is greatest in hot climates, where everything teems with life and where materials of putrefaction are both more abundant and more prone to corruption."

That the greatest danger was hidden in the organic impurities of water was already well known in the midde of the eighteenth century, at least to Blane, we have a right to infer, for he says of that kind of impurity that "it is the most pernicious impurity" and that "the mineral impregnations common in springs are seldom in any degree unwholesome and do not, like the other, make the water corrupt." These are certainly correct observations and would pass muster to-day. The great and urgent necessity in those early times of navigation to procure a good and wholesome drinking water for a ship, in most any part of the world, sometimes took those old sanitarians far afield to inspect any lake. brook, spring or well that offered such a supply and made them practically acquainted with the natural sources of water the world over.

That meteoric water was at least in part depended on for furnishing a supply of drinking water, is perhaps easily understood, and may, moreover, be gathered from the early writers. Thus, Captain Cook, during his memorable cruise between 1772 and 1775, during which it is said that he lost but one man from disease, attributes to rainwater the swelling of the glands of the throat, and Gautier says of glacier water that it is very unhealthy. But Saussure already has called attention to the fact that the people in the high Alps, as well as the Esquimos, known to consume water from melted ice and snow, were essentially healthy peoples; and Wilson[2] says of rainwater : "When carefully collected, kept for a week or two in an iron or brickwork cistern, until its organic matters are decomposed, there is probably no better drinking water to be obtained." The explanation of all this is, as we know now, that rainwater, especially when collected in mid-ocean, is essentially a distilled water. While free from positive contamination, it never contains mineral salts to make it palatable.

One danger not sufficiently recognized in the early days of navigation is becoming better appreciated in recent years. That is the danger from contamination of water during its transport from shore to ship. A water perfectly pure and wholesome at its source may, by the time it reaches the ship or the sailor's stomach, be totally the reverse. Water, no matter from what source, must be taken to the large ships by a water boat. Barrels, wooden or iron tanks, earthenware vessels or even open rowboats may intervene between the natural source of supply and the scuttle-butt, with all the chances of contamination which such transport suggests. It is useless to say that, in these days of distilled water, these methods are no longer in practice. Every naval surgeon knows that a cruising ship will often take water from shore and fill its tanks with it, whether it is merely feed water for the boilers or not. These same tanks are used again for drinking water and consequently can remain safe from infection only when none but pure water is allowed to be stored in them. Again, every cruising ship will now and then get into places in which the most primitive methods of watering a ship are the only resource.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] "Observations on Dis. of Seamen," 3rd Edition, London, 1799. p. 297.

[2] "Naval Hygiene," by Joseph Wilson, M.D., U. S. Navy, Philadelphia, 1879.

The usual method of examining water after it had reached the side of a ship in a water boat was merely perfunctory and of no practical value whatever. A sample of it was indifferently collected in a tumbler or tin vessel by a messenger boy and sent to the apothecary for examination. The only test applied was the nitrate of silver test for chlorids and the water was pronounced good or bad in proportion to the turbidity being much or little. Better training of naval surgeons in methods of hygienic water analyses and a more liberal supply with the means to carry them out on board ship have wrought great changes and improvements within recent years. But unless the naval sanitarian watches every step which the water takes from its source of collection until it finally reaches the tanks of his ship, he can form no adequate idea and make no trustworthy report as regards the quality of the water collected. No chemical or bacteriologic examination will give him data sufficient to make a complete and sufficiently reliable report on the quality and fitness of the water in the ship.

STORAGE OF WATER.

The storage of water on board ship dates from the time when ships first took to the high seas and went out on long voyages away from land. For short voyages in small boats little water was needed and the time of storage was short. This small amount was kept in earthenware vessels, and even to-day this is the favorite and handy means of keeping small amounts.

For long voyages, however, where the crews are large, this method is inadequate and wooden barrels at first took the place of earthenware jars. Notwithstanding the fact that water thus stored became putrid after a while, this antiquated method of storing endured over 200 years. Putrefaction was expected to occur as a matter of course and was so universal on shipboard that sailors had the common superstition that water had to putrefy three times before it became drinkable. No one ever succeeded in preventing this putrefaction of water stored in wooden casks or barrels.

That the wood of the barrels out of which the casks were made had something to do with putrefaction of the water stored in them was well known to the old, observing sanitarians, who had various ways of treating these casks so as to preserve the water in good condition. Says Blane,[1] "The purest water is apt to spoil by producing a putrid glare on the inner surface of the cask which contains it. There is a great difference in this respect between a new cask, especially if made of moist wood, and that cask which has been hardened and seasoned by age and use. Several contrivances have been proposed for preparing casks that hold water, but none have been found by experience so effectual as letting them stand for some time full of sea water, and it is a great advantage of this method that it is so easily practicable." And then he continues to say: "We consider all water kept in wooden vessels as more or less liable to putrefaction, but there is a substance which is neither rare nor costly that effectually preserves it sweet. This is quicklime, with which every ship should be provided in order to put a pint of it into each butt when it is filled."

"It is probably owing to the small amount of quicklime found in Bristol water that it is so incorruptible. It has the advantage of not being injurious to health but, on the contrary, is rather friendly to the bowels, tending to prevent fluxes." Finally, he fortifies his recommendations by experience, saying: "In the year 1779 several ships of the line arrived in the West Indies from England, and they were all afflicted with the flux except the *Stirling Castle*, which was the only ship in which quicklime was put into the water."

Blane explains the action of quicklime by the destructive property which it has on animal life and on the "glare" that collects on the sides of the cask, as much as on a species of vegetation of the order called algæ by the naturalist. He also speaks of alum, cream of tartar, vinegar, vegetable and fruit juices and tamarinds as having been made use of. He relates, among others, that the fleet under Sir Charles Saunders found that the waters of the St. Lawrence produced fluxes and that this quality was removed by throwing in four pounds of burnt biscuits into each cask before it was used. But he adds, "there is nothing so effectual and subject to so few inconveniences as quicklime." Thomas Trotter,[3] after treating on diet, remarks: "We can not leave the dietetic part of our work without adding some remarks on water. We were employed the whole summer of 1792 in making experiments on the best method of preserving water pure and sweet in long voyages, and a summary of this is published in a later work called 'Medical and Chemical Essays,' printed by Jordan, Fleet street, for Mr. Maubray of Portsmouth, to whom I presented a copy at the time his printing office and materials were burned, in December, 1794. We found, after trying everything, that the best practicable method was gently charring the casks in putting them together, both staves and heads, which rendered the surface unfit to decompose the water. But so little was this practice deemed perfect by the victualling board that Mr. Reeks, the cooper at Weevil, showed us an order from the commissioners expressly forbidding it, as they said it blackened the fluid." Then he continues: "It, moreover, makes the casks last longer by hardening them against worms in hot countries and also less liable to shrink from the hoops.. The whole process," he says, "is dependent on chemical principles in the above work and no one has dared to say that they are wrong." "I now, in the name of the service, request some captains to take the business up and carry to sea a given number of casks filled with pure water, one-half charred according to our way and the other half in the common way. Some trusty person must superintend the duty that it may be fairly tried, for we know it must succeed."

PRESERVATION OF WATER.

Nowadays, none but a few fishermen perhaps use the wooden casks for water. Since we can not and will not wait for our water to become thrice corrupt, as the old saying was, some shorter means had to be found. It was becoming more and more recognized that the method of storage had to be improved in order to preserve water sweet. The otherwise good effects of charring having proved of merely temporary benefit, sulphurization was tried and found better. The manner after which sulphur was used is as follows: The sulphur was burned in the barrel and then the barrel was filled one-fourth of its capacity with water, then some more sulphur was burned and the barrel filled half full of water, and so on until the barrel was full. Then, for every ten liters of water twenty drops of sulphuric acid was added and the barrel covered up. Such water, though with an acid taste, was not disagreeable to drink.[4] Then the addition of oxid of manganese was attempted in the proportion of one gram to 150 liters, as had been recommended by Perrinet. Although this process gave the water an acrid, rather astringent taste, it was inoffensive, more expeditious and much easier carried out than sulphurization. In 1822 four barrels of water were treated in France, two by charring and two by addition of oxid of manganese. After 33 months the water in the former two was found to be in a putrefying condition and that in the latter two was found good to drink in spite of its taste. The facts could not be denied and every one had by this time come to recognize that all efforts to render wooden barrels a fit means for water storage had miserably failed in one way or another. Recommendations for substituting iron casks for wooden barrels were first made as early as 1739 by Sibon, a captain at the port of Toulon,[5] while General Bentham is said actually to have introduced iron casks into the British navy in 1798, after previously experimenting with them for years. This was done later also in the French navy, and the cruiser *Uranie,* fitted out to go on a scientific expedition, was the first ship of the French navy supplied with iron tanks alone.

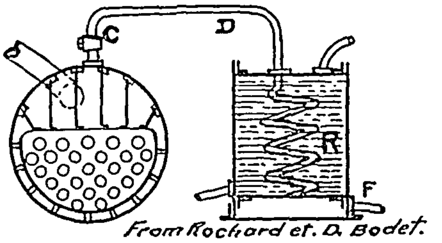
[3] Trotter, Thomas, M.D.: Medicina Nautica, London, 1804, vol. II, p. 167.



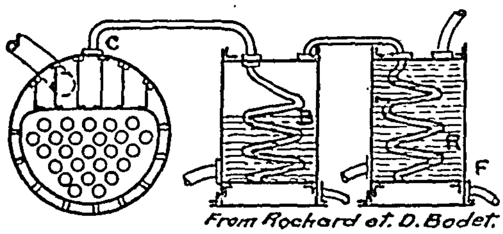
From Rochard et. D. Bodet.

Fig. 1.—Distilling apparatus of Rochard and Bodet.

This does not mean, however, that the practice became universal immediately. On the contrary, it spread very slowly, indeed, for we have in our own navy a fairly recent record of the use of wooden casks down to the latter part of the last century. Rear Admiral G. W. Baird,[6] U. S. N. (retired), writes me that the sailing sloop *Constellation,* of 1,186 tons displacement, carrying a crew of 228 men, had 48 iron tanks and 124 wooden casks, containing 32,364 gallons, 120 tons of water. The amount of space which these water casks occupied is shown in the further statement of Baird, when he says: "The 48 iron tanks alone weighed 31 tons, there being no record of the weight of the casks. In this ship it will be seen that a little over one-eighth of her total displacement was taken up in the water supply." The delay in the introduction of iron tanks must be attributed to two principal causes: (1) In prebacterial days no satisfactory explanation could be given for the occurrence of putrefaction in wooden barrels, and therefore no good reasons seemed to exist why the same water should not putrefy in iron casks as well as in wooden vessels. It was not recognized and, consequently incredible that the source of putrefaction consisted in bacterial action on sulphates contained in the water. Now that we know of sulphur bacteria engaged, on the one hand, in reducing sulphates to sulphuretted hydrogen, and in oxidizing the latter to sulphates, on the other, we can better understand at least one of the causes of this trouble and how the porous wooden walls became the culture plates for that class of organisms. (2) The other reason is that iron casks, although a great improvement over wooden barrels, also had their serious objections themselves. One of these was that they were expensive and the other was that the iron was quickly oxidized and the resulting rust deposited in large quantities. The iron rust that forms as a result of the direct contact of pure water with the unprotected iron plates is at first deposited; when the ship gets under way it becomes suspended in the water. When we add to this the heat of a tropical climate and of a hot ship, a drink of such water, it may easily be imagined, is not very refreshing, to say the least of it.

According to Rochard et Bodet,[4] from 8 to 10 kg. a year were collected from a single tank.

Since it was, moreover, not indifferent for the health of the consumers whether a water did contain iron rust or not, means had to be taken to prevent the water from coming in direct contact with the iron, thus keeping the tank from being eaten up and the rust from getting into the water. After experimenting with various kinds of gums and gum resins, with lead and zinc linings and coating the walls with lime in more modern times, the most commonly employed material to-day and the least objectionable for lining these tanks is Portland cement.



From Rochard et. D. Bodet.

Fig. 2.—Distilling apparatus showing special condenser.

In lining the tanks with cement, various additions to the latter have been recommended. Thus, Sestini recommended that chalk be added to it; but this resulted in a very hard water. The best and simplest process is that recommended by Lefèvre and is as follows: The sides of the tank are thoroughly scraped with a metallic brush to free them from rust. This is followed by flaming the sides with a soldering lamp. After flaming, the best Portland cement, made into a convenient consistency, and prepared with boiled water, is applied with a soft brush and allowed to set perfectly; several coats may be applied if necessary. After the cement has hardened, the tank is ready for use. Such a lining, it is claimed, will last for two years. Chalk, to say the least, is unnecessary. We may conclude, therefore, that the problem of preserving water on board ship is provisionally solved and that iron tanks with a cement lining will be used in the future on all ships of the navy as in those of the merchant marine where the vast importance of a good, wholesome water is recognized and appreciated.

WATER CORRECTIVES.

Imagine seamen in the early days of circumnavigation, far away from land and pure water with nothing but bad water to quench an ever-recurring thirst. We cannot wonder that they should try by every means conceivable and inconceivable to improve their drinking water. We, therefore, find a host of remedies for bad water some of which even anticipated the methods in use to-day. Says Blane, writing in the latter part of the 18th century: "When the water of wells or brooks is found loaded with mud, the following expeditious method of filtration, described by Dr. Lind, has been practiced with success: 'Let a quantity of clear sand or gravel be put into a barrel placed on one end without the head so as to fill one-half or more of it and let another barrel, with both ends knocked out, of a much smaller size, be placed erect in the middle of it and almost filled with sand or gravel. If the impure water be poured into the small barrel or cylinder, it will rise up through the sand of the larger one in the interval between it and the small one.'" In this description, we can see, without a great stretch of the imagination, the germs of the construction of a modern well or of the present method of sand filtration, if not of the Pasteur-Chamberland candle. Again, with regard to aëration, Blane says: "Such is the attraction of the air for this offensive matter that the water need only be brought thoroughly in contact with it to be rendered quite sweet." Then he describes an apparatus invented by a Lieutenant Osbridge. With this apparatus the water in the cask was raised a few feet and allowed to fall through several sheets of tin plates perforated like "colanders" and placed horizontally. Blane speaks of it as "a machine very deservedly in common use and the working of it is a modern and salutary exercise to men in fair weather." Thus we may take it for granted that, besides filtration, these old sea sanitarians knew well the effects of aëration as far back as 1750.

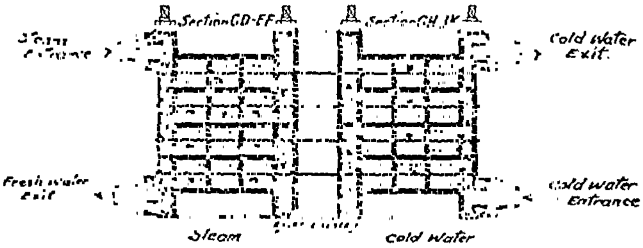

Fig. 3.—Pape and Henneberg condensor.

At that time the water they had to deal with was presumably full of decaying organic matter. These old wooden casks were indeed nothing more nor less than what we now conceive to be septic tanks and in the conditions under which these tanks were kept, down in the bottom of the ship, dark, damp and mouldy places, poorly, if at all, ventilated, the anaërobes must have led an ideal existence. Consequently, aëration produced an improvement almost startling.

DISTILLATION OF WATER.

Among all the numerous water correctives, distillation requires a special treatment, on account of the large and important part which it always played in connection with the water supply on shipboard. It is now well recognized that at least one of the reasons why distilling of sea water did not become more quickly popular than it did, was the firm belief entertained at that time—and still entertained by some of the present day—although for better reasons than of old, that something had to be added to it before distilling was begun, so as to "remove the spirit of salt." It was perfectly well known to Dr. Lind and to his sympathizing contemporaries, however, that the distilling could be done without adding anything to the sea water to begin with. Says Lind:[7] "In 1761, I had publicly demonstrated by various experiments at the Royal Academy at Portsmouth, that a simple distillation rendered sea water perfectly fresh, pure and wholesome. These experiments were made in the presence of Mr. Hughes, resident commissioner of the navy at that port, and of Mr. Robertson, late master of that academy. In the month of May, 1762, an account of this discovery was read at a numerous meeting of the Royal Society in London; in March, 1763, the second edition of my essay on preserving seamen, containing this discovery, was published in London, by the authority of the Lords Commissioners of the Admiralty; which honor their lordships were pleased to confer on account of this important discovery."

Hauton, in 1670, is said to have recommended caustic alkali for the purpose of destroying the bituminous matter. Appleby, in 1734, published his procedure by order of the English admiralty, in which he extolled the virtues of caustics and calcined bones. Butler employed soapsuds. Walcot added antimonial preparations, while still others wanted to let the water putrefy before beginning its distillation. Lastly, Perrinet, in more recent times proposed the addition of manganese and charcoal in the proportion of 1:5000.

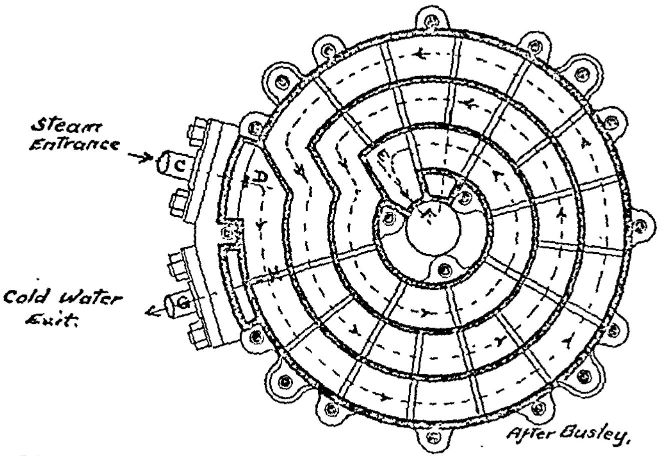

Fig. 4.—Pape and Henneberg apparatus, showing tubular arrangement of condensor.

While, then, the credit of having been the first to suggest and to carry out distillation of pure water from sea water is claimed by several individuals, it may be said that distilling did not come into general use before 1761, when Dr. Lind was fortunate enough to discover that sea water simply distilled, without the addition of any ingredient, afforded a water as pure and wholesome as that obtained from the best springs.

Even the discovery of the learned Dr. Stephen Hales[8] did not find general favor at that time, although received with considerable enthusiasm by some; so that, distilling may be said to have begun in earnest from the time when Dr. Lind's discovery became generally known. The earliest attempts at distillation were clearly not successful. According to Lefèvre[9] it was Gauthier of Nantes who constructed a distilling apparatus as early as 1717 and Dove and Hoffmann constructed one in 1765. Both these were rejected on account of being too cumbersome. The rudest kind of contrivances were at first devised. The stills in Blane's time, employed on English ships, are described as consisting merely of a "head and worm" adapted to the common boiler, and in which distilling was done, while the food was being cooked. More than eight gallons of excellent fresh water were said to have come off in one hour from the copper of the smallest ship of war.

---

[7] An essay on diseases incident to Europeans in hot climates. Philadelphia, 1811, p. 242.

[8] Stephen Hales, D.D., F.R.S.: "An Account of a Useful Discovery to Distill Double the Usual quantity of Seawater by Blowing Showers of Air up Through the Distilling Liquor." London, 1756.

An extemporized distiller by Dr. Lind is described as consisting of a tea kettle with the handle taken off, and inverted on the boiler, with a gun barrel adapted to the spout, passing through a barrel of water by way of "refrigeratory" or kept constantly moist with a mop. In 1763, Dr. Poissonier devised a distiller that could be adapted to the ship's kitchen and about the same time Irving in England devised a similar apparatus, both of which were received with great enthusiasm at the time.

The progress which the introduction of distillers made in the early part of the 19th century was destined to receive one more brief check. In 1817, Sage, in an impressive memoir, strongly protested against the general introduction of the distillers of Poissonier and Desormes into ships, claiming that distilled water was dangerous and demanding that new experiments be made before installing these distillers. To judge by what followed the publication of this memoir, it must have made a deep and widespread impression; it also indicates the general importance attached to the whole subject at the time. A series of experiments were at once begun on convicts. Water from the ports of Brest, Toulon and Rochefort was distilled and 41 convicts made to drink none but distilled water for a whole month. Behold! their health was found not to suffer in the least as a consequence of the water they drank. A captain and several other commissioned officers drank of the same water without injury to their health. After these experiments, the question raised by Mr. Sage of the existence of a poisonous "alkalino-oleagino-neptunien gas," according to Lefèvre, was finally decided against him. The end of this controversy was likewise the beginning of improved distillers for use in ships.

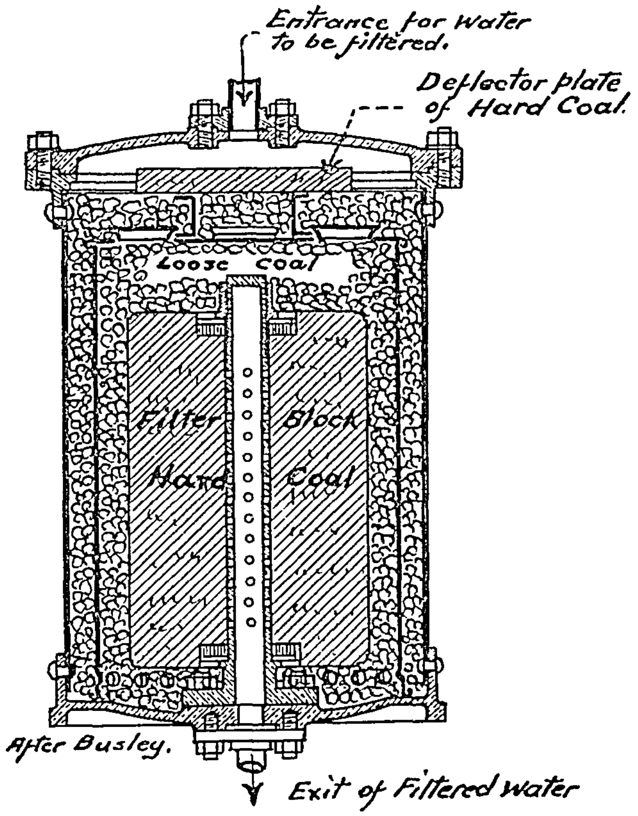

Fig. 5.—A filter of the best pattern showing how the water enters and is at once deflected by a carbon plate over loose pieces of carbon.

The distilling kettles consisted of quadrangular cases made of sheet iron, their interior being divided into three compartments by two horizontal partitions. The lower compartment was the hearth or furnace, the middle compartment contained the sea water to be boiled and distilled and the upper compartment was the place where the food was cooked by the steam generated below. Such a distilling kettle was surrounded on the sides by refrigerators through which ran a spiral pipe in which the steam was condensed.

Water Aerator and Cooler.
after Geo. H. Kearny U.S.N.
Fresh water supply from pumps
Fresh water discharge to tanks.

Fig. 6.—Showing aërator constructed by Capt. G. H. Kearney. U. S. N.

It is easily seen that the quantity of water furnished by these distilling kitchens was small and barely gave the amount of water necessary for drinking purposes. The demand for larger quantities was soon supplied by larger as well as better distillers. How slow their general introduction was, into the U. S. Navy in particular, is best shown in the letter from Admiral Baird, already referred to, as well as in the account of an improved distilling apparatus given by him in the *Journal of the Franklin Institute* for 1870 and 1872. The first serious attempt in the construction of distillers for use in the U. S. Navy was begun by him in 1866 on the *Pensacola,* and in 1877-8, I made a cruise on a sloop of war under sail from San Francisco around Cape Horn to Washington, a journey of 112 days, without a distiller of any kind on board.

For a long time, it was steam from the main boilers that was condensed to furnish potable water. The arrangement was of the simplest kind. One of these boilers was tapped and the steam escaping through a spiral copper pipe was cooled to condensation as may be seen illustrated in principle in Fig. 1. Such water, as might be expected, was almost invariably laden with all the impurities, not only of the sea water, but also with those from the inside of the boiler itself, especially fatty acids, which imparted to the water its well known empyreumatic odor.

Special distillers of greatly improved pattern were made during the latter part of the last century. The most notable among these were the Cousin, the Weis and the Mouraille in France, the Normandy, in England, the Standard Evaporator in the United States and the Pape and Henneberg in Germany. The general principles in the construction of them all is as follows: The sea water is conducted into a special reservoir where it is heated by steam pipes connected with one of the boilers from the main engines. The steam in this arrangement does not mix with the salt water to be evaporated, providing everything is tight, but, after heating the sea water which surrounds these pipes, returns to the main boiler whence it came. The evaporated sea water is condensed in a special apparatus called the condensor (Fig. 2).

Since all the most essential changes and improvements in the present distillers have occurred in that part of it known as the condensor, I may here limit myself to describing what is at present believed to be the best and most economical one in use, namely, the one designed by Pape and Henneberg of Hamburg, Germany.

The Pape and Henneberg condensor (Figs. 3 and 4) consists in a number of flat elements, each one of which is divided into two by a central partition on each side of which the spaces are arranged spirally. The cold water entered from below runs from the circumference to the center of the lower spiral chamber of the lowest element. Thence it rises through an opening in the separating plate up into the lower spiral chamber of the second element, through which it passes from the center to the periphery. From here it proceeds to the lower chamber of the third element and so on until at last it makes its exit from the lower chamber of the upper element. The steam to be condensed, entering above, takes the opposite course, running through the upper spiral chambers of each element in succession, giving off its heat to the cold water, through the thin copper plates (dividing the two chambers), until it issues as water below. The process of the steam's parting with its heat is further favored by the chamber's floors being traversed by ribs, which arrangement causes the steam, as well as the water, to be constantly stirred. It is stated by Busley[9] that the caloric effect of these condensors is almost from eight to nine times as great as that of the ordinary tubular surface condensors. Thus in a condensor of four plates and a cooling surface of 0.56 square meter, the hourly product per square meter surface, is the conversion of 270 Kg. of steam of 116.290 C. into water of 13.60 C. in which is only 2.9 C. warmer than the water used for cooling purposes. (Figs. 3, 4 and 5.)

AERATION AND FILTRATION.

In some of the smaller gunboats and other naval vessels that are unprovided with the refrigeration plant and have but a small tank capacity, it often happens that the distilled water does not remain in the tanks long enough to get cool and the drinking water must be consumed while yet warm. This is especially often the case in tropical climates, just where a cool and refreshing drink of water is most gratefully appreciated. Under such conditions aërators are very desirable.

Figure 6 is intended to show an aërator constructed by Chief Engineer (now Captain) George H. Kearny, U. S. N., according to my ideas, and later, much improved by him installed on board the U. S. S. *Marblehead.* A small pump takes the water from the distiller to the top of the tower where the water drops in succession through a series of perforated copper discs, and, in this manner, becomes cool and aërated. At the bottom, the tower opened into a larger receptacle which served as a reservoir and from which the water was sent either into the tanks or into the scuttle-butt. This aërator did excellent work both as regards aëration and cooling. On board the *Yantic* the men spoke affectionately of their water tower, but my sudden detachment from the ship did not give me time to make the observations I had planned to. The illustration here shown lacks the double cylinder which was intended for the aërator to be installed on board the U. S. *Yantic.* There was to be an air chamber between the inner cylinder through which the water descended and the outer cylinder, to protect the water from the heat of the sun. The openings through which air was admitted to the tower were protected, moreover, by several layers of flannel to remove the dust from the entering air; this also is not shown in the figures.

How carelessly, in former times, some of these aërators were made and used is shown by an incident in my experience in 1890. Shortly after reporting for duty as medical officer of the U. S. S. *Yantic,* in 1890, the unusually large sick list and the nature of the complaints led me to examine the drinking water. This was found to contain organic matter and chlorids in large amounts. The commanding officer insisted that the water was distilled and could not be the cause of the illness. The trouble, however, was promptly traced to the aërator.

The aërator in use at that time consisted of a wooden box about 6 ft. long, 1½ ft. high on one side and ½ ft. wide. The box stood on deck with one of its sides against the engine room hatch; the distilled water entered at one end and passed out at the other, presumably cooled and aërated. When the men were washing the decks, which was done with salt water drawn up in buckets from over the side of the ship, dashing the salt water along the deck, large amounts of it were thrown into the aërator. When it was realized that the *Yantic* was at that time alongside the wharf in the navy yard of New York near the Simpson Dry Dock within 20 ft. of a large privy and urinal, not to speak of the sewers of Brooklyn, no more proof was needed. Suffice it to say that one demonstration of this kind convinced the commanding officer that this aërator was the efficient cause of both the bad water and the sick list and the antiquated piece of apparatus was abolished and the one, described above, put in.

Air injectors and carbon filters were at one time thought to be necessary parts of distillers. The air injectors were usually interposed between the evaporator and the condensor into which latter the air was introduced while the filter was placed between the condensor and the water tank. These injectors seem never to have made good their claims. With the latest distilling apparatus an oily taste in the water can be avoided and the filters of any kind do not seem to remove that taste when present; with our increased experience and knowledge of the means of distilling sea water in ships, even the carbon filter will probably soon be discarded altogether and pass out of use.

---

[9] Busley, C.: Die gesundheitlichen Einrichtungen der modernen Dampfschiffe, Berlin, 1897.

Figure 5 shows one of these filters of the very best pattern. Here the water enters above and, being at once deflected by the carbon plate over the loose pieces of carbon, is distributed through the outer chamber; from here it passes into the inner one and after traversing the inner chamber and the solid carbon block, it runs directly into the tank through the ordinary pipe connections, awaiting its further distribution to convenient places by small steam pumps. The Chamberland filter, after but a trip trial on board ship was given up as impracticable.

According to Plumert[10] the one filter possessing the greatest advantages and the least disadvantages for ship's use, is the micro-membrane filter of Kregor of Vienna. Such a filter is said to furnish 500 liters an hour. But the problem at present before us is to provide such a water by distillation on board ships that does not need to be filtered and, such a water can now be furnished with our present distillers when these are properly managed.

Thus, our experience with peripheral filtration on board ships has resulted similarly to that on shore. The observations of Hesse and Plagge, those of Woodhead and Wood and of Freudenreich and Schöfer have shown that peripheral filtration is, to say the least, not absolutely trustworthy. According to Frankland, Woodhead and others, it was shown that charcoal especially adds to, rather than detracts from, the number of germs after it has been used for some time. This is exactly the general experience with such filters on shipboard; and when the injectors had poured volumes of dust into them, such filters proved to be veritable culture media for germs. All these objections become, of course, accentuated in the tropics.

In a recent article by Le Méhauté,[11] that author wants the air injector to be abolished because of being both useless and dangerous; useless, because the water may be trusted to aërate itself; and dangerous, because the injected air introduces myriads of germs, the nature of which cannot be controlled, although granting that for the most part they consist of non-pathogenic saprophytes. Le Méhauté, moreover, deems the carbon filter superfluous. At one time, says he, it answered a purpose; namely, that of removing particles of lead and greasy matter. Now, since these dangers no longer exist, the filter has become unnecessary.

(To be continued.)

[11] L'eau potable a bord. Arch. de Med. Navale, 1904, Nos. 9 and 10.

Arthritis Deformans.—A characteristic deformity of the foot, says Billings, is a permanent hyperextension of the proximal phalanges, with flexion of the distal bones of the toes. The distal ends of the metatarsals become prominent and tender and make the foot tender, and walking painful and awkward. In most cases, says McCrae, the glands near the affected joints are enlarged. Heberden's nodes, at the terminal phalangeal joints of the fingers, may occur alone or with involvement of the larger joints. The joint (or joints) once attacked seldom clears up suddenly, and the disease, unlike acute articular rheumatism, rarely shifts from joint to joint. The pulse is nearly always above normal. There is rapid muscular atrophy and exaggeration of reflexes. Chronicity is very suspicious of this disease. A highly nutritious diet, arsenic and syrup of iodid of iron are chiefly indicated.—*Denver Medical Times.*

PRESENT DAY METHODS OF CONDUCTING LABOR CASES AND THE RESULTS OBTAINED.*

JOHN A. McKENNA, M.D.
Assistant Surgeon, Medico-Chirurgical Hospital, Philadelphia.
LANSDOWNE, PA.

I selected this subject for presentation before this section because of the great interest obstetric work holds for me among the several branches of medicine with which I am familiar, and because of the gratifying results I have obtained in this line of work.

I have not attempted a critical review of either ancient or modern obstetric methods, but have made the body of this paper a report of my technic of delivery, an analysis of a series of cases which have occurred in my private practice and some few other cases seen in consultation.

Among the splendid activities by which tireless science keeps mankind ever moving forward, it is not often that the obstetrician claims public attention by sensational discoveries or achievements; yet in the broad domain of human progress there has been no more distinct or radical advancement than in that field which calls for the highest resources of both the great branches of medicine.

It is interesting to note in passing that while at one time some disposition was shown to include or to absorb this study under the term of gynecology, there are institutions and professors, among the most learned and eminent, that insist on calling it by the old name of midwifery, although this term bears little more relation to what the science has become than the spiral white and red ribbon of the barber's pole does to the surgery, or rather to the phlebotomy, that the "tonsorial artist" now practices without an anesthetic.

It is within the lifetime of those who would not like to be classed among the aged that the observant Semmelweiss decided that all students assisting in the lying-in wards of his Vienna maternity hospital must wash their hands in a "disinfecting" solution of chlorid of lime, and thus within a year obtained a conclusive demonstration of the truth of his theory in the notable lessening of mortality (which had been as much as 30 per cent. or more in some months) among the puerperal patients of the institution.

The question often asked in regard to corelative subjects recurs when we perceive how apparently meager were the resources of our progenitors in the matters of midwifery. How did they get along without the skill and knowledge which the modern practitioner now has the opportunity to acquire? Putting aside the more or less untrustworthy and fantastic excerpts gathered from the Chinese medical writings ascribed to a period of five thousand years ago, we have the Ebers papyrus as the probably oldest authentic medical writing extant. In that document, written fifteen and a half centuries before Christ, there is next to nothing given for enlightenment or help in labor cases, and more than one thousand years later we find the Father of Medicine correspondingly silent in the Hippocratic writings, except in one instance.

There is historic warrant, however, for the presumption that, somehow or other, the increase and multiplication of the human race went forward along the ages in accordance with the Divine command, notwithstanding the absence of professional advice, direction and assistance. Incredible as it seems in our day, it was late in the sixteenth century, when royalty set the fashion of having court surgeons attend parturient ladies, that midwifery began to make strides in scientific advancement Before that time, as Simpson observes, "Physicians and surgeons had been summoned to the lying-in room only by midwives who found themselves at the end of their resources, to give help in difficult cases, when the child was usually dead and the mother moribund."

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association at the Fifty-sixth Annual Session, July, 1905.

I regret that this paper may be open to suspicion of indelicacy as to its implication of egotism, but I feel that to this I only need to enter a simple disclaimer. Though still classable as a junior practitioner, I have had within a period covering some seven years in private practice 207 confinement cases, not only without a fatal issue to either mother or child, but without, as yet, a single development of any of the forms of grave puerperal troubles which eventually beset every obstetrician, such as sepsis, hemorrhage, eclampsia, severe laceration, etc.

I am glad to believe that there are many of my colleagues who could make the same satisfactory report, but I know on the other hand results have been different with many others. This latter fact is at once my apology and warrant for this paper.

In The Journal of the American Medical Association, April 15, 1905, occurs the following abstract from a paper by Dr. Lea,[1] and in order to economize time I will let the abstract of Dr. Lea's report stand as typical for this paper.

> The method of treatment adopted by Lea is based on 120 cases. He says a rise of temperature to 101 F., not accounted for by other causes, renders a careful examination of the generative tract necessary. If no sufficient cause is found in the vagina or perineum, and if the uterus is bulky and tender, a specimen of the lochia is removed and a uterine douche given, with due precautions. In 48 consecutive cases this was sufficient in 30 per cent. to bring down the temperature rapidly to normal. For some years Lea has supplemented this by careful swabbing of the interior of the uterus with absorbent wool soaked in a solution of biniodid of mercury in alcohol, 1 in 2,000. If this procedure is inefficient, or if the infection is severe, from the first, the uterus is explored with the fingers, preferably under chloroform anesthesia. If the cavity is perfectly smooth, showing an absence of retained products or of decidua—a condition which is rare—the uterus should be thoroughly swabbed out with the biniodid or some strong antiseptic solution, and packed with iodoform gauze soaked in an antiseptic. If a piece of placenta is found this should be removed, followed by swabbing and gauze packing. If the cavity is large and the surface irregular, due to hypertrophied and necrotic decidua, the patient's safety can only be insured by its complete removal. This is most efficiently done by the use of a suitable curette. Vaginal section may be done as supplementary to curettage if symptoms of pelvic peritonitis are present. If the uterus contains placenta or débris, accompanied by grave infection, hysterectomy is much more dangerous than curettage, and packing should never be done. The best results from hysterectomy have been obtained in cases of periuterine suppuration, gangrene of the uterus, or necrotic myomata.

Here are statistics, advice and methods of procedure that to me are appalling. While my obstetric experience besides Dr. Lea's is, of course, lilliputian, I am sure that had I made digital examinations and had given uterine douches to my puerperal patients whose temperatures had gone to 101 F. and over, I certainly would have had infected cases about which to compile statistics.

I have followed this rule in labor cases: Let nature do as much as possible in these cases and only do that for the patient that nature seems unable to do. Briefly, my conduct of a labor case has been to insist as far as possible that everything should be scrupulously clean about the lying-in room as regards dressings, instruments, utensils, bed linens, etc., to make no vaginal examinations unless the external parts have first been cleansed with soap and water, to swab out the vagina with a gauze sponge, and thoroughly to coat the finger nails and hand with soap, after washing them and rinsing them in ether; to deliver all patients in the dorsal position, to support the head and perineum by a modification of Merkerttschiantz's method, which reduces lacerations to a minimum, and, what I deem most important, to have the fundus of the uterus grasped before the presenting part is born, and firmly held until the child is delivered and the cord tied. This procedure, I am convinced, has prevented in my practice a single post-partum hemorrhage of either great or small degree, and has facilitated the delivery of the placenta in the great majority of cases in from one to three minutes after the cord has been tied. In addition to the above routine, no douches, vaginal or uterine, were given to any cases, either before or after labor.

Where a vaginal or perineal tear occurred, and was sewed, the apposed edges of the wound were carefully swabbed once to twice daily for the first few days with a cotton or gauze sponge to remove the exudate. I have deemed the vaginal and uterine douche of as questionable value in labor cases, as I found it to be in abdominal surgery, and have therefore to date tabooed it absolutely, and I believe that I have obtained results which sustain my radical views in this respect, for I have believed that more infective matter may be put into the vagina and uterus by the douche than the flushing will bring away.

The several patients known or supposed to have had a recent gonorrhea I treated locally for some weeks before labor began by dilating the vaginal folds frequently and swabbing thoroughly and in a painstaking manner with a strong solution of one of the albuminates of silver. Although some rather severe lacerations have occurred, none has ever extended to or near the anus, and in no tear have more than two stitches been applied.

I am aware of three cases in which small pieces of placental mass were retained in the uterus, but for which nothing was done save to watch the condition of the patients. Two of the patients passed the placental fragments the day following delivery, but the third woman did not discharge the retained placental portion until the fifteenth day after her confinement, when she passed a mass of tissue as large as an egg, with an extremely foul odor. From the fourth day of her confinement the lochia had an offensive smell, and as the placental mass was known to be in the uterus the cause of the odor was known. As the woman's temperature never went above 100.3, nor her pulse above 94, I did not interfere in the case, for I believed that fermentation of the placental mass caused the odor, but the lack of abnormal temperature or pulse pointed to the absence of any extremely virulent bacilli; however, had I with a curette broken into the natural barrier of the uterine walls, I would not have been surprised if the woman had developed a severe or fatal sepsis.

Of forceps delivery I can say but little, having used these instruments but twice since leaving a maternity hospital service shortly after graduation, once in an R. O. P. and once on a primipara aged 39 years, with inertia.

---

[1] "Some Remarks on Puerperal Infection": A. W. W. Lea, British Medical Journal, March 18, 1905.

Often it has been most embarrassing and annoying to find hour after hour slipping away and only slow progress being made, when the application of the forceps might have freed me from a long, tiresome wait, but the mother's condition, fortunately, has always warranted a delay, and I have thus refrained from using this mechanical aid which has done so much good for the puerperal woman, but which, if used, when not absolutely called for, has entailed serious injury to mother and baby and sometimes has caused the death of both.

I am sure that if a longer time were given the patient in labor in which to allow normal progress to be made and simple manual aid given the mother during the pains, statistics of puerperal lacerations, sepsis and death would show a marked decline.

Complications in my series of cases were surprisingly few. In one case seen first at term, I extracted a five-inch section of an olivary tipped bougie, forced into the body of the womb four months before in an unsuccessful attempt to bring on a miscarriage. The woman made an uneventful recovery.

One woman was delivered during the second week of a severe attack of typhoid fever, labor being hastened by the approaching crisis of the disease. The child was as healthy as most babies are at birth and the mother stood the shock well; when the child was five weeks old the mother insisted that she was strong enough to give the baby breast nourishment, artificial feeding having been employed in the meantime. The change was successful and the mother and child thrived. I was unable to get a positive Widal reaction from the mother's milk on the baby's blood, although the mother's blood gave the positive Widal.

Another patient was confined on the fifth day of a lobar pneumonia with a temperature of 104, and pulse 140. Her fever fell to subnormal on the second day after labor, and although very ill for several weeks she recovered. The baby was fed from the bottle and did well.

The anomalies of the cord and placenta were the common ones described in obstetric text-books, and lack of time prevents their description.

In about three of the above series of cases the patients had fibroid uteri of a moderate degree and in one case I delivered a syphilitic woman of a full term macerated baby, dead probably a month, and a live baby of probably six months' development, which lived for three weeks. There were separate placentæ. The woman had been taking specific treatment for about six months previous to her delivery.

A deplorable case I saw in consultation. A woman had been in active labor for three days with an immense cancer of the cervix. Her physician insisted that her condition was due to a "rigid cystic os" and refused to allow any interference with the case, operative or otherwise. The woman died of exhaustion on the fifth day after repeated attempts of her physician to apply forceps through the cancerous mass.

The fact to which I would call particular attention is one which is, perhaps, oftenest a source of extreme danger, and is too seldom recognized and guarded against. It is this: Just as special circumstances may convert stomach, bladder or colon into a veritable septic center, the position assumed in bed by the greater number of puerperal patients almost inevitably improvises, as it were, just such a septic cavity quite susceptible of infection, for the more yielding the couch the greater will be the pocket formed, as the patient unwittingly burrows into the bed at the spot where least resistance conjoins with that of her greatest weight. In this depression septic fluids in the bed or stagnant in the vagina are an ever present source of danger to the open uterus with the cervix resting on the vaginal floor, making the entrance into the womb only too easy for infectious fluids. To obviate this I keep the patient's hips well raised from the bed during the whole course of labor, and the vagina is thus kept free from any return flow of liquids contaminated by contact with the pad or bed.

With the field of obstetrics expanded into or supplemented by the gynecology of the day, the ideal combination of physician and surgeon may now find in obstetrics opportunities virtually illimitable for the worthiest and most useful exercise of his talents and skill, for it embraces the whole scope of theory and practice affecting the health and lives of women and their offspring. Even the modest average practitioner, if of the proper grade of intelligence, may enter it with confidence. In either case, to repeat a trite, but never needless, suggestion, it will be found that "soap and water and a good hand brush," with all that this implies will be important essentials for success.

DISCUSSION.

Dr. W. A. Shannon, Seattle, declared that all obstetric cases should be treated like surgical cases, and the same precautions taken as in a surgical operation. Then there will be very little trouble with these cases. Dr. Shannon has for some time adopted the method of wearing rubber gloves during his obstetric work, believing it to be eminently proper. A physician is apt to be in a hurry to get away from the house and is likely to extract the placenta too early. He should wait at least twenty or thirty minutes after the birth of the child before expelling the placenta. The external genitals should be scrubbed thoroughly at the beginning of labor, shaving the parts, if necessary. The patient also should be prepared as if for the repair of a lacerated perineum.

Dr. J. A. McKenna said that he has tried rubber gloves and found them in the way and even risky, inasmuch as he could not control the perineum nor make proper traction on the cord while wearing them. He always expels the placenta, or attempts to, as soon as he ties the cord. If the nurse has grasped the uterus properly from above, the placenta will be ready to be expelled in 95 per cent. of the cases as soon as the physician is prepared to deliver it. Nor are the after pains so severe if the uterus is held and the cavities in which blood clots may develop not allowed to form.

SUPERIOR ACCESSORY THYROIDS.*

JOHN B. MURPHY, A.M., M.D.
Professor of Surgery, Rush Medical College.
CHICAGO.

Some writers call the accessory thyroids, "lingual goiter." The term "goiter" given to such affections is an improper one, since the histo-pathology shows that not all aberrant or accessory thyroids have the structure of a goiter, which implies a pathologic thyroid. In several instances the histology of the accessory gland was exactly the same as that of the normal thyroid.

---

* This article was prepared to be read before the Section on Surgery and Anatomy of the American Medical Association at the Portland session, July, 1905, but the author was prevented by sickness from being present.

Perhaps, even the term "accessory" is not proper, since in some cases, as will be seen later, the so-called accessory thyroid was the only one of the individual. Aberrant thyroids would be the most satisfactory term, indicating a thyroid situated outside of the normal area. For the sake of convenience, however, I will respect the term "accessory" generally used in the description of these tumors. While anatomists, and even pathologists, are more or less familiar with the accessory thyroid, the clinician has rarely an opportunity to meet such tumors. On account of their very rare occurrence, and because of the grave and even fatal errors that might result from the lack of information concerning such tumors, the study of accessory thyroids must be of interest to every surgeon.

HISTORICAL.

Accessory thyroids were known to the old anatomists. Albert von Haller (1779) once saw an accessory thyroid occupying the middle of the thyroid cartilage, and not connected with the thyroid proper. In 1839 von Haller referred to accessory thyroids. Gruber[1] found the isthmus separated from the thyroid and located above it in 2 out of 40 cases. In 1853 Verneuil,[2] while dissecting the muscles of the tongue, found a sessile body the size of a pea situated between the geniohyoid and genioglossus. It proved to have the structure of a normal thyroid.

The accompanying table shows there are not more than 39 cases on record. The first ones were those of Hickman of England in 1868; of R. Wolf of Hamburg, and Bernays of the United States. The rarity of these tumors is also confirmed by the fact that standard textbooks, such as those of Mackenzie, Cohn, Ingals and Bosworth, make no reference to them.

In 1897 Chamisso de Boncourt[3] was able to collect 15 cases of accessory thyroids at the base of the tongue.[4]

EMBRYOLOGY.

The thyroid develops from three anlages, one median and two lateral (von Kölliker, Wölfler, His and Stieda). The median anlage originates, according to Born, from the epithelium of the pharynx, while the lateral ones develop from the epithelium of the fourth branchial cleft (Fig. 1).

The median anlage develops from that part of the sulcus arcuatus which is behind and close to the tuberculum impar (Fig. 1, A). The sulcus arcuatus is the groove situated between the tissue which will become later the epiglottis, and the tuberculum impar, which will become later the tongue. The epithelium of the median anlage becomes thickened, it sinks deeper during the elongation of the neck of the embryo and becomes in this way distant from the inner surface of the pharyngeal opening, with which it is connected by a "slender, hollow pedicle" (Minot), the ductus thyreoglossus. The opening of this duct on the dorsum of the tongue corresponds to the foramen cecum (Fig. 1, B, Fig. 2, 1).

His[5] has found in embryos of from 7 to 7.5 mm. that the thyroid is composed of a small bilobed vesicle projecting a pedicle toward the surface of the tongue. In the seventh week of intrauterine life, the three anlages fuse together (Minot).

At eight weeks the thyroid gland, according to Mueller, is composed of two lateral lobes and a connecting isthmus. The glandular acini develop centrifugally, and, according to His, their development begins in the human embryo at eight weeks.

According to Mueller, at eight weeks the gland is composed of cylindrical tubes only, 0.014 mm. in diameter. Kölliker admits the existence of glandular vesicles besides.

After twelve weeks Kölliker found vesicles of 0.03-0.11 mm. The glandular cells commence to secrete between the sixth and eighth weeks of intrauterine life (Horsley). Podack, however, found developed follicles with cylindrical epithelium and colloid material much later (five-months fetus). A remarkable feature in the embryology of the thyroid is the richness in vessels in all of the embryos.

THYROGLOSSAL DUCT (FIG. 2.)

According to Butlin and Spencer,[6] the word "tract" should be substituted for that of duct, since "there is no evidence of the existence of a duct in any living animal, either during embryonic or later life."

At the end of the tract there is a depression one centimeter in depth, called foramen cecum, first described by Morgagni and afterward by Bochdalek. This is characteristic of man; it has not been found in other mammals, not even in monkeys. According to Butlin and Spencer, the dissected sinus in the Royal College of Surgeons (physiologic series, 1,526 B). may be a simple [illegible] yroglossal duct or tract connects the thyroid isthmus with the apex of the lingual V. On the level of the hyoid bone the duct is connected with the bone itself, periosteum in front, and with the thyrohyoid bursa behind. The thyroglossal duct was first studied by His in human embryos. Kanthack denied the existence of such a duct, since he could not find it in 100 adult tongues nor in 60 fetal and children's tongues. Kanthack, probably, searched for the duct at a late period, when every trace of the existence of such a duct was lost. Cysts lined by ciliated epithelium, however, tumors having the structure of a thyroid situated between the middle lobe and the foramen cecum, sustain the existence of such a duct. Embryologic remnants of the middle anlages are also found in animals, and may be displaced downward. Wölfler found in dogs, and Van Bemmelen and Meuron in embryos of sharks, batrachians and lizards, small glandular masses immediately above the arch of the aorta. They are called "aortic glands" and are embryonic remnants of the middle lobe. In man the corresponding remnants are always situated above the normal thyroid, never below. The existence of the embryonic thyroglossal tract can not be denied since a case of congenital accessory thyroid causing asphyxia is on record.

PHYSIOLOGY OF THE THYROID GLAND.

I will not go much into details concerning the physiology of the thyroid gland. Various functions have been ascribed to it, so numerous, so different, that it would require a special article to enumerate them. From clinical and experimental observations, we know to-day that the thyroid is an organ with internal secretion, its products destroying toxic metabolic substances, which normally accumulate in the blood. The ablation of the thyroid gland is followed by nervous and metabolic derangements. Astley Cooper and Rapp were the first to remove thyroids in animals. The former observed that after the extirpation of the thyroid the animal becomes sick and stupid. The latest experimenters have invariably observed that the removal of the thyroid is followed by tetany or cachexia, both equally fatal. In solitary cases where the animals remain healthy after the removal of the thyroid, von Eiselsberg assumes that, in all probability, the salivary gland was removed instead of the thyroid, or that the thyroid was only partially extirpated; or, as I believe, that accessory thyroids have taken the function of the true thyroid. Extirpation of half a thyroid is not followed by tetany. If a part of the other half is extirpated, however, tetany may occur. How much thyroid should be left in order not to compromise the function of the gland, is difficult to say. In some cases very little glandular tissue proves to be efficient; then again a large mass of gland fails to perform the function sufficiently. The glandular mass left after a partial extirpation of the thyroid is subject to ulterior macroscopic and microscopic changes. The gland left generally becomes hypertrophic.

PHYSIOLOGY OF ACCESSORY THYROIDS.

In many instances, it is presumed, the accessory thyroid supplements or takes the function of the normal thyroid. Our supposition is supported by experiments. Von Eiselsberg[7] refers to a goat which did not develop myxedema after removal of the normal thyroid. He adds that the goat had an accessory thyroid. Another goat of the same parentage, not possessing an accessory thyroid, developed pronounced myxedema after the removal of the normal thyroid. Recently, I have extirpated the thyroid of a goat, for the purpose of studying the "compensatory changes"—if any—in various organs. The tissues removed had, histologically, the structure of normal thyroid. To my great surprise, the thyreoidectomized goat is in excellent health, and has not developed myxedema. I have not acertained, as yet, whether the goat possesses accessory thyroids. In some cases, however, the presence of an accessory thyroid failed to prevent the recurrence of myxedema when the thyroid was removed.

PHYSIOLOGIC COMPENSATION.

In some instances the removal of the thyroid was followed by hypertrophy of the pituitary body. Some physiologists believe this is compensatory. Other organs, as for instance, spleen and thymus, enlarge after the removal of the thyroid, but whether there is any relationship between the ablation of the thyroid and the hypertrophy of these organs, or in other words, whether these organs make a compensatory attempt, it is difficult to say.

CLASSIFICATION.

To begin with, accessory thyroids are classified as (a) true and (b) false. True accessory or aberrant thyroids are those not connected with the tissue of the thyroid proper. False thyroids are considered those which are found within some distance of the normal thyroid but connected with the gland. Offshoots of the isthmus, the unusually long pyramid, may be considered as a false accessory thyroid. Baurowiez[8] says that the intratracheal and intralaryngeal accessory thyroids are offshoots of the normal gland.

[8] Baurowiez: Arch. f. Laryng., vol. viii, p. 2.

Several classifications have been given with very little variation. Madelung classifies them as superior, inferior, posterior, anterior, lateral, endolaryngeal and endotracheal. The hyoid is the dividing line between the superior and inferior accessory thyroids.

Streckeisen[9] classifies the tumors in the region of the hyoid bone as follows:

a. Glandulæ præhyoideæ, in front of the mylohyoid and hyoid bone.

b. Glandulæ suprahyoideæ, small nodules above the attachment of the mylohyoid muscle.

c. Glandulæ epihyoideæ, between the hyoid bone and the foramen cecum.

In this paper I will deal only with accessory thyroids between the hyoid and the foramen cecum; in other words, along the original course of the thyroglossal duct, in the middle line. The superior accessory thyroids situated to either side of that line will not be considered.

LOCATION AND TOPOGRAPHY.

The distribution of accessory thyroids is very wide. The field in which they may be found can be roughly represented by an inverted trapezoid, the larger base being a line running from one apex of the mastoid process to the other; the smaller base is a line tangential to the arch of the aorta, and the sides are the two sternomastoid muscles. Accessory thyroids have been described outside of the area above mentioned. Osler, for instance, mentions them in the pleura. They have been found in the bones, the abdominal cavity and in various organs also. Such tumors must be considered as decidedly metastatic. The occurrence of accessory thyroids is embryologically explained when they are found in the area above mentioned.

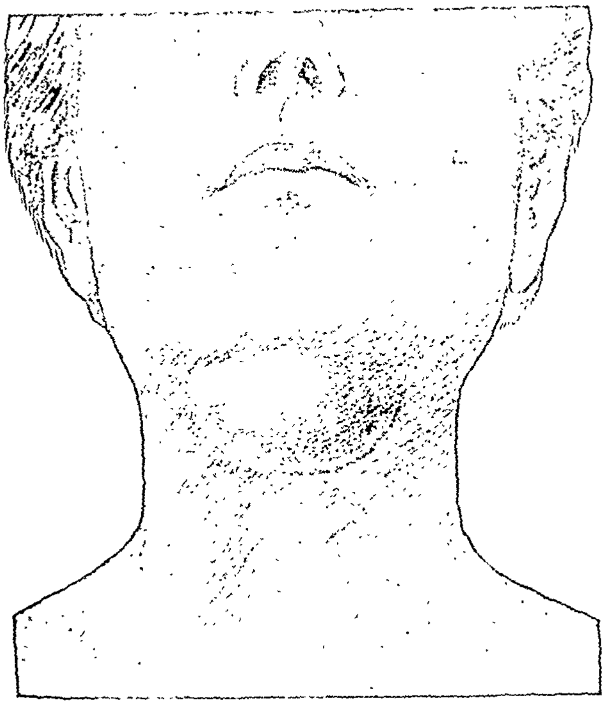

Fig. 3.—Author's case. Tumor projecting in the submental region.

Eberth[10] found small nodules in the lungs of a dog which he considered as metastases traveling along the pulmonary arteries and veins (in other words, hematogenous metastases). Neumann[11] extirpated a tumor the size of an apple situated in the region of the elbow. It had the structure of a thyroid and was considered by him to be a colloid sarcoma from the thyroid.

Tavel[12] mentions two interesting cases, one of struma metastatica of the pelvis, and the other of metastasis of the thyroid tissue in the parovarian region. Streckeisen found gland particles in the hyoid bone; according to him, the existence of these is explained by the inclusion of embryonic elements of the thyroglossal duct when the hyoid bone is cartilaginous.

K. S. De Graag[13] has referred to a case of struma with metastases in the bones. Patient had a swelling on the neck for eight years. Shortly before death he developed paraplegia. The postmortem revealed a carcinomatous tumor pressing on the spinal cord, containing follicles with colloid substance like the struma itself. It was a spinal metastasis of a malignant thyroid.

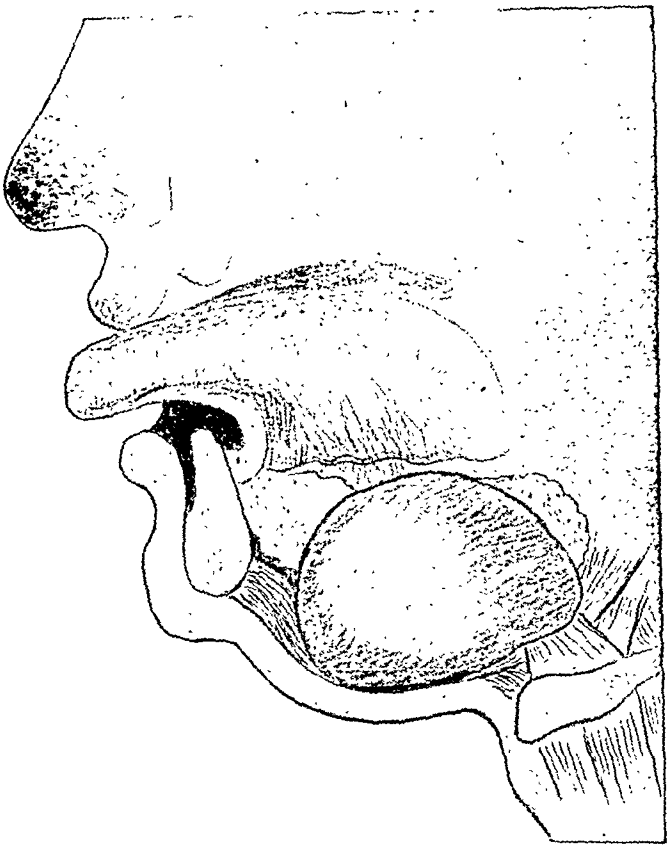

Fig. 4. Author's Case. Section, showing the position of a sublingual accessory thyroid.

I had a case[14] at Mercy Hospital of carcinoma of the thyroid with metastases in the sternum. A spontaneous fracture of the left femur occurred later, which was due to a carcinomatous metastasis from the primary carcinoma of the thyroid (Fig. 3). As I stated in the Year Book for 1903, the bones are the seats of election for secondary carcinoma of the thyroid gland, and should be suspected in all cases of malignant thyroid.

Bland-Sutton[15] refers to non-malignant metastases of the thyroid in the cranial bones.

When the malignancy of the thyroid proper can not be determined, however, we should bear in mind that simple adenomata which are considered as benign may show a malignant tendency and give metastases.

ETIOLOGY.

Age.—Accessory thyroids manifest themselves at any age. They have been found in the new-born and in the aged. Hickman's case was a child 2 days old; while in the case of Staelin the tumor was found at a postmortem in a woman of 77. According to Onodi, they develop most frequently between 12 and 35 years of age.

Sex.—All writers have observed that these tumors occur mostly in women. The relationship between changes in the female genitalia and the thyroid has been noted (as illustrated in the frequent hyperplasias and degenerations of the thyroid at puberty, immediately following parturition, abortion and pathologic menopause). In the case of Shadle, during suppression of menstruation the accessory thyroid became more swollen and more vascular. We have no palpable explanation for this relationship, but venture to say the development of the accessory thyroid has something to do with the abnormalities of menstruation.

Occurrence.—Accessory thyroids have often been found in postmortems, and particularly in the morgues of countries where goiter is common. Pathologists have mentioned the occurrence of such tumors in the Tyrol. Streckeisen found many accessory thyroids in the pathologic institute at Basle.

Exciting Causes.—In most of the cases there is no palpable cause for the rapid development of the accessory thyroid. In a few cases, however, acute infectious diseases may be considered as an exciting cause. In Warren's patient grippe was considered its excitant; in Wolf's patient, whooping cough, and in several instances puberty was closely related to the development of these tumors.

PATHOLOGIC ANATOMY.

As we stated before, only the tumors situated along the thyroglossal tract will be considered. They are generally found at the base of the tongue, either elevating the organ by their size, or penetrating the muscles and forming an elevation on the dorsum. The size varies from a cherry to an egg, and may even attain that of a fist. The tumor is well encapsulated and is not surrounded by any inflammatory area; the color is a bluish red, which is due to the abundance of vessels. The surface is covered with a smooth, shining mucous membrane, the normal mucosa of the tongue. It is traversed by many vessels, not only on the surface, but even penetrating the tumor. The consistency is soft, and it is often difficult to decide whether one has to deal with a soft tumor or a cyst. Tumors at the base of the tongue are generally single; in Bernays' case, however, the tumor on the dorsum of the tongue was accompanied by another one immediately above the hyoid bone. The tumor may be movable if it is small, or immovable if it attains a great size. It is usually smooth, but it may be made irregular by the existence of small cysts. The contents of the cysts are generally colloid material; if the cyst is large and the vascularization great, the contents may be bloody.

As to the origin of these tumors, according to Butlin and Spencer, there are two theories:

a. They originate from the follicular glands situated on the dorsum of the tongue, or, it would be better to say, from the glands behind the circumvallate papillæ.

b. They are remnants of the thyroglossal tract.

The first theory was originated and is sustained only by Bowlby. I question the theory, as it would require a transmutation of cells both anatomic and physiologic. Such metamorphosis from squamous to columnar epithelium is very rare, even if at all possible. The second theory is supported by Bernays and Bland-Sutton, and by most of the writers who have described such tumors. This explanation is analogous to those referring to many other embryonic remnants.

Butlin considered these tumors at the beginning as *simple edenomata, but finally admitted that they were* products of embryonic thyroid remnants, and therefore true thyroids.

Some tumors show the structure of a normal thyroid, spaces lined by cubical epithelium and containing some colloid material. Some show the structure of a goiter, some contain embryonic tubules. In Kraske's case, the tubules contained a great many embryonic thyroid cells; in other cases we find cystic conditions.

The accessory thyroid may be encountered where a thyroid exists in the normal location. In several instances, however, the accessory thyroid was the only thyroid found. The accessory gland may undergo cystic degeneration and form large cysts extending from the hyoid bone to the foramen cecum, or it may become malignant; or be, to all appearance, benign and still malignant in its tendency, as is proved by its recurrence after removal and the production of metastases. We know, from Cohnheim, that adenoma gelatinosum of the thyroid, which is benign, may give metastasis.[16] It is also known that enchondromata and myxomata, which are generally benign, may run a malignant course. In 1883 Bryant described a cyst at the base of the tongue reaching the circumvallate papillæ of five months' standing in a girl of 18. It was lined with ciliated epithelium. Johnson describes a congenital cyst situated between the circumvallate papillæ and epiglottis, and lined by several layers of flattened epithelium. In young adults, regardless of sex, cysts situated below the mylohyoid may be found; they are small at first, but may reach the size of a mandarin orange (Liaras). As Durham showed in his researches, these cysts are also lined with ciliated epithelium and arise secondarily in thyroid tumors.

PERSONAL CASES.

Case 1.—Mrs. M. M., aged 34, admitted to Mercy Hospital April 12, 1905; operated on April 13.

Family History.—One grandmother had epithelioma of the lip. The other grandmother had carcinoma of the breast.

Personal History.—Patient menstruated at 15; it was regular, not painful; no intermenstrual discharge; the amount of menstrual fluid was usually large. Married at 25. Gave birth to five children under normal conditions; no abortions.

Previous Illnesses.—Negative.

Present Illness.—Fifteen years ago patient had a tumor at the base of the tongue. She was admitted at the time to the Presbyterian Hospital, Chicago. The condition was not diagnosed, but an attempt was made to operate on the tumor through the mouth. So profuse was the hemorrhage that the surgeon had to discontinue the operation. Following that attempt the patient improved, though the tumor did not disappear. She says of the accident during the operation, "I nearly bled to death." Five days after the operation the patient had a second hemorrhage. In the course of time the tumor did not cause very much inconvenience, with the exception of some mechanical irritation. Patient even states that the tumor reduced somewhat in size in the first six years after the surgical attempt. Nine years ago patient noticed below the old tumor a new one protruding in the submental region a little to the left of the median line (Fig. 3). No serious derangement was noticed. The tumor increased greatly in size until it reached its present dimensions, about those of a hen's egg (Fig. 4). No disturbances of mastication, deglutition or respiration were noticed by patient. General health very good; appetite fair. No gastrointestinal or genitourinary symptoms. No loss of weight or strength in the last fifteen years.

---

[16] Virchow's Arch., vol. lxviii.

Operation.—The tumor was exposed by a longitudinal incision through the muscles, starting from the symphysis menti and extending down to the hyoid bone. The geniohyoid muscles were separated by retractors (Fig. 5). The tumor could be circumscribed by the finger and was enucleated without difficulty. There was no hemorrhage. The wound was closed in the usual way. The day following the operation, patient's temperature reached 101 degrees. On the sixth day there was primary union of the wound. On the ninth day there was some retention of serum and blood under the skin which necessitated a separation of the edges of the wound to allow their escape. No drain was inserted. The patient was discharged cured, April 22.

Case 2.—Mr. C. H., aged 45, farmer, was admitted to Mercy Hospital Jan. 30, 1901.

Family History.—Negative.

Personal History.—Patient was born in Germany and came to the United States when a boy. A man of good habits. Married at 18; had six children, all living and in perfect health.

Previous Illnesses.—In September, 1900, patient was kicked in the hypogastrium. The accident was followed by hematemesis and distension of the abdomen; elevation of temperature. Gradually recovered and was able to resume his work as before.

Present Illness.—Three weeks ago, while looking in his mouth through the mirror, he noticed a swelling at the base of the tongue and slightly to the left. From this time up to his entrance to the hospital, the patient did not have any pain nor discomfort. He had no difficulty of mastication, deglutition or respiration. Was operated on January 31.

The microscopic sections showed large glandular lumina filled with colloid material (Fig. 7).

SYMPTOMS, DIAGNOSIS, DIFFERENTIAL DIAGNOSIS.

The diagnosis of the accessory thyroid is very difficult. At first there are practically no symptoms; possibly the patient may have noticed the growth for some time, but may not have suffered any inconvenience from it. As soon as the tumor begins to enlarge, the patient complains of "lump in the throat." There is some difficulty in deglutition; salivation may be increased; some patients have a reflex dry cough not accompanied by expectoration. Most patients notice a change in the pitch of the voice; the voice may be either impaired or entirely changed. When the tumor attains a certain size patients complain of dyspnea, and if the epiglottis is pressed down, symptoms of suffocation may follow. Some patients notice from time to time an iron taste, due to the insignificant oozing of the tumor, or, in case of the rupture of a vessel, the patient may have from a moderate to a very severe hemorrhage. The absence of pulmonary physical signs, cough, expectoration and bacilli or that of gastric symptoms excludes hemoptysis or hematemesis. [illegible] are no constitutianl symptoms; anemia, however, may be present in those cases where oozing or hemorrhage has been present for some time. In Schadle's case there was a marked wasting and nervous exhaustion. The discovery of the tumor is generally a source of great mental anxiety to the patient. Many are of the opinion it must be a "cancer," and that an operation will involve the tongue.

Generally speaking, whenever a diagnosis of the true nature of a tumor of the neck is not well established, an accessory thyroid should be suspected (Hinterstoisser).[17] If a tumor is found at the base of the tongue or between the hyoid and the base of the tongue, in or near the middle line, if there is no inflammatory reaction around the tumor, if there are no marked subjective symptoms, and if it undergoes periodic variations in size and tension, if the patient be a woman, and especially one who complains of some disturbance of menstruation, the condition is highly suggestive of an accessory thyroid. The diagnosis may be greatly facilitated if, with the presence of such a tumor, we fail to find the thyroid in its normal location. The accessory thyroids are probably more frequent than is believed, judging from the number of recorded cases. They are generally not diagnosed until they become large, strumous, or until they cause alarming symptoms. I think it would be a good practice to administer in each case of suspected accessory thyroid, thyroid tablets. If it then diminishes in size, one could be certain that one's diagnosis was correct. Some surgeons have punctured or attempted to aspirate the contents, which appeared to them to be cysts. Such attempts have been very discouraging, since puncture is often followed by profuse hemorrhage. No fatalities have resulted; nevertheless, I believe such a procedure must be considered both useless and dangerous.

DIFFERENTIAL DIAGNOSIS.

After a tumor has been diagnosed at the base of the tongue, either by inspection, palpation or the use of the laryngoscope, if the tumor protrudes on the dorsum of the tongue, the first thought which occurs to the surgeon is whether it is malignant or benign. The absence of ulceration, the fact that the tumor is well circumscribed, even encapsuled, the absence of glandular enlargement, of constitutional symptoms, of pain, the long-standing of the tumor, the fluctuation in size, and the general youth of the patient, undoubtedly dispel the suspicion of a malignant tumor.

The conditions which have to be considered in making a differential diagnosis are as follows:

1. *Cysts.*—Above the hyoid bone in the middle line, cysts are found that are not embryologic remnants of the thyroglossal tract. They may be due to an inclusion of epithelium, which develop suddenly after a local irritation. These are cysts due to remnants of branchial clefts, retention cysts of excretory glands, dermoid cysts.

2. *Ranulæ.*—A ranula is due to a retention in the duct of the sublingual or submaxillary gland. The tumor appears on the floor of the mouth and pushes the tongue to one side. It has a thin wall and its contents are semi-translucent. The tumor may be covered by abundant and large veins, in which case the differential diagnosis from an accessory thyroid is difficult. The subjective symptoms are in many respects similar to those of accessory thyroids.

3. *Polyps.*—These are due to a hyperplasia of the lymphatic tissue at the base of the tongue, syphilis and tuberculosis being generally the etiologic factors. Children with hypertrophic tonsils frequently have these lymphatic masses under the tongue. The enlargement of the lingual tonsil may form a tumor to the side of and behind the tongue. "Lyssa" (hypertrophy of the tonsils of the palate) may simulate an accessory thyroid by its location.

4. *Papillomata.*—These are rare. They are divided by Albert into flat and pedunculated.

5. *Angiomata.*—These are frequently found at the base of the tongue. They have the same aspect as the accessory thyroids and may present the same clinical feature, that is, oozing or hemorrhage. The color of the angioma, however, is of a deep blue, almost black, and it empties by pressure.

6. *Lipomata.*—This form of tumor is very rare at the base of the tongue. The lemon-yellow color is highly suggestive of this tumor. A puncture would not cause bleeding; there is absence of oozing or hemorrhage.

7. *Fibromata.*—Fibromata in this location are rare. They may be pure or mixed. According to Fisher, they are submucous and are either single, double or triple. They reach the size of a pigeon's egg, have a pale color, and seldom bleed. There are on record two cases of fibroma of the tongue, one described by Pooley and the other by Fith. The first case was that of a girl. The tumor caused symptoms of suffocation and hemorrhage, both of which are met with in accessory thyroids; the differential diagnosis was therefore impossible.

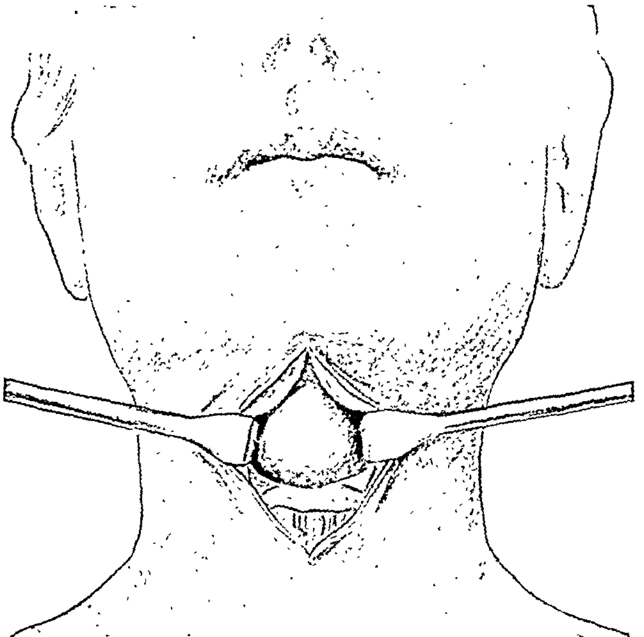

Fig. 5. Author's case. Tumor exposed by a submental vertical incision.

Gibb described a fibroid tumor the size of a billiard ball a little to the left of the base of the tongue. In the museum of the Royal College of Surgeons there is a specimen of a fibroid tumor the size of a walnut, situated at the base of the tongue.

8. *Syphilitic Gumma.*—In the absence of a history of syphilis, one should be able to find some syphilitic stigmata. The gumma usually has a tendency to ulcerate; it is not vascular. Anti-syphilitic treatment would be of great value, since tertiary affections are frequently benefited by specific treatment.

9. *Tumors of the Larynx.*—These first give disturbance of speech and generally distinct symptoms of asphyxia, and should be carefully differentiated.

In the differential diagnosis I desire to call attention particularly to the clinical course, the duration of the growth and the presence or absence of the normal thyroid.

TREATMENT.

The treatment is both medical and surgical. Medicinal treatment is generally unsatisfactory. Iodid of potassium occasionally slightly diminishes the size of the tumor. Local application of astringents may also reduce the size somewhat. External counterirritants have been applied, although without any satisfactory results. I suggest the use of thyroid tablets, which have proved to be of benefit in both exophthalmic and simple hypertrophic goiter. Before resort to surgical treatment it is an absolute duty to ascertain whether or not the patient possesses a thyroid in the normal location. As the accompanying table shows, grave mistakes have been made by surgeons who did not ascertain before the operation the presence or absence of the thyroid. That point is perhaps the most important one of this entire paper. The accessory thyroid may be the only one that the patient has, and of course all know what the natural result would be if such a precious organ were removed. Out of 39 cases recorded, 5 cases have developed myxedema within a longer or shorter time after the operation. If one is able to ascertain that the thyroid is present, and if such tumors cause a great deal of inconvenience or discomfort to the patient, surgical treatment is not only admissible but

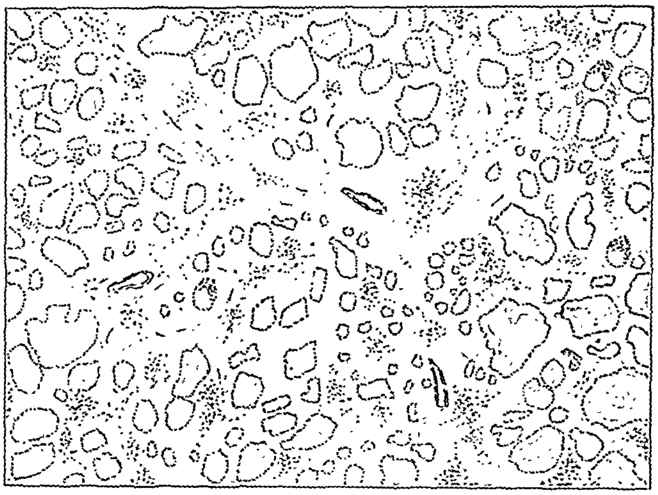

Fig. 6.—Section of a normal thyroid.

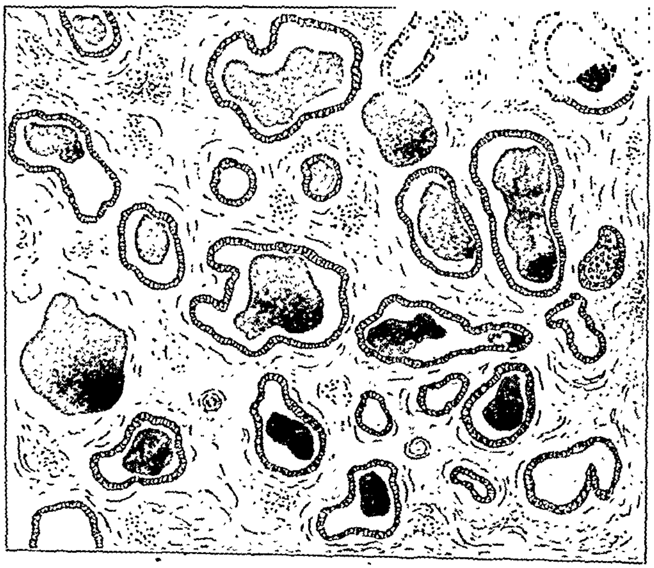

Fig. 7.—The section shows large glandular lumina, filled with colloid material. There is some hyperplasia of the connective tissue.

advisable. On the other hand, it must be borne in mind that the thyroid may be present, but on account of some pathologic condition of the organ the accessory thyroid begins to enlarge, which is frequently a physiologic compensation, and in these cases the removal of an accessory thyroid, regardless of the absence of the normal thyroid, is justified only when the tumor is sufficiently large to press down the epiglottis and cause symptoms of asphyxia. Even in such cases the surgeon should be conservative; that is, he should endeavor to remove only a part of the accessory thyroid.

SURGICAL TREATMENT.

Surgeons, assuming that they have to deal with a cyst, insert the trocar or aspirating needle; the former may become dangerous if used as a means of treatment; the latter is harmless for diagnostic purposes and useless as a means of treatment. Tincture of iodin, chlorid of zinc and other drugs have been injected in the tumor, but without good results, and the injections are not free from danger. The sublingual tumor can be extirpated either through the mouth or through a submental incision. In some cases, especially where the tumor is small and immediately under the mucosa of the tongue, it can be advantageously extirpated through the mouth. There is seldom any difficulty in enucleation; it can be accomplished with the scalpel or by blunt dissection. The hemorrhage that accompanies such a tumor may be alarming in aspect, but it can be controlled. General anesthesia is usually employed; cocain, however, has been used. If general anesthesia is employed, the mouth should be gagged, the head low and the tongue forcibly drawn forward. In several instances tracheotomy was resorted to in performing this operation.

SUPRAHYOIDAL OR SUBMENTAL ROUTE.

This is the route of election in all cases, and particularly if the tumor is large and protrudes beneath the chin. An incision is made from the symphysis menti down to the hyoid bone. The corresponding muscles are separated by retractors, and as soon as the tumor appears in the incision there is no difficulty of enucleating it either by the knife or the galvano-cautery. The presence of the thyroid in the normal position should be determined in every case before removing the sublingual growth, even though it necessitates a dissection of the neck.

RESULTS.

The prognosis is generally good if the normal thyroid is present. There is no death recorded after this operation.

Recurrence of the tumor has been noticed in 6 out of 39 cases. The most unpleasant experience recorded after extirpation of such tumors is the occurrnce of myxedema; this occurred five times in the 39 cases, as seen in the tables.

In closing, I wish to express my appreciation to Dr. Victor L. Schrager for collecting the literature of this subject.

Why a Country Doctor Should Dispense His Own Drugs.—You are certain to furnish a reliable article. You are certain that no "just as good" plays at cross purposes with you. You are certain that your formulas stay your own property. You get rid of refilling prescriptions without authority. You keep the privacy of your patient between yourself and him. You pocket a better fee, and your patient is better satisfied.—*Central States Medical Magazine.*

THE ALBUMOSURIA OF PHTHISIS.

A CLINICAL STUDY.*

J. F. M'CONNELL, M.D.
COLORADO SPRINGS, COLO.

Some two years ago, while working up a series of urinalyses for the purpose of computing the prognostic value of Ehrlich's reaction in the tuberculous, my attention was directed to a large proportion of the specimens having a precipitate with the characteristics of an albumose. There was very little to be found in the literature concerning the significance of this adventitious content; to be more precise, many authorities denied that it portended anything. Hence, the investigation and conclusions here presented I believe to be original.

Albumosuria may be defined as the presence in the urine of a primary product of the digestion of a proteid, differing from albumin in not being coagulable by heat. The albumoses appearing in the urine have a wide nomenclature, which is of little clinical interest. Suffice it to state that it has been conclusively shown that such products are in no wise to be considered as peptones (in the sense of Kühne), which never appear in urine. The physiologists tell us that these bodies are excreted by the renal function when the intracellular disassimilation of proteids is perverted. With this and other theoretical observations I have little to do, as my purpose is to present a clinical deduction, which, if confirmed, should be of vast benefit, namely, the placing of the empiric therapeutic idea of rest on a rational basis.

The twenty-five cases studied during the first six months were patients presenting the ordinary evidences of tubercular invasion who were seeking amelioration through climato-therapy. In their symptoms they were fairly similar. The majority suffered from febrile disturbances, which varied only in degree. All such were subjected to the empirical idea of rest, and it was noticeable in these cases, as in many others preceding them, that some patients did not improve under rest, but did become better when allowed to exercise, such improvement being attributed to better elimination of the toxic products of the disease. But why? Fever denotes a dissolution of the body substances and increased absorption of fat and albumin. Exercise intensifies this; the reparative functions being below par, there is a continued absorption, not only of the tissues of the body, but of the proteins, the etiologic factors of more fever, and yet the experience above given is a common one.

Systematic urinalyses were undertaken and the following observations recorded. With a view to conciseness, these may be reviewed from a triple standpoint: First, those febrile patients giving a positive reaction whom I have designated albumosurics; second, febrile patients giving a negative reaction under rest and exercise designated non-albumosurics; third, non-febrile subjects giving a negative reaction despite the fact that overexertion, mental stress, hot baths, etc., cause a rise in temperature.

Observation 1.—A. B. C., male, aged 26, weight 145 pounds, normal weight 164 pounds, good family history, clinical and bacteriologic evidences of tubercular invasion of right superior lobe; morning temperature, 97 3/5° Fahrenheit; pulse, 80; slight chilliness at 11 a. m., afternoon rise varying from 101 3/5 to 102° Fahrenheit; pulse, 90 to 96; gradual loss of weight. Urinalysis, positive reaction to albumoses test.

---

* Read before the Colorado State Medical Society at its Annual Meeting, held in Colorado Springs, 1905.

Patient placed at rest on sleeping-out porch. Chill anticipated and usual disciplinary methods enforced. Temperature gradually declined to almost imperceptible afternoon rise. Albumoses disappeared some days later. Gain in weight. Patient allowed limited exercise without bad effect. After a week patient overstepped bounds, fever and albumosuria returned, with loss of weight as a resultant.

Observation 2.—J. K. L. is representative of the second class. Male, aged 22, weight 151, clinical and microscopic evidences of tubercular involvement of both apices; morning temperature, 98; pulse, 82; afternoon rise of 100 to 100 3/5; pulse, 88, which was persistent, though disciplinary rest treatment was enforced. Albumoses were at no time demonstrable in the urine.

During rest patient lost eight pounds in weight. Exercise, under supervision, was then permitted with the happiest results. At present time patient is playing golf each day, has gained fifteen pounds in weight, temperature is normal and pulse nearly so.

Observation 3.—X. Y. Z. is cited as a representative of class three. Male, aged 28, at one time tubercular fibrosed right apex. After fatiguing exercise, mental excitement, etc., there is an afternoon rise to 100. Test for albumoses negative.

In the 129 records at my disposal, of which the above serve as types, there is much of interest to be gleaned as to classification, but this I leave for more mature investigation. Briefly stated, it is evident that the albumosuric patients suffered from a rise of temperature, increased by exercise, which was febrile in character—contrariwise non-albumosurics presented a rise of temperature—which was not benefited by rest and in whom exercise under supervision was attended by the happiest results.

TESTS.

In all cases of albumosuria the amount of albumose that appears in the urine is relatively small, and as a rule can not be demonstrated by the biuret test when applied directly to the native urine; on the contrary, it is necessary to isolate the substances more or less definitely before deductions can be drawn as to its presence or absence.

Test.—Ten c.c. of urine are treated with 2 c.c. of a saturated salt solution in order to get rid of the common albumins, acidified with 5 drops of dilute acetic acid boiled and filtered while hot; coagulated albumins remain behind while albumoses go into the filtrate from which they separate on cooling. The filtrate should then give the biuret reaction, which is best brought about in the following manner:

The urine is heated with potassium or sodium hydrate solution and a 10 per cent. copper sulphate solution added, drop by drop. The positive reaction is a rose coloration.

If in a suspected specimen the reaction with the above test should become negative, it is often worth while to try the following method: 10 c.c. of urine are treated with 8 grammes of ammonium sulphate; the fluid is then boiled for a moment, placed in the centrifuge for one minute, and the sediment stirred with alcohol in an agate mortar. The alcohol is then poured off and the residue dissolved in a little water. This solution is boiled and filtered and the filtrate tested for the biuret reaction. By this method it is possible to demonstrate albumoses in a dilution of 1/5000.

708 North Tejon Street.

Thoroughness.—It is not good to be a bigot, and to give no credit for intelligence to our opponents, either in politics or in religion; but there is something worse than bigotry, and that is instability—to have no opinion except what is pumped into you by your neighbor, or to have one opinion to-day and another to-morrow, or never to rise above opinion, and to reach conviction. This . . . indecision may be due to a certain quality of mind which never can come to a conclusion, and never can take a side strongly, but the chances are that want of conviction means intellectual indolence. . . . Let us believe something with all our might, for the day will come when God will give to the honest thinker more light.—Ian Maclaren.

THE ROENTGEN RAYS IN DENTISTRY.*

MIHRAN K. KASSABIAN, M.D.

Director of the Roentgen Ray Laboratory of the Philadelphia Hospital.

PHILADELPHIA.

The discovery of the Roentgen rays in 1895 marked a new epoch in the domain of dental surgery. The first skiagraph of the teeth was presented to the Society of Physics of Frankfurt-on-the-Main, in February, 1896, by Prof. Koenig. In April, 1896, at the Congress of Erlangen, Walkhoff demonstrated many skiagraphs of the teeth in the living subject. Dr. W. J. Morton wrote an article which appeared in the *Dental Cosmos,* June 1896, on "The X-rays and Their Application in Dentistry."

Since then, many dentists and physicians in this country and abroad have endeavored to bring dental skiagraphy to a greater degree of perfection; yet the field is wide and requires many modifications and improvements.

TECHNIC.

Although the technic and principles of dental skiagraphy do not differ greatly from ordinary skiagraphy, I wish to describe it very briefly for the benefit of those who are interested, and are desirous of entering on this special subject.

The apparatus that I have recommended for the production of the *x*-rays is a small Ruhmkorff coil, 6-9 inch spark producing size, energized by a storage battery, or a 110 volt, placed on a shelf, etc. The Crookes tube should have such a vacuum so as to produce rays of good penetration. The direction of the rays in relation to the teeth and jaw is most important; the position of the tube and part must be so arranged as to skiagraph the part without superimposition of the different structures.

TECHNIC OF DENTAL SKIAGRAPHY.

Fluoroscopic examinations in dental work do not yield satisfactory results. The two methods of skiagraphing dental conditions at present most commonly employed are: A. The intraoral. B. The extraoral or buccal.

A. The Intraoral Method.—This consists in inserting a small piece of film (light and moisture proof) over the gum tissue where trouble is suspected, and in placing the tube in such a position that the rays will fall perpendicularly on the teeth and film. A small sensitive plate, being inflexible, cannot be made to adapt itself to the curvature of the part.

Price, of Cleveland, encloses the sensitive film in unvulcanized black dental rubber, using a sheet of sensitive bromid paper to protect the emulsion. Rollin, of Boston, encases the film in an aluminum cover. Ordinary kodak films can not be used for this purpose.

Personally, I prefer a specially prepared thick, double coated film. I cut it to the size required for the special condition, and enclose it in a layer of black paper, after which the paper is so folded as snugly to enclose the film; the whole is placed in a yellow envelope just large enough to accommodate the size of the paper and film; the smooth side corresponds to the sensitive side of the film.

Place the patient preferably in the dental chair and adjust the tube. In the latter procedure, see that rays fall perpendicularly to the vertical apex of the teeth. If the adjustment of the tube be faulty the shadows of the teeth will be distorted.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

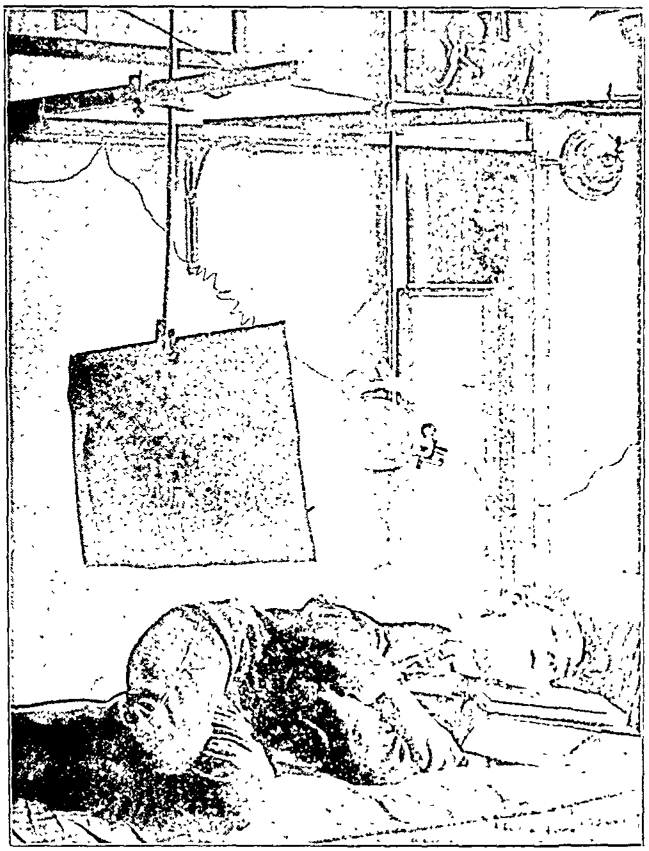

Fig. 1.—The extra-oral or buccal method, showing the positions of the patient and tube and the lead screen to protect the operator.

Care should be taken to place the film against the hard palate in order to include in the skiagraph the roots of the teeth. Before its introduction into the mouth, the enveloped film should be reinforced by two rubber bands. It must always be remembered that a skiagraph of the superior maxillary bone is less satisfactory than of the inferior maxillary, as the film cannot be placed in a line parallel with the teeth. Two films (superimposed) can be taken at one exposure.

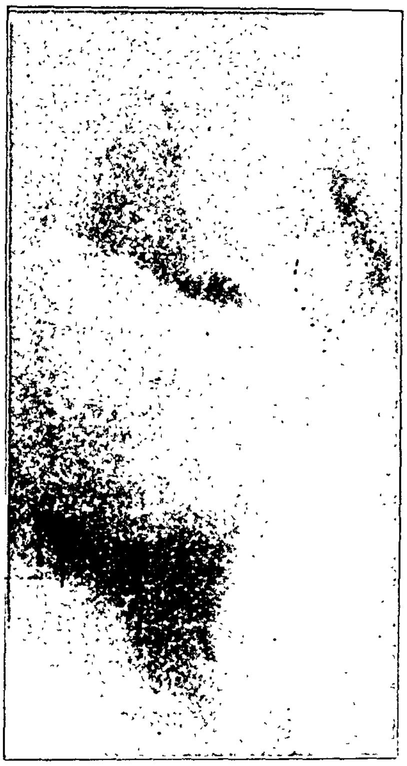

Fig. 2.—Unerupted upper right cuspid (Dr. Dray's case).

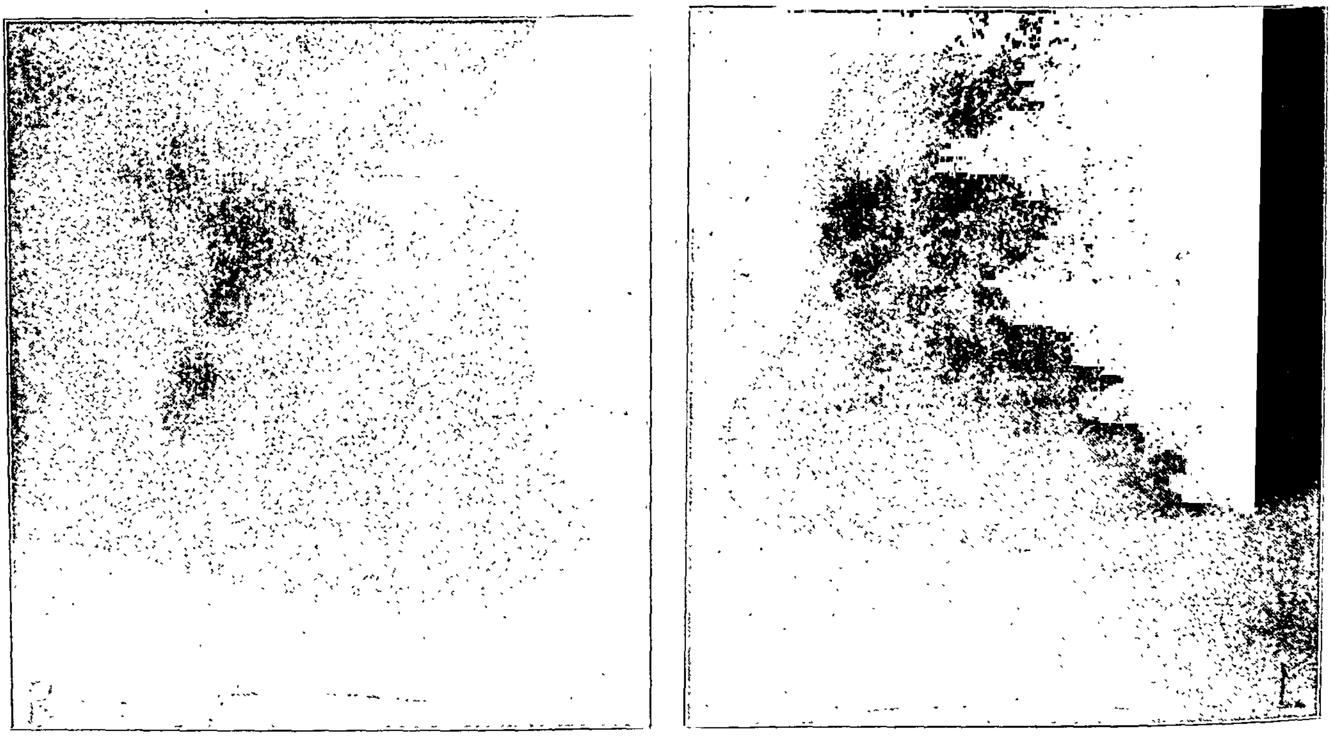

Fig. 4.—Unerupted right and left second bicuspid of lower jaw (Drs. Cryer and Smith of Baltimore).

As only one or two teeth can be taken at one time, the film should be pressed against the affected part; the exposure varying from two to ten seconds. The advantage of this method is to be found in the sharper definitions on the negative, but it must be remembered that only a small area can be taken.

B. The Extraoral or Buccal Method.—This requires a plate 8x10 against the jaw at the suspected region.

A block of wood is wedged between the widely extended jaws, and the patient is directed to lie on the affected side and to incline the head and neck to an angle of about 45°. The tube is now placed over the opposite shoulder, the latter being protected by a sheet of lead (the tube being placed very close to the shoulder). The rays are sent obliquely at a distance of 20 inches from the face to avoid overlapping of the shadows of the jaws. The method produces a picture of greater area, and is intended for bicuspids and molars of both jaws. Exposure varies from one to three minutes (Fig. 1).

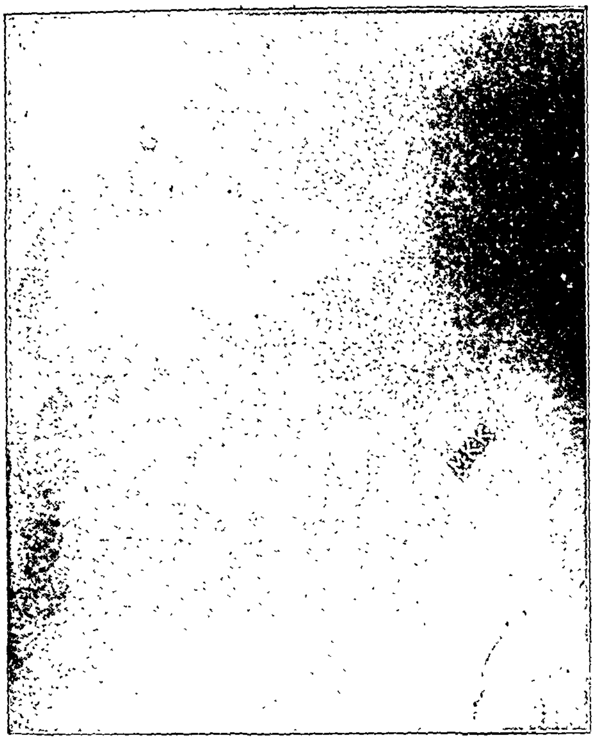

Fig. 3.—Unerupted upper left cuspid (Dr. M. H. Cryer's case).

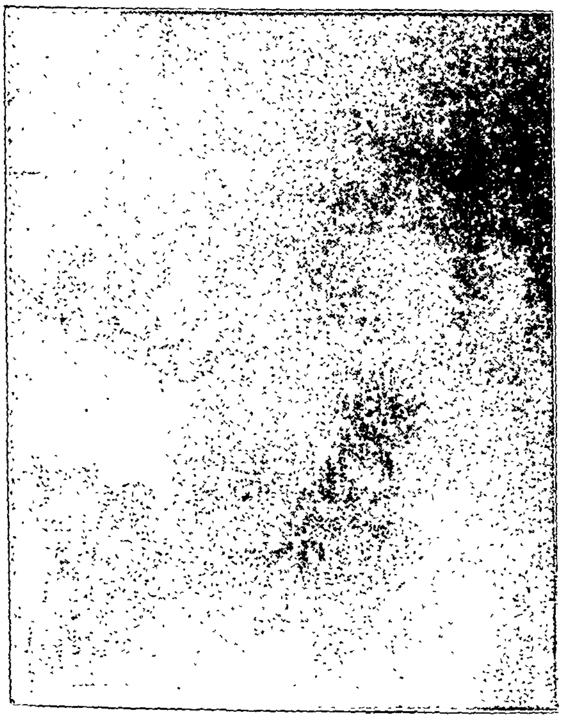

Fig. 6.—Pericemental and alveolar necrosis of the upper third molar on which was bridgework (Dr. W. Freeman's case).

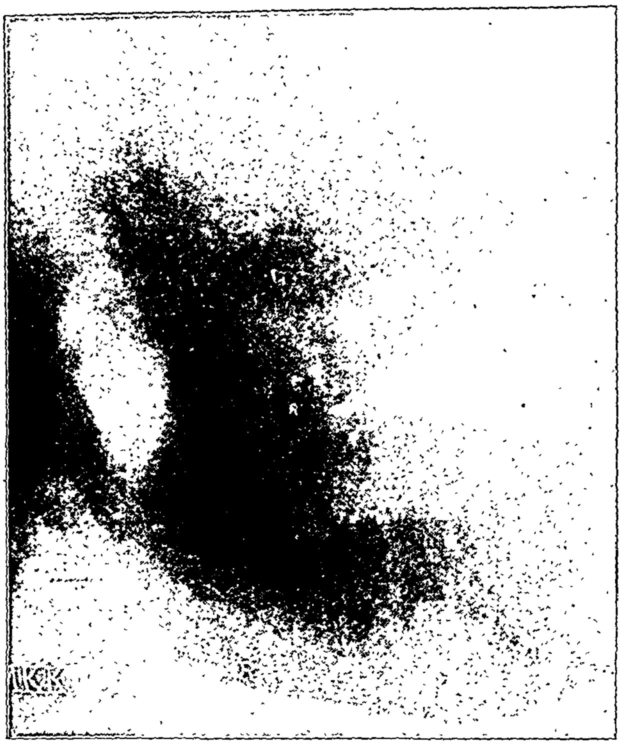

Fig. 5.—Unerupted third molars on both sides of lower jaw and one on the upper right side (Dr. M. H. Cryer's case).

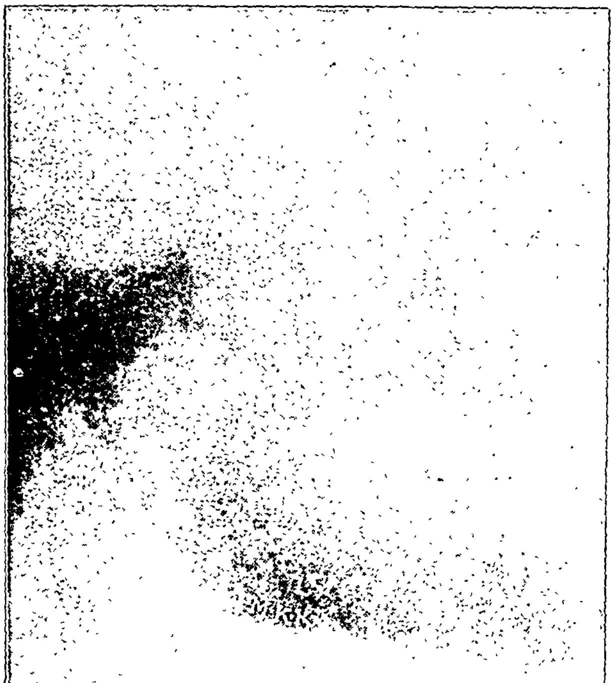

Fig. 7.—Dr. Jaco's case. Broken root of the right upper canine.

THE CLINICAL APPLICATION.

This method will assist in studying the anatomy and physiology of the oral cavity, viz., the eruption and evolution of the teeth.

Anatomy.—The sinuses, dental canals and foramina, antrum of Highmore and many other conditions in normal or diseased states, can be studied most thoroughly.

The structures of the teeth can be studied; namely, enamel and dentine give different shadows, the former being a denser shadow than the latter. The pulp, dental canals, etc., are likewise visible.

Evolution of the Teeth.—The evolution can be studied from the second month of the embryonic life, and each month thereafter. Calcification, which begins at the crown of the tooth, can be studied in its different stages.

Unerupted and Retained Teeth.—An important condition coming under the dentist's care is the retention or non-eruption of a permanent tooth owing to the temporary tooth remaining in the alveolar socket beyond the age considered normal. If the skiagram reveals the unerupted tooth to be of normal shape, and so located as to permit of its eruption, the indication is to remove the temporary tooth.

Cases of odontalgia frequently reported are undoubtedly due to an unerupted tooth; in such cases the etiologic factor may be revealed by the *x*-rays.

The following are a few of the cases in which *x*-rays were utilized for this condition.

Case 1.—Unerupted upper cuspid of the jaw; referred to me by Dr. Dray in 1900; patient a medical student complaining of facial neuralgia, etc. (Fig. 2.)

Case 2.—Unerupted cuspid of upper jaw referred to me by Dr. Cryer. Patient had a swelling under the eye; he suffered pain; had eye symptoms, headache, etc. (Fig. 3.)

Case 3.—Unerupted second bicuspid of the inferior maxillary bone in a girl of 12, on the right and left side, referred to me by Drs. Cryer and Smith of Baltimore. (Fig. 4.)

Case 4.—Unerupted third molars on both sides of lower jaw, and one on the upper right side, referred to me by Dr. M. H. Cryer. (Fig. 5.)

Foreign bodies and broken instruments, defective root fillings, whether properly and completely filled or not. Fracture, etc., and metal splints can be studied.

Ankylosis of the inferior maxillary articulation, tempero-maxillary, whether it is bony or false, can be studied both fluoroscopically and skiagraphically. This ankylosis may be true or false, partial or complete, depending on the cause; both fluoroscopic and skiagraphic examination is necessary. The extraoral or buccal method should be employed. In early stages, the articular and cartilaginous joint presents an irregular surface, and in time ankylosis occurs, as when following a fracture involving the joint. The latter may be seen to be wholly obliterated, absence of movement being manifested clinically in false ankylosis. The joint is seen to be eroded, the fibrous adhesions not showing unless they have become partially infiltrated with inorganic salts. False ankylosis is often due to rheumatism or to syphilitic diathesis.

Dead pulp in a tooth is indicated by a break in the continuity of the pericemental membrane at the apex of the root, by more or less absorption of the adjacent osseous tissue, and occasionally of the roots in long standing cases. In the majority of instances, such an abscess is due to imperfect treatment, but in many cases the canal of the root is so narrow and irregular as to make it almost impossible to fill the canal or cavity to the apex.

When a case presents symptoms of a pericemental inflammation, and the history is uncertain, the most rational procedure is first to skiagraph the field, thus ascertaining the exact location and extent of the lesions, and often its cause.

Case 5.—Dr. P., patient of Dr. W. Freeman, suffered intense neuralgia, with painful reflexes from the ear, nose and eye. He had a bridge on the third upper molar. The skiagraph showed a pericemental and alveolar necrosis; tooth was removed and alveolar process was cleaned, etc. (Fig. 6.)

Case 6.—This was a patient of Dr. Cryer. The angle of the inferior maxillary bone was swollen and painful. A skiagram was taken while the probe was inserted. It showed a necrotic condition of the angle of the lower jaw, and the probe was inserted up in the canal. There was found an unsuspected necrosis. The patient was operated on and several months after the skingram showed the regeneration of the bone.

Case 7.—Dr. Gaylord's case, Mr. E., aged 65.

History.—Three years ago the third molar was removed, and an artificial plate was made. Three months after swelling around the first cuspid was noticed.

Treatment and Result.—On account of his age, the surgeons thought it malignant, and so operated and curetted the (abscess) bone, as shown in the skiagram.

After the operation (three years ago), there was a sinus, which gave him much discomfort and pain; every remedy and surgical treatment proved unavailing. A skiagram showed a broken root on the plate, and on the film it showed the root was 2 mm. under the gum tissue. The root could not be felt. Dr. Gaylord removed it, and with an injecting solution showed the sinus to communicate with the root of the tooth. The patient recovered in four weeks.

Case 8.—A woman, aged 65, was referred to me by Dr. Jaco. The patient had suffered for fifteen years from neuralgia of the right side of the face. Dr. W. W. Keen removed the infraorbital and infradental nerve, but the neuralgic pain still persisted. A skiagraph revealed a small broken root of the right upper canine tooth. Prior to a careful study of the case thirteen sound teeth were uselessly extracted. Before making plates for artificial teeth, the dentist referred the case to me, to inquire if the rays would discover a retained root, which would cause a repetition of the former trouble. (Fig. 7.)

ABSCESS OF ANTRUM OF HIGHMORE AND FRONTAL SINUS.

A skiagram of a lateral view of the face and suspected side next to the plate will always show an abscess of the antrum, but the better way, and I always prefer it, is to have a skiagram of the occipito-frontal view, viz., the patient puts his head over the large plate and rays come from the occiput. This view will show the affected side, which can be compared with the normal side. Frontal sinuses can be shown by lateral view.

Recently I examined a retired physician, the case being referred to me by Dr. J. Solis-Cohen. A skiagram showed pus in the frontal sinus; two skiagrams were made, one before and one after evacuation. I have had the privilege of studying dental conditions and the anatomy of the face with Prof. M. H. Cryer, at the Philadelphia Hospital, whose dry specimens and cases offered most thorough study in the exposition of the methods of stereoskiagraphy.

Professional Ethics.—A practitioner of medicine, to the best of his knowledge and ability, should strictly follow the code of *etiquette* accepted by the profession, for he may be assured that it has its root in a principle which works for the general good, while for his real success nothing in the end will prove more helpful than a faithful adherence to the spirit of the rule, "Do as you would be done by."—*British Medical Journal.*

BEHRING'S NEW TUBERCULOSIS REMEDY.

ARNOLD C. KLEBS, M.D.
CHICAGO.

"I can assure you that rarely in my life have I felt greater joy than during those days, weeks and months when I recognized with ever-growing clearness the essential causal relation between inoculation and immunity." These enthusiastic words were uttered by von Behring at the closing session of the International Congress of Tuberculosis October 7, of this year, before an assembly of lay and medical members and their guests. They served as an introduction to the revelation of this remedy of tuberculosis, of which we, who were in Paris at the time, had seen the most wonderful accounts on the preceding days in the sensational press of the French metropolis. It seems to be the specialty of international congresses to bring forth some sensational revelations. In 1890 Koch's announcement of his tuberculin and later in 1901 of his unbelief in the identity of the human and bovine type of the tubercle bacillus are still well remembered. The sensational element in this, as it was the case in the others, will exert a regrettable influence on the public and especially on its good opinion of things medical.

Anything uttered by the inventor of diphtheria antitoxin by a scientist of the first rank, however, must command attention, no matter how regrettable its mode of announcement may seem. The original text of Behring's address was translated by Letulle and Fuster. It may be presumed that this translation which was read at the congress in Behring's presence, was authorized by him. All the various English translations seem to have been made from this French translation. The only German text available so far is the one given in the *Münchener Medicinische Wochenschrift*, No. 43. There are some more or less important differences in the wording and actual text of these various articles. In quoting Behring I shall hold myself principally to the German text.

First of all, it may be suitable to examine what Behring promises to accomplish with his "new tuberculosis remedy." He says: "My method is destined, I believe, to protect men threatened with phthisis, against the damaging consequences of the infection." Ambiguous as these words are, we must take them to signify that the remedy is not expected to cure tuberculosis in all its stages, but to prevent in those infected the development of destructive processes, i. e., phthisis. Exactly where the efficiency of the remedy begins and ends is not indicated in the address.

This accepted, we may proceed to analyze his theory of a curative principle, the existence of which he says he has recognized with certainty during the last two years and which is entirely different from the antitoxic one. Here, again, is the same ambiguity of expression. He says "this new curative principle plays the essential rôle in the immunizing action of his 'bovo-vaccine.'" This latter method consists in the inoculation of cattle with human or other attenuated varieties of the tubercle bacillus in increasing doses until an immunity not only against these but also highly virulent bovine bacilli is obtained. The curative principle, he says, becomes active by the impregnation of the living body cells with a well-defined constituent of the tubercle bacillus. He has isolated this substance and calls it TC, as E. Klebs has done for long years to indicate the active curative principle contained in the cultures. Behring thinks his TC has formative, assimilating, absorbing qualities and thus constitutes the life principle of the bacillus. That Behring thinks he has been able to isolate the "life principle" of the bacillus *in vitro*, must be taken as the most direct indication of his intention as I will show later. This TC has remarkable qualities; he finds it has fermentative catalytic powers, even within the impregnated animal cells. It is responsible for the hyper-sensibility to tuberculin and the curative cellular reaction against the virus. The healing action is exerted through a transformation of this TC within the cell into some hypothetical derivative, which Behring calls TX, because he does not know yet whether it is a ponderable body or not. A cellular immunity quite different from the antitoxic, humoral immunity is thus produced, and Behring says that he has arrived at the clear conception of this through his intimate acquaintance with Metchnikoff's work on phagocytosis. Experimental proofs for this view he does not give us, however. He promises them in a new book which is to appear soon.

The method of preparation of his remedy is then sketched, and the fact that Behring and his school have made in the Behring works at Marburg the most exhaustive chemical and experimental investigations of the various components of the tubercle bacillus renders this part of the address of particular interest. These works, which were established at the expense of a well-known chemical firm, are the most perfect to be found anywhere and offer every opportunity for these studies. Several hundred thousand liters of bouillon media have been used there for the growth and subsequent study of the tubercle bacillus only. One who sees the scanty cultures in ordinary laboratories would be astonished to find here crops of tubercle bacilli weighing pounds. Apart from the laboratory facilities, there is offered every opportunity for experimentation on large and small animals also on a scale not to be found elsewhere. A staff of very able assistants working under one of the foremost bacteriologists of the age, and utilizing these facilities must produce results which of necessity compel attention. In speaking of the method of preparation of his TC, Behring considers three groups of substances which hinder its therapeutic action. We may note here that Behring, Römer and Ruppel have previously isolated and studied twenty-five separate substances derived from the bacillus by various methods. The three groups Behring refers to are; (1) One substance soluble in water and corresponding to Koch's tuberculin. By certain procedures he was able to increase its toxicity so that 1 gram of the substance is more powerful than 1 liter of the old tuberculin. (2) A proteid substance soluble only in neutral salts (NaCl). It is toxic like tuberculin. (3) A group of non-toxic substances soluble in alcohol, ether, chloroform, etc. The body of the bacillus, freed from these three groups of substances, Behring calls the rest-bacillus. He reduces it probably through grinding to an amorphous mass, and this is, although he does not state it directly, the TC. Introduced into the subcutaneous tissue of certain animals which are not immune to tuberculosis, he finds it is taken up by the cells which originate from the lymphatic germ centers. These cells transform the TC and become oxyphile and eosinophile simultaneously with the manifestation of bodily immunity. Behring considers it of fundamental importance for the comprehension of the therapeutic TC action, that although it is not itself capable of reproduction, tubercles can be produced by it, tubercles which never caseify or soften, but heal spontaneously without leaving traces (Laennec's granulations tuberculeuses).

These are about all the facts given in Behring's address. As to the method of applying his remedy (which he considers capable of improvement), no direct information is given. He only says that it can perhaps be modified with advantage.

Therefore, in order to get a conception of his theory of the new curative principle, of the nature of his remedy and its application, we must resort to speculation, and this is possible only with a due consideration of Behring's other recent work on immunization. Although Behring's language in his address is vague and ambiguous, there are certain essential principles which can not be misinterpreted. First of all among these is the fact that Behring finds the curative principle pre-existent within the body of the tubercle bacillus. This means an entirely new departure and radical change in Behring's opinion. In his introduction[1] to the work on cattle immunization against tuberculosis, we find this very positive statement: "We must for once and ever discard the teaching of the co-existence of curative and damaging agents within an infective substance (Bouchard's *matières vaccinantes* and *matieres nuisibles*)." In whatever way he may explain the action of his TC, we can consider it nothing else but a "matière vaccinante" extracted from the bacillary body.

He has been able to produce immunity against tuberculosis by the introduction into the circulation of living and self-producing tubercle-bacilli, but he has the "most serious objections" to the application of such a method in man. In TC he has found a substance which is not living and self-reproducing, but nevertheless "can be made far superior to the living bacillus in regard to its protective and curative action." There is certainly nothing very new in this discovery, and should it prove to be true it would be a brilliant vindication of E. Klebs' investigations which allowed him to adhere persistently to his theory of a curative element pre-existent in the tuberculous virus. Even before 1894, when this author published *in extenso* the results of his biochemical investigations of the tubercle bacillus, he defended his theory of the presence of a curative principle in the virus, which he then called, as Behring does now, TC. He has through all these years substantiated his theory by numerous tests on animals and in men. E. Klebs sees the mechanism of the immunizing process by his TC in its bactericidal action, and it can not be stated clearly from the works of Behring, how much he differs from him in this respect.

Behring speaks of a cellular immunity altogether different from the humoral antitoxic immunity, but the mechanism of this is by no means clear. In his work with Much,[2] the relations of cell life to certain (anthrax) infective organisms were studied with very interesting results. The conclusions then drawn were that not only cells suspended in body fluids are carriers of antibodies, but also fixed tissue cells can carry and produce them. Also that various infective substances show elective qualities for certain definite cell groups. In the case of tuberculosis, as we have seen, Behring has paid special attention to the germinative cell centers of lymphatic tissue. He has evidently studied these cells by similar methods, as was some time ago done by Donath and Landsteiner. There he came to the following hypothetical conclusions: The cells, leucocytes, endo- and epithelial cells in this case, during a course of a subacute or chronic infective process become victim to "oxyphile" degeneration (the less virulent the infection the more the oxyphilia, intense coloration by eosin), they are finally reduced to a colloidal solution which gives to the blood fluid the agglutinating properties against that variety of bacteria which has produced the infection. We have seen that Behring in his address says that the metamorphosis of the TC within the cells is accompanied by their oxyphile and eosinophile degeneration, and that this marks the manifestation of immunity. He does not state there what further changes take place in the cells and what part they play in the immunizing process. In the above-cited case (anthrax) he suspected that the modified cell substance acted through agglutination. It is very doubtful if this theory is applicable in the case of tuberculosis. But there is no doubt that these processes merit the great attention which they have received in very recent times. We know that Wright and Douglas have found in the blood plasma certain substances which they call opsonins. These substances, by becoming attached to the bacteria, make them (opsono: prepare as food) susceptible to phagocytosis. Whatever the mechanism of immunization in Behring's method may be, it appears very probable from the foregoing that he imagines a more or less direct bactericidal action to take place.

These considerations may throw some light on one of the darkest passages of Behring's address. It is: "I have transformed active into passive immunization." In Ehrlich's terminology we know that "active immunization" pre-supposes cell activity for the production of antibodies; in "passive immunization" the latter are artificially introduced into the body through a foreign serum rich in receptors. It may be that the "passive action" of the cell substance, as we have seen above, has given rise to this expression of Behring's. It certainly does not seem probable that Behring's method of application is based on what Ehrlich calls passive immunization. Behring, it is known, has substituted for Ehrlich's terms active and passive, "isopathic" and "antitoxic."

Since Behring expressly states that the new, by him discovered, curative principle plays the essential rôle in his immunization method of cattle, it is most probable that this latter has been followed by him here with some modification. We have seen that he objects to introducing into the human organism living tubercle bacilli. But since he has found that he can make these latter perfectly harmless, by extracting from them the TC, a substance of much greater protective and curative powers and which, he emphasizes, contains the life principle of the bacillus, we are forced therefrom to conclude that his method consists essentially, not as in cattle immunization in the introduction of living tubercle bacilli, but in that of the life principle, the TC. With this theory of the bacillary life principle he covers up another change of opinion, because only this year we find him saying: "My bovo-vaccine consists of living germs. If it is heated so that the germs are killed it ceases to be a vaccine. It may contain a poison, but it is not any more self-reproducing and the poison is not capable of exerting a protective action."[3]

The hypothesis that Behring intends to use the bacillary product TC directly for immunization purposes, I believe, is strengthened by his most recent contribution to the subject in a letter to the November number of the *Revue Internationale de la Tuberculose*. He speaks there of his intention to use the unstable remedy TX in man, while the mother substance, the TC, which is more preservable, is to be used in animals, but he adds: "It is not impossible that later TC will be employed advantageously in man." He says, also, that he has extracted the TX from the animal body and compares it to an explosive substance, probably indicating thereby its instability. From what has been said before it seems quite likely that he has used for extracting purposes the lymphatic tissue, possibly the bone-marrow of cattle. The fact, however, of his extracting the TX for experimental purposes does not at all detract from the significant fact expressed by him that he thinks it possible that ultimately the TC can be used directly for curative purposes.

[3] "Beiträge," No. 10, p. 2.

With a knowledge of Behring's ideas of cattle immunization we are allowed to presume that in human immunization with TC or TX he will introduce this substance by the same way. He has chosen the quickest and shortest routes to the points of attack of the tubercle virus, which he believes to be the leucocytes and the non-striated muscle-fibres, i. e., through the blood-current. He finds by this method the elective attraction between polynuclear leucocytes and the tubercle bacilli brought about very rapidly and especially in animals which previously have been under the influence of the tubercle virus. We see here again how much importance he ascribes to the cellular conditions.

The results of recent clinical studies of leucocytosis and phagocytosis have a direct bearing on these questions. Arneth's investigations[4] of series of neutrophile blood pictures, made on a very extensive scale, have allowed him to come to certain definite conclusions in regard to tuberculosis immunity. He is led to believe that the injected quantities of toxins (tuberculin in this case) according to their dose destroy a larger or smaller quantity of neutrophile leucocytes or what he considers the same, that for the production of antibodies a corresponding number of cells is needed and used up. To replace the loss created by this increased consumption of cells a more or less stormy production of cells (leucocytosis) follows. This increase of functional fitness is shown by an ever-increasing production of antibodies which with the consumption of the cells enter the blood in corresponding quantities, thus enabling the organism to overcome increasing doses of toxins without reaction, i. e., to become immune. This seems to be supporting Behring's theory of a cellular or histogenetic immunity, or better, it revives the interest in Metchnikoff's theory of phagocytosis. Metchnikoff has persistently adhered to the fact demonstrated by him, of a phagocytic derivation of antibodies. In this respect the careful studies of phagocytosis inaugurated by the Belgian investigators, Denys and Leclef, will also have to receive renewed attention.

There is, however, a large group of careful investigators who adhere to the humorigenic origin of the antibodies, whether they be antitoxins, lysins, agglutinins, precipitins or opsonins. The results of the recent experiments of Wright and Douglas, which were confirmed by Bulloch and Atkin, Hektoen and Ruediger and others, are certainly more in favor of the humorigenic theory of immunization, and the practical results of the "vaccination" method based thereon can perhaps be regarded as further supporting it.

We have seen that Behring considers it of importance in his method of cattle immunization that the attenuated virus is brought rapidly to those preferred points of attack of the virus, and that he had to utilize the blood current for the purpose. Whether he believes this sufficient for curative purposes in man must remain problematical until we hear more from him in this respect. Loewenstein's very recent studies[5] of experimental iris tuberculosis give suggestions in this direction, which to some extent have been already elaborated by Koch and his school. He finds that purely local infections do not bring about a formation of agglutinins, and from that he concludes that neither acute local or chronic infections (the latter being always local) can bring about an immunity, which is so easily produced in acute general infections. To treat chronic infections successfully he thinks it necessary that "other organs than those especially sensitive to the infection must be forced to absorb the specific infective bodies."

Considering once more Behring's announcement in the light of his own and other experimental studies, we are allowed to conclude that he has entered on a new line of work and that his further reports will merit great attention. On the whole, it seems that his method is based on principles, elaborated before him by others, especially Metchnikoff and E. Klebs. How much ultimately suffering mankind is to profit can not be predicted, nor can Behring's expressed, though carefully and ambiguously worded expectations, mean anything but a plausible, by him yet unproved hypothesis of a curative principle, applicable in human tuberculosis.

Special Article

THE PHARMACOPEIA AND PHYSICIANS.

CHAPTER I.

INTRODUCTION.

The Pharmacopeia of the United States of America has been the generally accepted authority and the professed guide of American medical men, in matters therapeutic and pharmaceutic, for over eighty-five years. Since the publication of the first edition, in 1820, the book has undergone eight decennial revisions and to-day it is universally accepted as being the peer of authoritative books of its kind, for its scientific accuracy as well as for the general excellence of the descriptions and directions that it contains.

This recognized superiority of the Pharmacopeia of the United States of America, in its own particular field, and its generally accepted authority, as a guide, in all matters relating to the strength and purity of the medicinal articles enumerated in its pages, is all the more remarkable in that during its long and varied career it has never been granted a general recognition by statutory enactment. This lack of legal recognition has undoubtedly been a disadvantage to the book in so far, that, in the past two decades at least, the contents and even the very existence of such an authoritative book has been largely lost sight of by American physicians, and official remedies, to a very marked degree, have been eclipsed or overshadowed by the innumerable patented and proprietary remedies that are constantly brought to the attention of medical men in the advertising material with which their offices are regularly deluged.

With a view of bringing the Pharmacopeia itself, its scope and its contents, and particularly the extensiveness as well as the comprehensiveness of the included material, more prominently before the medical profession, it is proposed to present, in a series of articles, a collection of facts and suggestions bearing on the number and the variety of therapeutic indications that may be fully met with official drugs and preparations.

It is also proposed to call attention to the unreasonable claims and the extraordinary statements that are frequently made in connection with some of the arbitrary combinations of drugs that are offered as proprietary remedies or "patent" medicines, and to compare the probable limitations of these self-styled panaceas with the possible application and the varied uses of the more simple and, therefore, more generally reliable, official remedies, the composition as well as the purity of which can readily be determined by well known and easily applied methods.

---

[4] Leube's Clinic.

[5] Moeller's laboratory at Belzig.

That even the most recent, the eighth decennial, revision of the Pharmacopeia can not be said to be free from possible errors of commission and omission must be admitted, but many of the shortcomings that are usually attributed to the book are really due to the general lack of interest that has been displayed by physicians; and many, if not all, of these shortcomings should be corrected in future revisions, if members of the medical profession would but make their needs and wishes known at the proper time and place.

It has been repeatedly asserted that the Pharmacopeia of the United States, as such, is designed primarily for pharmacists and for the manufacturers of pharmaceutical galenicals, and that it contains little or nothing of direct interest to the physician. One of the prime objects of this series of articles will be to demonstrate that this assertion embodies only a half truth and that the present edition of our national Pharmacopeia really contains much that does, or at least should, interest every medical practitioner in the land.

In this connection it should also be remembered that the technical descriptions and tests for which the average physician may think he has little or no use, are in reality essentially important in securing for him, and through him for his patients, remedies that are not only reliable, but which are also uniformly active.

As an introductory to this proposed series of articles, it may be permissible to give a brief review of the history of our national Pharmacopeia and incidentally to call attention to at least some of the various causes that have led up to the present widespread use of proprietary medicines and nostrums. To do this it will be necessary to call attention to some of the shortcomings of our Pharmacopeia, from a medical point of view, and to refer to at least several of the attempts that have been made to correct these shortcomings by offering either a substitute book or by introducing more or less radical changes in the book itself.

During the colonial period, and even during the first three decades of the independence of the United States, the pharmacopeias, or the dispensatories that were based on the pharmacopeias of Edinburgh, London and Dublin, in the order given, were practically the only authoritative books on materia medica known in this country.

A rather notable exception is to be found in the small pamphlet, of 32 duodecimo pages, containing 100 titles, that was published as "A Pharmacopeia for the use of the Military Hospital belonging to the Army of the United States," during the Revolutionary period. The first edition of this little book was published in 1778 and a second edition, bearing the name of Dr. William Brown as editor, was printed in 1781.

The earliest known attempt to produce a distinctly representative American Pharmacopeia was made by the members of the College of Physicians, who, June 1, 1788, appointed a committee of eight members to form a pharmacopeia for the use of the college. The members of this committee, being desirous "that the work should be accommodated to the practice of medicine throughout the United States," continued the preliminary work and correspondence for over ten years, but finally allowed the project to languish.

Recognizing the need for a more distinctly American book, Dr. J. Redman Coxe, of the University of Pennsylvania, in 1806, published what was practically a reprint of Duncan's Edinburgh Dispensatory, under the title of "The American Dispensatory." The next American publication, in point of time, was the Pharmacopeia of the Massachusetts Medical Society, published in 1808, and this was followed in 1810 by Dr. James Thacher's American New Dispensatory, also published in Boston. These books supplied two of the then existing medical centers, and the territory more or less dependent on them, with reference books on materia medica, of American origin. The territory more directly dependent on New York City was in a measure supplied by the publication of "The Pharmacopeia of the New York Hospital," in 1816, and the subsequent publication, in 1818, of an American reprint of the Edinburgh New Dispensatory. This rapid multiplication of authoritative books appears to have been unsatisfactory and no doubt led to the revival of the project, proposed many years before, of forming a truly national pharmacopeia.

American physicians, and particularly the leaders in American medicine, have contributed so little to the evolution or advancement of the Pharmacopeia of the United States of America, during recent decades, that, no doubt, it will be interesting, if not surprising, to many, to be reminded of the fact that the inception as well as the inauguration of the Pharmacopeia is to be accredited to the leading minds in the medical profession of this country, eighty or more years ago. It was at a meeting of the New York County Medical Society, in January, 1817, that Lyman Spalding suggested the first practicable plan for securing a national pharmacopeia. At the annual meeting of the Medical Society of the State of New York, held at Albany, in February, 1817, the same plan was discussed and a committee was appointed to consider the necessary details and to report at the next annual meeting. The report of this committee being in favor of the proposed plan, the society, in 1818, appointed delegates to meet in district convention, for the purpose of forming a pharmacopeia. Of the members of the New York State Medical Society who took an active part in forming this first national pharmacopeia it may be well to mention the names of Lyman Spalding, Samuel L. Mitchill, David Hosack, Valentine Mott, T. Romeyn Beck, Wright Post and Alexander H. Stevens. Other members of the profession were hardly less enthusiastic. In Boston the proposed plan received the earnest support of John C. Warren, Jacob Bigelow, James Thacher and George C. Shattuck. In New Haven it was endorsed by Eli Ives, William Tully and Nathan Smith; in Baltimore by Elisha DeButts, Samuel Baker and Nathaniel Potter, while in Philadelphia, Thomas T. Hewson, Samuel P. Griffiths, Thomas C. James, Edwin A. Atlee and Joseph Parrish, all of them active and influential members of the College of Physicians, gave the plan their unqualified support and endorsement.

On Jan. 1, 1820, the first General Medical Convention was convened at the Capitol, in the City of Washington, for the purpose of preparing and publishing a national pharmacopeia. The convention was organized by electing Samuel L. Mitchill, New York, president, and Thomas T. Hewson, Philadelphia, secretary. The necessary details connected with the preparing, publishing and editing of the proposed pharmacopeia were entrusted to a committee composed of Drs. Lyman Spalding, Thomas T. Hewson, Eli Ives, Elisha DeButts and Jacob Bigelow. The copyright of "The Pharmacopeia of the United States of America" was subsequently sold to Charles Ewer, of Boston, "for a large sum" and the book was finally published under date of "Dec., 1820."

This completed pharmacopeia, although prepared and edited by a committee of the most prominent medical men of the day, and printed in Latin, as well as in English, was soon found to be "in its nature too circumscribed and technical" for the use of physicians.

To overcome this necessarily objectionable feature and to popularize the book and its contents with medical practitioners, Dr. Jacob Bigelow, a well-known medical writer and one of the editors of this first national pharmacopeia, in 1822, published what he was pleased to term "A Treatise on the Materia Medica, Intended as a Sequel to the Pharmacopeia of the United States, Being an Account of the Origin, Qualities and Medical Uses of the Articles and Compounds which Constitute that Work, with Their Modes of Prescription and Administration." This book, practically a pharmacopeia for physicians, appears to have met with considerable popularity, and the well-worn pages of the still existing copies of the book certainly appear to bear evidence to the fact that they were frequently consulted.

That a pharmacopeia, consisting largely of a simple enumeration of drugs with detailed directions for the several medicinal preparations, could not be expected to appeal to the medical profession, and that, unless such a book was well known to the individual members of that profession, it would have little or no reasonable excuse for its existence, appears to have been clearly appreciated by the members of the medical convention that met in the city of New York in January, 1830, for the purpose of revising the pharmacopeia.

The members of this convention decided to, and subsequently did, introduce several really novel features into this first revision that are only now, three-quarters of a century after the publication of the book, being revived and discussed. In addition to having short descriptions of the physical properties of drugs, both whole and powdered, this Pharmacopeia also included doses, and, what is even more, also included short, suggestive remarks on the "Medicinal Operations" or therapeutic properties of the several drugs that were included in the text.

For some unknown, certainly unforeseen, reason there appears to have been a misunderstanding in regard to the method of electing delegates to attend the General Medical Convention, and at least a portion of the delegates from the Middle States did not attend the convention in New York, but decided to hold a convention of their own in the city of Washington. As a direct outcome of this opposition convention we have another, "first" revision of the national Pharmacopeia, published in Philadelphia in 1831.

This 1830, Philadelphia revision of the national Pharmacopeia, as it is generally known, was continued along practically the same lines as the original pharmacopeia published in Boston in 1820 and did not appear to meet with the use and sale among physicians that its authors might reasonably have expected or desired.

To popularize this edition of the pharmacopeia, and also to furnish American medical practitioners with a convenient handbook on therapeutics, two of the younger members of the committee on revision, Drs. George B. Wood and Franklin Bache, decided to prepare and to publish a commentary on the national Pharmacopeia. This book, known as the "Dispensatory of the United States of America," first published in 1833, met with instantaneous and really phenomenal success. Three editions were sent to press within as many years and the book rapidly displaced the Pharmacopeia itself with both physicians and apothecaries, and led to the rather anomalous condition of having a commentary that was generally accepted as being more popular and, therefore, more important than the Pharmacopeia itself.

For more than fifty years the Pharmacopeia occupied such a secondary and comparatively unimportant position to the Dispensatory that it was generally asserted that it would be practically impossible to have the Pharmacopeia published apart from the Dispensatory. Fortunately the authors of the Dispensatory were men of exceptionally high ideals and for over fifty years were the leading contributors to the advance and progress of the Pharmacopeia itself.

That the unrelenting hand of time brings changes that stay progress was evidenced in 1876, when Dr. E. R. Squibb, of Brooklyn called the attention of the members of the American Medical Association to the fact that the then official Pharmacopeia could not be said to represent the existing status of the practice of medicine and pharmacy. Dr. Squibb also pointed out that, owing no doubt to the death of one of the editors of the United States Dispensatory, Dr. Franklin Bache, and the very advanced age and practical retirement of Dr. George B. Wood, that book had not been carefully revised, or brought up to date, and, therefore, that the medical profession was entirely devoid of any authoritative work on materia medica and pharmacy.

To overcome the evident stagnation that had crept into the revision of the national Pharmacopeia, at that time, Dr. Squibb proposed that future revisions be undertaken by and conducted under the supervision of the American Medical Association. This latter proposition met with such active and bitter opposition, however, that in 1877 future consideration of this project was indefinitely postponed.

During the decade immediately following this discussion, there arose a number of additional factors to detract from the popularity and from the general use of the national Pharmacopeia. Not the least of these is to be found in the innovations that were included in the 1880, sixth decennial, revision of the Pharmacopeia itself. This is a subject that is more of pharmaceutic than therapeutic interest, however, and its further consideration may be omitted at this time.

One other factor, and not by any means an unimportant one, from an economic point of view, was the introduction of German synthetic chemicals, and the accompanying scramble for publicity by ambitious, professedly up-to-date medical practitioners in the reading pages of our medical journals.

Kairin, the first of these synthetic products to reach us, was introduced in 1883, and soon proved to be not only unreliable, but positively dangerous. It was followed, in 1884, by antipyrin, which met with phenomenal use and added untold wealth to the coffers of the manufacturer. The commercial success of this substance stimulated others to renewed activity, and in the succeeding years American physicians were deluged by an immense number of really useful, as well as positively dangerous, true and fictitious, synthetic remedies, to say nothing of the untold hundreds of elegant pharmaceuticals, all of them lauded and exploited as new remedies.

This rapid accumulation of true, as well as of pseudo, new, remedies appears to have had a stimulating effect on the editors of the several dispensatories and text-books on materia medica and therapeutics. These books rapidly grew in size and weight and also in the variety of the contained material until the official or pharmacopeial portion was lost in the superabundance of wonderful cures and remedies that were offered for the alleviation of the ills and ailments of the human family. Added to all this plethora of new remedies, there appeared a growing feeling in favor of therapeutic nihilism until it was quite proper for a physician to disclaim all knowledge of the use of drugs and boldly to assert that he was entirely independent of the necessity for such really antiquated measures as drug therapy.

The publication of the 1890, or seventh decennial revision, of the national Pharmacopeia offered or suggested but little change in the then existing conditions other than to reintroduce the long-established English practice of measuring liquids and weighing solids. Even this concession did not appear to have the desired effect of popularizing the Pharmacopeia. This no doubt was due largely to the fact that pharmacists are proverbially slow in adopting new ideas, and physicians are even slower, or are loth to insist on rational innovations being adopted wherever practicable.

With the advent of the new century, there appears to have been a re-awakening on the part of the members of the medical profession, at least, and the interest that has been manifested in the work of the Council on Pharmacy and Chemistry of the American Medical Association, the articles that have appeared in lay journals on the abuse of nostrums by the laity and, last but by no means least, the comments that have appeared in medical journals on the contents of, and the changes that have been made in, the recently issued eighth decennial revision of the Pharmacopeia of the United States of America all bear evidence to the existence of a healthy spirit of inquiry among medical practitioners in this country.

As noted before, it is to foster and to aid this spirit of inquiry and to present what, at times perhaps, may be seemingly elementary information on a well-known subject, that this series of articles has been designed. If they but tend to make the members of the medical profession more familiar with at least some of the numerous drugs and preparations that are included in the pages of our national Pharmacopeia the time that has been devoted to their preparation will not have been spent in vain, or the space in these columns wasted.

The Local Use of Tetanus Antitoxin.—An employé of the Behring Institute at Marburg, who had had tetanus twice, was accidentally inoculated in the right hand with a virulent culture of tetanus. Kuster of Marburg reports in the *Wiener klin. therap. Wochschr.* that the wound was washed and treated with antitoxin, but marked tetanus of the right arm soon ensued. The axilla was then laid open and all the nerve stems thoroughly injected with tetanus antitoxin. In twelve hours the stiffness of the arm musculature had disappeared and only a slight temporary trismus remained, due perhaps to a small amount of the toxin having been carried to the spinal cord before the blocking off in the nerve trunks.

THE PHYSICIAN AND THE PHARMACOPEIA.

It is easy to pull down, but difficult to build up.

A fool can destroy; it usually requires a genius to create.

Destructive criticism accomplishes little, often reacts and does an injury to whatever the cause may be.

Calling attention to a harmful condition of affairs, without exaggeration, and at the same time suggesting a means whereby the harmful conditions may be improved, usually brings about a better state of affairs; it never makes them worse.

For some months we have been calling attention to the nostrum evil, occasionally specifying, by name, articles that are for one reason or another fraudulent and mentioning individual firms who are deliberately deluding members of our profession by exploiting through them articles that are nostrums in the worst meaning of the word. This we shall continue to do.

We have also been calling attention to the deplorable condition that has developed by allowing unprincipled promoters—the larger number of whom know little of medicine, pharmacy or chemistry—to blight our therapeutic literature by polluting it with false or misleading statements, extravagant claims, and by publishing valueless testimonials obtained from credulous and ignorant or unthinking physicians. This, also, we shall continue to do.

All this might be called destructive criticism, and probably if we stopped at this we should accomplish little of permanent value. Construction as regards the good, as well as destruction of the bad, must be the aim. A general condemnation of all proprietary medicines is not wise and is liable to produce a species of therapeutic nihilism in a few and to have the opposite effect on the many. (However, we are not in this country suffering from too much therapeutic nihilism; the proprietary medicine men—even those who have honest, non-secret, commendable products must be included—have generously supplied us with literature so overly colored with hopefulness that it has developed a therapeutic optimism that is much more baneful than any therapeutic nihilism could be.)

Proprietary medicines,[1] as such, are not to be condemned. Some are valuable additions to our materia medica and represent advanced knowledge in chemistry, as well as in pharmacy. Those preparations, whether patented or not, which accord with the principles contained in the ten rules adopted by the Council on Pharmacy and Chemistry of the American Medical Association will be described and the description published to the profession in due time.

But something more must be done than simply to condemn the bad and to recognize the good if the present conditions are to be changed. It is repeatedly stated—and there is no doubt of the truth of the statement—that medical practitioners are incompletely prepared either to see the fallacies of the promoter's optimism or to prescribe easily for every condition without leaning on the crutches of ready-made mixtures. There is need of education here, and this education must reach both those who are about to enter our profession and those now in active practice. The young men who are now in medical colleges must at least be taught how to write prescriptions, and they should be warned of the wiles of the nostrum vendor before they are given the privilege to practice medicine, even though pathology and bacteriology have to be neglected. Then, too, something must be done to counteract on those now in active practice the influence of the too-often erroneous literature of the nostrum exploiter, as well as that of the smooth-voiced, oily-tongued, well-trained "detail man," who knows so well how to bamboozle and cajole the unwary and uninformed doctor. Further, we must recognize the fact that most of us need educating over again as regards our method of prescribing. If we are to give up using nostrums, and if we are to refuse to accept our therapeutic literature from those who are making fortunes from our acting as unpaid peddlers of such articles, we must learn what we can substitute for them and must obtain our therapeutic hints from other sources.

With the object of helping to solve one phase of the problem, The Journal proposes to present to its readers a series of articles on the relation of the physician to the Pharmacopeia. The character of these articles is outlined in the introduction which appears this week. We feel sure that they will enlighten us regarding official remedies, which have been sadly neglected by our medical schools, by medical journals, and even by authors of text-books. They will show that in the Pharmacopeia we have such a wealth of therapeutic agents that there is no real necessity for using anything not official; at least that there is no necessity for using nostrums. The basis of these articles is the Pharmacopeia, and, except incidentally, only official drugs will be discussed. In the near future the proprietary preparations which have been indorsed by the Council on Pharmacy and Chemistry will be published, probably first in The Journal, in a series of articles to follow those now begun on the official preparations.

THE NEW ORLEANS IMBROGLIO.

The entire state board of health of Louisiana has resigned, including the president, Dr. Edmond Souchon. Following the submission to Governor Blanchard of their report on the epidemic of yellow fever, it is said that the governor announced that he wanted an investigation of the circumstances responsible for the entrance of yellow-fever infection. He expressed the intention to ask a grand jury to determine who, if any one, had failed to do his duty. Thereon the board resigned. In its report the board concludes that it is not possible to decide the source of the original infection, but it presents probable hypotheses. It points out that in July a physician at Gulfport, Miss., was fined for reporting a doubtful case of yellow fever, though many cases subsequently developed in Gulfport, and though Governor Vardaman later severely scored physicians who did not promptly report cases. "Ship Island [quarantine station] is close to Gulfport; so is New Orleans, and the inference is obvious." Colon and Havana are suggested as possible sources of infection, as are Bocas del Toro, Belize and Port Cortez. The board suggests that the officers of our Public Health and Marine-Hospital Service stationed at Belize and Cortez did not learn of yellow fever at those ports until several weeks after the early cases occurred. Complaint is made that the Surgeon General of the Public Health and Marine-Hospital Service did not order the fumigation of empty vessel holds at infected Colon until requested to do so in June by President Souchon. It is pretty squarely charged that Havana concealed cases for months, and Cuba's quarantine system is declared to be a farce. It is also alleged that early in the summer one man twice came from infected Vera Cruz and entered Texas at Laredo without any difficulty. It is recommended that the quarantine season be advanced to begin on March 1, and that the detention period be made six days instead of five.

"The State Board of Health positively denies the statement of Dr. Kohnke in his official report" that he informed the board of suspicious cases early in July. Dr. Souchon says he received the first news of cases from physicians and notified Dr. Kohnke, and Dr. Kohnke, in his report as published, makes the same statement. In justification of its course the board makes one plea that carries weight. From the day when the first suspicious case was reported several days had to elapse before a positive diagnosis could be made, and to announce prior to demonstration that yellow fever existed would have thrown business into useless turmoil.

In our issue of two weeks ago it was noted that the chief count in the indictment brought against the Louisiana health officials by the public, and especially by the Mississippi authorities, was the fact that reduced-fare railroad excursions into New Orleans from neighboring towns and states on July 19 were permitted without warning of danger to bring great crowds into an infected city. This is based on the fact recorded by Dr. Souchon and Dr. Kohnke that the first suspicious cases were reported on July 12 and again on July 15. Dr. Souchon reports that he saw two cases on July 18 at the Hotel Dieu "presenting symptoms of yellow fever." He called a meeting of the state board of health for July 19 (the very day the excursionists were in the city), at which meeting a resolution was passed "instructing President Souchon to write to Dr. Wyman, Dr. Tabor of Texas, Dr. Hunter of Mississippi, and Dr. Sanders of Alabama that there were cases here presenting symptoms of yellow fever, and also to wire them to expect a letter by to-day's mail." The first positive diagnosis confirmed by autopsy findings was made on July 22.

So far as present information goes, therefore, it is impossible fairly to charge the Louisiana authorities with deliberate concealment. Of course, it was the very acme of unfortunate mischance that a popular excursion to New Orleans should have been run during the very days when the diagnosis necessarily was in doubt. Mere suspicion of infection would not have justified the alarm aroused by canceling the excursions, nor is there the least evidence that the authorities knew that the infection was sufficiently widespread to endanger the excursionists of a day. Of course, it is also only too evident that the real early cases, those during May and June, were not reported to the authorities nor found by inspection. In part this was due to the misleading mildness of the atypical first cases and to the consequent and wholly excusable failure of diagnosis, but, it is to be feared, in further part to concealment of cases by a few physicians practicing among the Italians.

In New Orleans, as elsewhere in this country, the public and the authorities have not secured effective *sanitary organization*, with all its requirements and restrictions. From this defect in preparation as the fundamental factor arise such controversies as the present one in New Orleans. This one could have been avoided had the community heeded the pleadings of Dr. Kohnke, three years previously, that scientific preparations be made to meet a possible yellow-fever infection.

PHYSICIANS IN RELATION TO PUBLIC HEALTH WORK.

Dr. Wesbrook[1] emphasizes the difficulties in the way of securing adequate care for the public health, and suggests certain remedies for the difficulties in regard to the value of which there is little or no room for difference of opinion. We wish to lay special stress on the service that medical men in general may render public health by at all times upholding the need of special training and expert knowledge in this branch of public work, not only on part of laboratory men, but also on the part of health officials, state and municipal. Most of these officers are appointive, and many no doubt often conscientious executives appear to believe that any reputab physician is fully competent to be commissioner of health of a city or secretary of a state board of health. This is a dangerous tendency that frequently robs the public of the full benefits of modern public health science. It is self-evident that the person who is to direct the sanitary activities, with their numerous ramifications in different directions, of a great city or of a whole state can not do so properly if he has been largely out of touch with the recent development of public health science, as necessarily must be the case with the physician whose time and energy are devoted to medical practice in the usual sense. Indeed, we doubt whether physicians thoroughly appreciate the great growth of this science in recent years. Dr. Wesbrook's address gives us some idea of this growth, with its corresponding specialization. We observe that it is quite impossible for one man to be expert in all the branches of science concerned with public health; the most that can be expected is that he has a broad basis of general knowledge on which he has specialized in some particular direction. Now our appointing powers must be thoroughly informed of this new order of things in the hope that specialization in public health science may be better appreciated and the public welfare promoted.

---

[1] See page 1835.

While physicians advance public health through their advice, their rules and their example, it is very important indeed that they should fully recognize the tremendous importance to the prevention of acute communicable diseases that outbreaks of these diseases be recognized early. This means an early and correct diagnosis. In scarlet fever and smallpox it is doubtful whether laboratory methods as yet can aid in diagnosis except by way of exclusion, but in several other infectious diseases, notably typhoid fever, cholera, dysentery, these methods may be the means of settling the diagnosis before the clinical picture has become so characteristic as to remove all doubt. Hence physicians should not hesitate in doubtful cases of probable infection to call on the municipal or state laboratories for help. It is to be feared that in many cases apathy, and neglect to utilize the means at hand, lead to delay in the diagnosis of infectious and communicable diseases. Increased knowledge and increased facilities for prompt work lead to increased responsibility on part of the physician who now no longer can afford to take any chances with the mild case of suspicious throat diseases or of possible typhoid.

Of course, Dr. Wesbrook's suggestion in regard to a traveling laboratory is an excellent one, but we believe that there is and always will be great need for fully equipped local laboratories arranged to meet the needs of larger and smaller districts. Certainly every city of 10,000 and upward should have its own laboratory, just as well as its own hospital. While the practical management of these local laboratories remains to be worked out, there is no question but that one of the great needs of practical medicine and public health now is to bring modern means of exact diagnosis as near to the door of [illegible] private practitioner as possible.

MULTIPLE PRIMARY MALIGNANT TUMORS.

Among the striking characteristics of tumor growth that are of importance in considering the various theories of tumor causation is its specific unity. A tumor begins to grow in one place at one time with so few exceptions that this unity may be considered as a rule of growth. A tumor may grow in an organ containing several types of tissue, but only one of these types assumes malignancy, and this one alone persists malignant until the end. A tumor in the breast may start from the epithelium and form a carcinoma, or it may start in the connective tissue and form a sarcoma, but as yet no one has described a tumor of the breast that started from both structures and was a mixed "sarcocarcinoma." The carcinoma may produce secondary growths in a strictly connective-tissue structure, for example a vertebra, but the secondary growth will still, without a single known exception, be a carcinoma. If the sarcoma produces secondary growths in an epithelial organ, say the liver, the secondary growths will invariably be sarcomas. The cause of sarcoma must, then, be looked on as having a specific nature, so specific that it can not produce a carcinoma even when in a place where the epithelial elements vastly predominate; the cause of carcinoma must be equally specific.

Of such significance is this rule of growth that the question of its exceptions becomes of great importance. How often and under what conditions do primary tumors occur simultaneously in different places in the same individual, and how often do primary tumors of different natures occur in the same place at the same time, forming a tumor composed of two sorts of malignant tissue at once? Occasionally reports have been made of cases of multiple primary tumor formation in which the individual has had distinct primary growths arising in different places either at one time or at different periods of time. Usually both tumors are of the same character, and generally they are carcinomas. One of the most commonly observed of these is the formation of independent skin carcinomas on different portions of the body, particularly in the aged. Nehrkorn has even observed three such independent primary growths in different portions of the intestinal tract in which the histologic structure was so distinct as to guarantee the independence of the growth—for example, a squamous cell carcinoma of the esophagus and a cylindrical cell carcinoma of the stomach. Van Hansemann was able to collect but twenty-two cases in the literature in which patients had had a carcinoma in one part of the gastrointestinal tract and another in some other part of the body at the same time, and in none were more than two primary growths observed. In spite of their close functional relation, however, and the frequence of primary tumors in each organ, only two or three cases have been reported in which a patient suffered with carcinoma in the uterus and in the mammary gland at the same time. There are more instances of simultaneous growths in the uterus and ovaries, but the ease of extension and metastasis from one to the other makes these cases more uncertain. The same difficulty exists in the cases of apparent primary carcinoma and sarcoma of both ovaries, of which many have been reported.

The simultaneous occurrence of carcinomas and sarcomas is even less frequent, particularly if we exclude a number of the cases of such tumors in the uterus or ovaries, in which the observers have evidently been misled by the peculiar sarcoma-like character of the cells of the stroma of the ovary and submucosa of the uterus. The most valuable of these cases are those in which separate metastases of sarcoma and of carcinoma have been found, and of these there are less than half a dozen. Such a case is that reported by Grawitz, the patient being a woman of 67 years, who, in addition to several benign myomas of the uterus, had a sarcoma of the uterus and a carcinoma of the small intestine, each of which had produced metastases of its own kind in other organs.

Most interesting of all are the tumors which contain both sarcomatous and carcinomatous elements in the same primary growth. If we consider the relation of prolonged irritation to the production of malignant proliferation of cells, we might reasonably expect, from this cause alone, that the rapidly-growing, irritated and inflamed stroma of a carcinoma might take on proliferation of a malignant type. Or if we consider Cohnheim's theory that tumors arise from misplaced nests of embryonal tissue, and that most of such nests (e. g., adrenal nests in the kidney) contain both epithelial and connective tissue structures, we might expect that both types would take on malignant proliferation at the same time. In spite of both of these possibilities, however, such primary mixed tumors are among the rarest of occurrences—there are scarcely a dozen cases reported. For some unknown reason they are most frequently present in the thyroid, and hence have usually been secured as surgical specimens by operation. Perhaps on this account in but one of these cases has the final conclusive evidence of dual nature been shown; that is, the production of metastases containing both types of cells. This was a "sarco-carcinoma" of the thyroid of a dog, reported by Wells,[1] which produced metastases of pure carcinoma, pure sarcoma, and of the mixed sarco-carcinomatous tissue. Other cases of sarco-carcinoma have been reported in this country—in the white rat by Leo Loeb[2] and in the human thyroid by Wooley.[3]

If we try to secure light on the theories of tumor etiology from these observations, we do not find the illumination a very clear one. Only the distinctly specific nature of carcinoma and sarcoma stand forward; that so few mixed or multiple growths have been examined shows that the cause of carcinoma is probably quite distinct from that of a sarcoma. This fact might be interpreted equally well in favor of the idea of a specific parasite, or of the theory of an inherent, fundamental change in the process of cell multiplication—the two prevailing theories. That multiple primary tumors are so rare surely controverts the theory of a "tumor diathesis" and also, to some extent, speaks against the idea of hereditary influence; the laws of chance would account for the small number of cases that have been reported. Grawitz considers that the infrequence of multiplicity speaks against an infectious origin, an idea with which we can scarcely agree, for how often do we have primary simultaneous infections of different organs by pathogenic bacteria?

In considering unusual pathologic conditions, such as these mixed tumors, a point of regret to the pathologist is that the great majority of such cases do not get into the literature. It would probably be safe to estimate that there occur a score of cases of multiple primary malignant tumors for every one that is reported. They are recognized by physicians frequently enough, and perhaps talked over among colleagues, but, not being recorded in the literature, their chief value is lost. No one man can have a large enough acquaintance with the rarities of pathology to draw safe conclusions from them. It is necessary to collect a large number of individual experiences to make deductions, which in many instances are of great importance in matters that are not uncommon. It is, therefore, a very real duty of every physician to make his own observations on unusual matters available to others. A careful report of any of the unusual conditions personally observed has a more permanent worth than a score of articles which contain merely reflections resulting from considering the writings of others, no matter how well presented and how instructive they may be. The man who has a case of acromegaly, or of acute yellow atrophy, or carotid gland tumor, or of blastomycosis, or of any of the other important but rare diseases, and does not make the facts available to others, is committing a sin of omission.

BEHRING'S NEW REMEDY FOR TUBERCULOSIS.

The summary by Dr. Klebs, in this issue, of Behring's address at the International Congrès for Tuberculosis gives us as clear an idea as at present attainable of the real gist of this matter. Shorn of bewildering detail and ambiguities, Behring's method consists in the use, for protective and curative purposes, of certain otherwise harmless constituents of the tubercle bacillus. The method appears to be a natural outgrowth of the successful immunization of cattle against bovine tuberculosis by means of injections of human and other varieties of tubercle bacilli. The introduction of living tubercle bacilli into human beings is not practicable and consequently it became necessary to try to secure the immunizing and possibly also curative substance or physician is fully competent to be commissioner of health of a city or secretary of a state board of health. This is a dangerous tendency that frequently robs the public of the full benefits of modern public health science. It is self-evident that the person who is to direct the sanitary activities, with their numerous ramifications in different directions, of a great city or of a whole state can not do so properly if he has been largely out of touch with the recent development of public health science, as necessarily must be the case with the physician whose time and energy are devoted to medical practice in the usual sense. Indeed, we doubt whether physicians thoroughly appreciate the great growth of this science in recent years. Dr. Wesbrook's address gives us some idea of this growth, with its corresponding specialization. While the practical management of these local laboratories remains to be worked out, there is no question but that one of the great needs of practical medicine and public health now is to bring modern means of exact diagnosis as near to the door of the private practitioner as possible.

MULTIPLE PRIMARY MALIGNANT TUMORS.

Among the striking characteristics of tumor growth that are of importance in considering the various theories of tumor causation is its specific unity. A tumor begins to grow in one place at one time with so few exceptions that this unity may be considered as a rule of growth. A tumor may grow in an organ containing several types of tissue, but only one of these types assumes malignancy, and this one alone persists malignant until the end. A tumor in the breast may start from the epithelium and form a carcinoma, or it may start in the connective tissue and form a sarcoma, but as yet no one has described a tumor of the breast that started from both structures and was a mixed "sarcocarcinoma." The carcinoma may produce secondary growths in a strictly connective-tissue structure, for example a vertebra, but the secondary growth will still, without a single known exception, be a carcinoma. If the sarcoma produces secondary growths in an epithelial organ, say the liver, the secondary growths will invariably be sarcomas. The cause of sarcoma must, then, be looked on as having a specific nature, so specific that it can not produce a carcinoma even when in a place where the epithelial elements vastly predominate; the cause of carcinoma must be equally specific.

Of such significance is this rule of growth that the question of its exceptions becomes of great importance. How often and under what conditions do primary tumors occur simultaneously in different places in the same individual, and how often do primary tumors of different natures occur in the same place at the same time, forming a tumor composed of two sorts of malignant tissue at once? Occasionally reports have been made of cases of multiple primary tumor formation in which the individual has had distinct primary growths arising in different places either at one time or at different periods of time. Usually both tumors are of the same character, and generally they are carcinomas. One of the most commonly observed of these is the formation of independent skin carcinomas on different portions of the body, particularly in the aged. Nehrkorn has even observed three such independent primary growths in different portions of the intestinal tract in which the histologic structure was so distinct as to guarantee the independence of the growth—for example, a squamous cell carcinoma of the esophagus and a cylindrical cell carcinoma of the stomach. Van Hansemann was able to collect but twenty-two cases in the literature in which patients had had a carcinoma in one part of the gastrointestinal tract and another in some other part of the body at the same time, and in none were more than two primary growths observed. In spite of their close functional relation, however, and the frequence of primary tumors in each organ, only two or three cases have been reported in which a patient suffered with carcinoma in the uterus and in the mammary gland at the same time. There are more instances of simultaneous growths in the uterus and ovaries, but the ease of extension and metastasis from one to the other makes these cases more uncertain. The same difficulty exists in the cases of apparent primary carcinoma and sarcoma of both ovaries, of which many have been reported.

The simultaneous occurrence of carcinomas and sarcomas is even less frequent, particularly if we exclude a number of the cases of such tumors in the uterus or ovaries, in which the observers have evidently been misled by the peculiar sarcoma-like character of the cells of the stroma of the ovary and submucosa of the uterus. The most valuable of these cases are those in which separate metastases of sarcoma and of carcinoma have been found, and of these there are less than half a dozen. Such a case is that reported by Grawitz, the patient being a woman of 67 years, who, in addition to several benign myomas of the uterus, had a sarcoma of the uterus and a carcinoma of the small intestine, each of which had produced metastases of its own kind in other organs.

Most interesting of all are the tumors which contain both sarcomatous and carcinomatous elements in the same primary growth. If we consider the relation of prolonged irritation to the production of malignant proliferation of cells, we might reasonably expect, from this cause alone, that the rapidly-growing, irritated and inflamed stroma of a carcinoma might take on proliferation of a malignant type. Or if we consider Cohnheim's theory that tumors arise from misplaced nests of embryonal tissue, and that most of such nests (e. g., adrenal nests in the kidney) contain both epithelial and connective tissue structures, we might expect that both types would take on malignant proliferation at the same time. In spite of both of these possibilities, however, such primary mixed tumors are among the rarest of occurrences—there are scarcely a dozen cases reported. For some unknown reason they are most frequently present in the thyroid, and hence have usually been secured as surgical specimens by operation. Perhaps on this account in but one of these cases has the final conclusive evidence of dual nature been shown; that is, the production of metastases containing both types of cells. The man who has a case of acromegaly, or of acute yellow atrophy, or carotid gland tumor, or of blastomycosis, or of any of the other important but rare diseases, and does not make the facts available to others, is committing a sin of omission.

BEHRING'S NEW REMEDY FOR TUBERCULOSIS.

The summary by Dr. Klebs, in this issue, of Behring's address at the International Congress for Tuberculosis gives us as clear an idea as at present attainable of the real gist of this matter. Shorn of bewildering detail and ambiguities, Behring's method consists in the use, for protective and curative purposes, of certain otherwise harmless constituents of the tubercle bacillus. The method appears to be a natural outgrowth of the successful immunization of cattle against bovine tuberculosis by means of injections of human and other varieties of tubercle bacilli. The introduction of living tubercle bacilli into human beings is not practicable and consequently it became necessary to try to secure the immunizing and possibly also curative substance or substances in sterile form, and this it is that Behring indicates that he believes he has succeeded in doing.

[1] Jour. of Pathol. and Bacteriol., June, 1901.

[2] Amer. Jour. Med. Sci., February, 1903.

[3] American Medicine, 1902, Aug. 30, p. 331.

In this work Behring follows paths already broken in the efforts to obtain protective and curative substances from tubercle bacilli, as well as from other bacteria. E. Klebs has maintained for years that tubercle bacilli contain a curative element. Some of the earliest successful immunizations against tuberculosis were accomplished by Trudeau, de Schweinitz and others in this country. In recent years much effort has been given also to obtain in as pure form as possible the substances of cholera, pest, typhoid and other bacteria that give rise to immunity in susceptible animals in order to develop practical methods of preventive inoculation, and considerable progress has been made in this respect.

Translated into the terms of present-day immunology, the various ideas expressed as to the mode of action of "the curative element" of the tubercle bacillus, one would say that tubercle bacilli, like pathogenic microbes in general, contain certain elements or antigens which, when introduced into suitable animals, may give rise to cellular reactions, leading to the formation of specific antibodies of various kinds and possibly to the development of a kind of cellular immunity, the nature of which we do not now understand. Concerning these antibodies little is yet actually known, but there is some reason to believe that bodies concerned in phagocytosis are of particular importance.

With the scanty information now at hand it is easier to understand the protective than the curative action of Behring's "TC" or tubercle antigens. One may conceive, however, that the injection in the infected organism, at a favorable period, of considerable quantities of antigens would stimulate and hasten the reactions that tend to natural healing, which we know occurs in a large per cent. of infected persons after a certain age. But at this juncture the advice given by Hunter to Jenner seems peculiarly applicable: "Don't think, but work!"

RATIONAL SANITATION.

In a very readable article in *Leslie's Weekly* for November 23, Surgeon J. H. White, United States Public Health and Marine-Hospital Service, who was in charge of the victorious fight against yellow fever at New Orleans, outlines the lessons of the epidemic. The chief one is in his title: "No more shotgun quarantines for yellow fever." The task faced in New Orleans this year was much more formidable than that at Havana in 1901. In the matter of sewers, water supply and dwellings New Orleans was in worse condition, while Havana had a docile population accustomed to military rule. A sane and rational quarantine admits any one from any where after six days' observation, and freely admits persons in good health who can prove that they have not been in an infected locality. Many persons from infected towns were openly admitted to New Orleans, but none of them gave rise to further cases. All that is necessary, in fact, is to know just where each entrant resides, so that surveillance can provide for prompt isolation, screening and fumigation. "A case of yellow fever known is a case of yellow fever extinguished." Dr. White thinks "that train infection is a myth." About 100 Mississippi guardsmen for sixty days traveled back and forth from New Orleans to the Alabama-Mississippi line in the same cars with New Orleans passengers, but not one guardsman was infected. He believes "that the infector, the *Stegomyia fasciata*, remains very close to the point where it receives its infection, and that for all practical purposes the disinfection of the houses themselves will result in the elimination of the infection in nine hundred and ninety-nine cases out of a thousand."

A UNITED PROFESSION IN NEW YORK.

According to a telegram received as we go to press, at a special term of the Supreme Court, held in Rochester, December 9, Judge Davy signed the order consolidating the Medical Society of the State of New York and the New York State Medical Association. This, as we understand it, removes the last technical obstruction to the uniting of the two state bodies. The members of the county societies become members of the district branches and of the state society, and thus the new body contains a membership of over 6,000. As we understand it, the new constitution and by-laws of the old state society become effective immediately, but until the county societies have elected delegates to the house of delegates to the state society the management will be carried on by the state officers and the chairmen of standing committees. Thus the movement that was started nearly four years ago has finally accomplished the object for which it was started. Since January, 1902, the committees representing the two bodies have been constantly at work arranging details and overcoming legal and other obstructions. The committees are certainly to be congratulated on the result of their work, and should have the thanks of the profession not only of New York, but of the whole country. A reunited profession will celebrate the hundredth anniversary of the organization of the Medical Society of the State of New York at the annual meeting to be held next month in Albany.

FOOD-STORAGE REFORM.

A bill which was introduced at the last session of the New York Legislature, but which failed to pass, is to be again introduced at the coming session. It provides for the prohibition of the storage of poultry or game in an undrawn condition and the sale of such to the public. Attention has been called to the many cases of toxin infection from eating game and poultry which has been stored in an undrawn state. Naturally, the bill will be resisted by powerful interests, but it ought to pass. The idea of eating fowls which have been hung up in storage for indefinite periods with decomposing viscera unremoved, is not esthetically attractive, and public opinion and requirements ought to be easily molded against such practice, even if the very evident sanitary conditions have less weight.

THE "DRUMMER" EVIL AT HOT SPRINGS.

It appears to be a fact that, in spite of the United States control of the Hot Springs reservation, the old evils there still exist. It has become one of the great health resorts of the country, but for some reason, perhaps for the lack of sufficient legislation by Congress or the state legislature, or lack of sufficient power on the part of the authorities to enforce existing enactments, the drummers and quack doctors are still in evidence and the commercialism and graft that were before notorious are still in full sway. The leasing of the privileges by the government under present regulations is held by some to be responsible for this. As far as the general government is responsible for matters at Hot Springs, it is its duty to make and to enforce such rules as will bring about a better state of affairs. If legislation by Congress is necessary it should be attended to at once. If the cession of state control is not sufficiently complete the people of Arkansas have also a duty in the matter. The continuance of the old state of affairs, as alleged, is a credit to no one.

TREATMENT OF ARTERIOSCLEROSIS.

While it can not be denied that heredity is a not unimportant factor in the development of arteriosclerosis, still it must be admitted that not less significance is to be attached to the exciting factors, namely, strain, infection and intoxication. The effects of the former are not readily averted, although something can be done in this direction, while numerous prophylactic measures may be instituted to exclude the latter. The disease of the vessels must be looked on as a response of the tissues to various irritants, and in its prevention effort must be directed to strengthening resistance and to avoidance and removal of undue stimulation. Even when developed the disorder is not wholly unamenable to therapeutic intervention. At least its effects can be ameliorated in part and its further progress retarded. Great usefulness in this direction is claimed by Dr. E. Hirschfeld[1] for the systematic employment of hot baths, from which he has obtained favorable results during a period of two and a half years. Precision in application is essential to success. The reactivity of the individual patient must first be determined. If the patient be a male not above 55 or 60 years of age, the bath may be begun at a temperature of 102 degrees. The immersion should not, as a rule, be continued for less than ten minutes. On the other hand, the treatment should not be undertaken unless the left heart be sound and the vascular pressure good. In general, though not without qualification, it may be said that the hot bath is likely to do good when digitalis is contraindicated, and conversely. The good effects of the hot bath in the treatment of arteriosclerosis are to be attributed (1) to a reduction in blood pressure by unloading the internal organs and increasing the supply of blood to the skin; (2) to increased combustion, as indicated by elevation of bodily temperature; (3) to increased elimination of waste products superinduced by the resulting perspiration.

Medical News

CALIFORNIA.

Physician Twice Fined.—Dr. Francis J. Todd, Oakland, on November 16 was fined on one count $2 and on another count $5 for exceeding the automobile speed limit.

Sent to Prison.—Dr. Herbert T. Thornburgh, San Francisco, an employé of a patent medicine manufacturer, was sentenced on November 18 to serve two and one-half years in the state penitentiary at San Quentin for forgery.

Midwife Not Guilty.—Emelie Sutler Simon, a midwife, of San Francisco, charged with causing the death of Mrs. Angela Venezia by a criminal operation, was discharged November 11, the judge stating that he found no proof of guilt.

Inmates in State Institutions.—The State Board of Charities reports the following number of inmates in the various institutions of the state: State Hospital at Stockton, 1,099; at Napa, 1,491; at Agnews, 1,063; at Mendocino, 667; and in southern California, 833.

October Vital Statistics.—Reports from 53 of the 57 counties in the state show 1,873 births, equivalent to an annual rate of 13.1 per 1,000; 2,117 deaths, equivalent to an annual rate of 14.9 per 1,000; and 1,464 marriages. Tuberculosis led the death causes, with 299, followed by heart disease with 184, pneumonia with 127, injuries (including suicide) with 127, cancer with 119, diarrhea with 112 and Bright's disease with 106 deaths.

Hospital News.—Mrs. Millicent Olmstead, San Gabriel, has executed a deed setting aside a residence and business property in Los Angeles and a ranch in Elmonte, to be sold after her death and the proceeds devoted to the establishment and maintenance of a free hospital. The property deeded is valued at more than $200,000.——The Oceano Outdoor Sanatorium for Consumptives, Santa Monica, netted $1,374.89 from the garden fête recently given by Miss Georgiana Jones at Miramar.——The new detention hospital for Los Angeles at Chavez Revine will be completed in about three months.——Pasadena Hospital is to have a handsome addition 124x75 feet, to cost about $30,000, accommodating 30 patients and given by O. S. A. Sprague as a memorial to his late wife.

COLORADO.

New Hospital.—A new hospital is to be erected at Boulder Hot Springs at a cost of $9,000.—A non-sectarian hospital, under the auspices of the Colorado Conference of Deaconesses, will be erected in Colorado Springs at an expense of $100,000.

Additions to Sanatorium.—The new St. Anthony addition to the Glockner Sanatorium, Colorado Springs, has been erected and equipped at a cost of about $40,000, and 29 tents or cottages have been located on the grounds of the institution, at a cost of about $23,000.

The Old Trick.—Forty well-to-do farmers of Weld and Morgan counties are protesting against the payment of promissory notes of $42 each, which they gave to an itinerant alleged physician a year ago on the condition that they should be cured of rheumatism. As none of the victims received benefit they naturally object to paying the notes.

CONNECTICUT.

Hospital News.—The by-laws of Norwalk Hospital have been so amended as to increase the maximum hospital staff from eight to ten.——Dr. Kenneth E. Kellogg, a member of the consulting staff of New Britain Hospital, has been placed on the attending staff and Dr. Katherine H. Travis has been appointed pathologist and bacteriologist, and Dr. Roger M. Griswold, Berlin, consulting physician.——The Danbury Hospital Association has filed articles of incorporation.——The cornerstone of St. Francis Hospital, Hartford, was laid with appropriate ceremonies October 29.

DISTRICT OF COLUMBIA.

Hospital Plans Approved.—The plans for the United States Army General Hospital, Washington, have been approved by the Secretary of War and the committee in charge, consisting of Majors Borden, McCaw and Stevens. Congress has appropriated $300,000 to complete the building.

Health Report.—The report of the health officer for the week ended December 2 shows that 101 deaths occurred and 114 births. At the close of the week the following cases of contagious diseases were under treatment: Diphtheria, 89; scarlet fever, 20; typhoid fever, 140, and smallpox, 5. The health department is investigating a number of the sources of milk supply to determine, if possible, the source of infection.

---

[1] Australasian Med. Gaz., vol. xxiv, No. 7, p. 319.

Inspection of Government Buildings and Offices.—An order has been issued for the President creating a commission consisting of Surgeon-general Robert M. O'Reilly, U. S. Army; Surgeon-general Presley M. Rixey, U. S. Navy, and Surgeon-general Walter Wyman, U. S. P. H. and M.-H. Service, to prepare and submit to the President for approval a plan for instituting an inquiry through the proper officers of the government as to the sanitary conditions existing in all government offices and workshops where a large number of persons are employed, especially with a view of recommending, if necessary, measures for prevention of tuberculosis therein, and furthermore, to detail one or more persons from each of the public services named, to assist in the formation of a plan for investigation and action.

ILLINOIS.

Diphtheria.—Owing to the prevalence of diphtheria the schools at Metcalf have been closed.——Shelbyville schools are closed on account of diphtheria.——The village of Washburn, Woodford County, is under quarantine and schools have been closed on account of the prevalence of diphtheria.

Oak Park Hospital.—At a meeting of the Oak Park Business Men's Association, December 8, Dr. John W. Tope announced that he had purchased a site for a hospital and that the Sisters of Misericordia of Montreal would build a hospital on this site next year. He declined, however, to give the location of the hospital site.

Civil Service Board.—The civil service commission has selected Drs. Hugh T. Patrick, Frank Billings, John B. Murphy and Harold N. Moyer, Chicago, and Dr. Frank P. Norbury, Jacksonville, as a board to prepare the questions and grade the papers in examinations for assistant physicians in the state hospitals for the insane.

Northern Illinois Physicians Meet.—The North Central Illinois Medical Association held its thirty-second annual meeting in Streator, December 4. The following officers were elected: President, Dr. James J. Pearson, Pontiac; vice-presidents, Drs. Edgar P. Cook, Mendota, and Edward S. Murphy, Dixon; secretary and treasurer, Dr. George A. Dicus, Streator, and censors, Drs. Franklin A. Turner, Sandwich; John M. Kaiser, Somonauk; James A. Marshall, Pontiac; Roy Sexton, Streator, and Joseph I. Knoblauch, Metamora.

Personal.—Dr. David W. Magee, Peoria, fell November 24, sustaining a compound fracture of the left hip.——Dr. Lemuel Tibbets, Rockford, will move to California after the holidays.——Dr. John B. Miller, Gilson, has decided to move to New Mexico.——Dr. James C. Stewart, Anna, has been appointed local surgeon for the Illinois Central Railroad, vice Dr. Samuel Dodds, removed.——Dr. and Mrs. George F. Heidemann, Elmhurst, have gone to Alabama for the winter.——Drs. Robert J. Christie, Jr., and Otis Johnston, Quincy, have been appointed local surgeons for the Burlington System.——Dr. Frank H. Lord, Plano, has gone to New Mexico.

Itinerant Vendor Brings Suit.—James Ferdon, an itinerant vendor of medicines, who advertises himself as "Brother Paul," and who has already been noticed in The Journal, has brought suit in Cook County against the State Board of Health to recover $100 held by the board. Ferdon made application for an itinerant vendor's license and tendered the fee of $100, which was accepted by the secretary of the board. The application was referred to the board and declined. In the meantime "Brother Paul" began operations in Freeport, using the receipt of the State Board of Health as his evidence of authority. Suit was brought against him by the board and fines of $1,800 and costs found against him. Ferdon left the state and went to Iowa where, on information given by the Illinois board, action was taken against him by the Iowa Board of Medical Examiners. Ferdon now brings action to recover the fee of $100, which the State Board of Health holds as a partial offset of the fines assessed against him.

Litigation in Enforcement of Medical Practice Act.—E. M. Harrison, who holds a diploma issued in 1903 by the now defunct Dunham Medical College, has begun action against the State Board of Health in the Circuit Court of Cook County, to compel the board to issue him a certificate without examination. The action is based on section 2 of the Medical Practice act, which provides that the board may issue certificates to graduates of Illinois medical colleges in good standing without examination. The attorney-general in 1899 held that "may" in this instance must be construed as "shall." On December 12 Judge Chytraus denied the writ of mandamus and held that it is discretionary with the board whether certificates be issued under this provision.——Several years ago the State Board of Health brought suit against Dr. Peter R. Langdon, who had practiced in Kankakee for many years, but who holds no certificate from the state board. Dr. Langdon contended in his defense that the law does not apply to him, inasmuch as the law states that "no person shall hereafter begin the practice of medicine, etc.," while he contends that he did not begin practice after the passage of the law. He was sustained in this position by the Circuit Court of Kankakee County and, on appeal by the State Board of Health, the Appellate Court affirmed the decision of the lower court. This case is now pending in the Supreme Court, and the board is hopeful that the decision of the Appellate Court will be reversed.

Chicago.

Head Eligible List.—Of the 68 applicants who took the examination for the civil service examination for medical inspectors in the health department, Dr. Edward W. Quick received the highest mark; Dr. Paul F. Morf was second; Dr. Joseph T. Friedman, third, and Dr. Kellogg Speed, fourth.

A Patient's Ingratitude.—In the case of Abraham Bernstein, who sued Dr. George F. Suker for $10,000, alleging that he had been made blind through on operation performed by the defendant two years ago, the court instructed the jury that there was no case against Dr. Suker who, the evidence showed, had treated the plaintiff gratuitously for two years as a result of which the man's sight had slightly improved.

Personal.—Dr. Maurice M. Doty has been appointed traction expert, which includes the duty of enforcing the ordinances tending to ensure satisfactory street car service.——Dr. Edwin Janss reached Los Angeles after a trip around the world.——Dr. Alonzo M. Wheeler has been elected president of the Chicago Association of Kalamazoo College Alumni.——Dr. Garrett J. Hagens met with a serious accident in a runaway three weeks ago in which his right hip was injured. He is now able to be about.

Deaths of the Week.—Although there were 71 deaths more reported for the week ended December 9 than for the previous week, and 42 more than for the corresponding week of last year, the health conditions are considered fairly satisfactory. The 554 deaths reported are equivalent to an annual death rate of 14.50 per 1,000, and this is nearly 4 per cent. lower than the average December rate of the previous decade. The increases in the chief causes of death are: Bright's disease, 11; tuberculosis, 12; heart diseases, 7; pneumonia, 21, and violence, 20. The number of deaths from these causes was as follows: Pneumonia, 83; consumption, 79; Bright's disease, 51; heart diseases and violence, including suicide, each 47.

INDIANA.

Sick and Afflicted.—Dr. John C. F. Thorne, Kokomo, was committed to a private sanatorium at Kenilworth, Ill., November 29.——Dr. Christopher C. Cronkhite, Marion, has entered a sanatorium at Hartford City to take treatment for the drug habit.

Laboratory of Hygiene Opened.—The State Board of Health announces that the State Laboratory of Hygiene, Indianapolis, is now open and ready to serve the public without cost. The department has two divisions—one of bacteriology and one of chemistry. On application physicians are supplied with outfits for the culture of diphtheria and for collecting sputum and blood for examination.

Personal.—Drs. Edmund D. Clark, Thomas B. Noble and Frank A. Morrison have been selected as a board of health for Indianapolis.——Dr. Morton J. Compton, Evansville, has been appointed secretary of the Vanderburg County Board of Health, vice Dr. Willis S. Pritchett.——Dr. John M. Fouts, Centerville, has been reappointed physician for the Wayne County Infirmary, and Dr. George H. Grant, Richmond, secretary of the Wayne County Board of Health.

Allen County Society.—At the annual meeting of this society resolutions were adopted approving the Council on Pharmacy and Chemistry, which appear elsewhere in this issue of The Journal. The following officers were elected: President, Dr. Maurice I. Rosenthal; vice-president, Dr. Eric A. Crull; secretary, Dr. J. Clifford Wallace; treasurer, Dr. William P. Whery, and censor, Dr. Samuel H. Havice, all of Fort Wayne. The society now has a membership of 84.

LOUISIANA.

Children's Sanatorium.—A sanatorium exclusively for children is to be located at 850 Carondolet Street, New Orleans, to be presided over by Dr. Erastus D. Fenner, lecturer on diseases of children in the medical department of Tulane University.

Want School of Tropical Medicine.—The administrators of Tulane University have asked the faculty of the medical department of that institution for an expression of opinion regarding the establishment of a school of tropical medicine in connection therewith.

Colored Medical Association.—At a meeting of the colored [illegible] of Louisiana at Alexandria, November 15, a state [illegible] was organized, with the following officers: Dr. Green A. Cain, Shreveport, president; Dr. L. M. Coleman, Lake Charles, vice-president; Dr. Isaac W. Young, Alexandria, secretary, and Dr. James P. Jones, Alexandria, treasurer.

A Yellow Fever Martyr.—Garnett Barnette, a medical student of Bonami, who, when the outbreak of yellow fever occurred, offered his services to the State Board of Health, and who worked hard in Bonami in the effort to stay the ravages of the disease, died from yellow fever October 20, after an illness of eight days, aged 28. Young Barnette was a brilliant student and a young man of fine promise, and in his death exemplified the love than which none is greater, "that a man lay down his life for his friends."

MARYLAND.

Deaths.—The deaths in Baltimore last week were 201, as compared with 214 for the corresponding weeks the last two years.

Left Large Estate.—The late Dr. Charles Carroll Shippen, Baltimore, who died November 6, left a personal estate appraised at $140,488.

Seat May be Contested.—The seat of Dr. Richard S. Hill, Upper Marlboro, Prince Georges County, who was announced to have been elected to the House of Delegates by 65 majority, will be contested.

Inducements of Naval Medical Service.—Medical Director R. A. Marmion, United States Navy, delivered an address in Anatomical Hall, Baltimore, December 9, on "Inducements which the Naval Medical Service Offers to Capable Medical Men."

Bequests.—The late Mr. William Ferguson, Baltimore, by will, left residuary bequests of $5,000 to the Presbyterian Eye, Ear and Throat Hospital to aid aged mechanics or members of their families unable to pay, and $10,000 to the Hospital for Consumptives for the benefit of impecunious consumptive mechanics.

City Society Meeting.—The Baltimore City Medical Society, the city branch of the Medical and Chirurgical Faculty of Maryland, held its annual meeting December 6. Dr. W. S. Thayer was elected president, and Dr. W. Edward Magruder was re-elected secretary. A resolution was adopted endorsing the Anti-Smoke League movement.

MASSACHUSETTS.

Fire at Hospital.—A fire at the Springfield Hospital November 21 damaged an old building and a laundry annex to the extent of $3,000, fully covered by insurance.

Centennial of Society.—The Essex South District Medical Society held its centennial anniversary in Salem November 21. The papers read were chiefly of an historical nature, dealing with the early days of the society and its early members.

Bequests.—By the will of Samuel Ivers of New Bedford, $500 is left to St. Luke's Hospital, $250 to the Instructive District Nursing Association, $500 to the North Day Nursery, $500 to the South Day Nursery, besides similar amounts to many other charities.

Poison in Lunch.—Dr. Herbert J. Keenan, chairman of the committee on mechanic arts, High School, Boston, from which most of the cases of ptomain or formaldehyd poisoning have been reported, has made a careful study of the cases of illness which originated in that school, and declares that in almost every case the symptoms were those of formaldehyd poisoning.

New Boat for Floating Hospital.—The board of managers of the Boston Floating Hospital have decided to build a new boat. It is to be 170 feet long and 46 feet wide, with wards to contain not more than 16 sick babies each. Accommodations will thus be provided for 100 patients, besides another 150 who can be taken out on the upper deck for the day. This will practically double the capacity of the hospital, which for several years now has turned away, for lack of room, nearly or quite as many as have been admitted. The cost of the new boat will be about $60,000, and earnest efforts are being made to raise this entire amount.

Personal.—Dr. Arthur G. Minshall is in charge of the medical department of the Dickinson Hospital, Northampton, for the coming quarter; Dr. Alfred H. Hoadley of the surgical department; Dr. Clarence R. Gardner of the eye and ear department, and Dr. Justus G. Hanson of the pathologic department.——Bert R. Rickards has been appointed head bacteriologist of the Boston Board of Health.——Dr. Clarence P. Curley, Provincetown, has been appointed medical examiner for the third Barnstable district, vice Dr. Samuel T. Davis, Orleans.——Dr. Philip Kilroy has been appointed dermatologist and neurologist on the staff of the Springfield Hospital.——Dr. Frank D. Stafford, North Adams, who has been seriously ill with septicemia due to an operation wound, is improving.——Dr. George L. Perry, Athol, has been elected a member of the board of health, vice Dr. Garrett B. B. Larkeque, resigned.——Dr. C. E. Street has been made a member of the staff of the Isolation Hospital, Springfield, vice Dr. T. S. Bacon, resigned.——Dr. Percy C. Procter, Gloucester, retired from practice December 1 and was succeeded by Dr. Philip F. Moore.——Dr. and Mrs. Albert C. Cobb, Marion, arrived in New York November 27 from Vienna.——Dr. Edward O. Otis, Boston, has been appointed visiting physician at the State Sanatorium for Tuberculous Patients, Rutland, vice Dr. Vincent Y. Bowditch, Boston.——Dr. Robert W. Lovett has been elected attending surgeon and Dr. Henry R. Hitchcock attending physician of the New England Peabody Home for Crippled Children.——Dr. Timothy J. Reardon, for several years assistant laryngologist at Carney Hospital, Boston, has been appointed trustee of the Boston City Hospital, replacing Henry H. Sprague.

MICHIGAN.

Smallpox.—Four cases of smallpox are reported at Hudson's logging camp near Menominee.

Money for Hospital.—The bazaar at Kalamazoo for the benefit of Borgess Hospital netted about $6,000 for the institution.

Personal.—Dr. William J. Stapleton has been appointed physician of Wayne County to succeed Dr. S. L. Polozker, resigned.——Dr. John E. Clark has been appointed chemist and Dr. E. B. Forbes, a physician of Wayne County.

Physician Gets Damages.—Dr. Eugene Smith, Detroit, was awarded $1,500 damages in the United States Court at Trenton, N. J., November 29, for injuries received by being thrown from a berth on board the steamer *Vaderland*, belonging to the International Mercantile Marine Company.

Women's Efforts Erect Hospital.—The new $40,000 hospital building erected at the Michigan Insane Asylum, Kalamazoo, at a cost of $40,000, was formally dedicated November 5. This building is the result of three years' earnest work by the women of Kalamazoo, who formed a women's auxiliary for this purpose. The building is fireproof, four stories in height, thoroughly equipped and will accommodate 50 patients.

MINNESOTA.

Personal.—Dr. and Mrs. C. M. Kistler, Minneapolis, have gone to Europe.

An Unhealthy November.—November was an unhealthy month at Minneapolis. More than 30 deaths were caused by pneumonia and typhoid fever, and the deaths from all causes numbered 225, equivalent to an annual rate of 10.3 per 1,000.

Lift Debt of Hospital.—Messrs. D. C. and F. B. Shepherd, St. Peter, gave $35,000 at a thanksgiving offering to St. Luke's Hospital Association to pay the mortgage indebtedness of that institution. The gift is made in memory of Mrs. D. C. Shepherd, who died three years ago.

Minnesota Valley Physicians Meet.—At the twenty-sixth annual meeting of the Minnesota Valley Medical Association, held in Mankato December 5, resolutions of condolence were adopted on the death of the late secretary, Dr. Edwin D. Steel, Mankato. The following officers were elected: Dr. Michael Sullivan, Adrian, president; Drs. George R. Curran, Mankato, and Fred P. Strathern, St. Peter, vice-presidents; Dr. Adolph G. Leidloff, Mankato, secretary, and Dr. George F. Merritt, St. Peter, treasurer.

Hospital News.—The George B. Wright Memorial Hospital, Fergus Falls, was opened for patients November 15. The board of trustees of the City and County Hospital Association of Albert Lea has leased the hospital property of Dr. Hamilton H. Wilcox in that city and the building will be converted into a general hospital.——The committee on streets has ordered an unfavorable report on the application of Miss Helen G. Hill for a license to operate a hospital for crippled children in St. Paul.

MISSOURI.

Taken to State Hospital.—Dr. James T. Johnson, Shell City, has been committed to the State Hospital for the Insane No. 3, Nevada.

Hospital Sunday.—It is estimated that the receipts from the Hospital Saturday and Sunday Association, St. Louis, December 2 and 3, will reach $35,000.

Examination of School Children.—The medical examination of children in the Kansas City public schools was inaugurated November 20 by a corps of 50 medical inspectors.

Personal.—Dr. Charles A. Snodgrass, acting health commissioner since the removal of Dr. John H. Simon in July last, was formally elected health officer of St. Louis, November 17. ——Dr. A. J. Detweiler, Columbia, has resigned as bacteriologist of the State Board of Health and expects to locate in Hannibal.——Dr. and Mrs. Joseph W. Howard, Kansas City, have returned from a visit to the East.

MONTANA.

New Hospital.—It is announced that John Manning will soon erect a hospital building to cost $9,000 at Boulder Hot Springs.

Diphtheria.—There are no new diphtheria cases reported in Anaconda, and only about 20 cases have been reported since the disease made its appearance in the city a few weeks ago. Strict quarantine and disinfection have been observed.

Personal.—Dr. George H. Putney, Missoula, has received an appointment from the Panama commission and has left for his post of duty at Colon.——Dr. Gowan Ferguson, Great Falls, was operated on for abscess of the liver at Rochester, Minn., recently.

Physician Loses Suit.—In the case of William Barbour vs. Dr. James L. Jones, Dillon, for $300 damages alleged to have been suffered by reason of the loss of his wife's services for six months caused by her inability to attend to household duties, the jury returned a verdict in favor of the plaintiff for $50.

NEBRASKA.

Hospital Rebuilt.—The work of reconstruction of the old west wing at the Nebraska State Hospital, Norfolk, into a cottage for the accommodation of more patients has commenced, and the work will be completed early in the summer. The new cottage will cost about $21,000 and will accommodate 50 patients.

Personal.—Dr. Emma C. Robbins, third assistant physician at the Hastings State Asylum, has resigned.——Dr. Robley C. Harris, Sidney, has resigned as receiver of the United States Land Office.——Dr. and Mrs. J. C. Agee, Valley, have moved to Nevada.——Dr. G. W. Strough, Barneston, has been appointed division surgeon of the Union Pacific Railroad.——Dr. Philip H. Metz, Humphrey, has been appointed district surgeon and physician for the Union Pacific Railroad.

Diphtheria.—The South Ward school, Aurora, was closed recently and fumigated on account of diphtheria.——Dr. H. Winnett Orr, Lincoln, who has studied the progress of diphtheria in that city and the use of quarantine methods and antitoxin, asserts that the use of antitoxin has reduced the death rate from 40 per cent. to 2 per cent. or less. He estimates the total number of cases during the fall months at 150 and states that 33 cases were quarantined during October.——In Benson 12 cases have been reported and the public schools have been closed.——The board of health and school board of Beatrice have decided to close the South school for fumigation on account of diphtheria.

NEW HAMPSHIRE.

Epidemic of Scabies.—An epidemic of what is called the old-fashioned "army itch" is prevalent in Nashua. It is estimated that there are 500 cases in the city.

Hospital Notes.—The Elliot Hospital, Manchester, is to receive $5,000 by the will of Mrs. Angeline B. Cilley to support a free bed.——It is suggested that the new hospital now in process of construction in Exeter, to cost $25,000, be named after Edward Tuck of Paris, who gave $11,000 toward the building fund.

Oppose Contract Medicine.—The Nashua Medical Association on November 27 voted unanimously to stand by the resolution passed some time ago against contract medicine. By the terms of this resolution the members of the association agree not to enter into contracts with lodges, societies, organizations or corporations.

Personal.—Dr. George Cook, Concord, president of the Alpha-Kappa-Kappa fraternity, was given a banquet at Nashville, Tenn., October 26.——Dr. Frank W. Grafton has been elected president of the Concord District Nursing Association.——Dr. Napoleon Matte, Keene, fell while leaving the house of a patient and fractured a bone in the left foot.

NEW JERSEY.

Charitable Bequest.—By the adjudication of the estate of the late Maria T. Wirgman the Cooper Hospital, Camden, receives $24,689.50.

New Hospital.—Mayor Fagan, Jersey City, who broke ground for the new City Hospital September 8, laid the cornerstone of the institution November 1.

Diphtheria.—Diphtheria has again broken out in Millville and it is feared that the schools will have to be closed.——One school in Cranford has been closed on account of diphtheria.

Personal.—Dr. Sylvan G. Bushey, Camden, sustained severe contusions in a fall from a trolley car November 18.——Dr. Joseph B. Shaw, Trenton, has returned after six months' stay in Germany.——Dr. Wiliam H. Kensinger, Camden, has been elected a member of the city council.

NEW MEXICO.

Personal.—Dr. William J. Hammer, who has been for the past five years first assistant physician at the Loomis Sanitarium, Liberty, N. Y., has been appointed resident medical director at St. Joseph's Sanatorium, Silver City. He will assume the duties of his new position at once.——Dr. Carl Hagen, Silver City, has returned after an absence of four months in Europe.

Albuquerque Protests Against Influx of Incurables.—At a meeting of the associated charities of Albuquerque, November 2, the following resolution was adopted:

> *Resolved,* That the physicians and authorities in other sections be strongly censured for sending health seekers to Albuquerque and New Mexico when they have reached the stage where they are beyond help from climatical advantages or are without sufficient funds to support themselves for a period of at least six months, and that the press be urgently requested to give this resolution the greatest publicity.

NEW YORK.

Hospital Incorporated.—The certificate of incorporation of the City Hospital for Women, Buffalo, has been issued. The concern is capitalized at $1,000.

Bequests.—By the will of the late Dr. DeVille W. Harrington, Buffalo, $3,000 is added to the $2,000 heretofore given for the endowment of the Dr. Harrington lectureship. About $125,000 was also left to the Buffalo General Hospital to endow the Dr. Harrington Hospital for Children.

Gift to Infirmary.—The Ballston Infirmary, situated at Spa, has been presented with $5,000 in 4 per cent. railroad bonds by Harriet N. Carpenter. The interest from these bonds is to be used for the support of this institution, which was presented to the county about three years ago by Horace W. Carpenter of New York City.

State Charity Work.—The third annual meeting of the State Charities Aid Association was held in the United Charities Building, New York City, December 6. George F. Canfield, president of the association, in his report as chairman of the committee on the insane, said that there was a decrease in the number of new cases this year, as compared with last year, and that the increase in the number of committed insane during the year was less than in any year since 1890, the total number being 547, as compared with 927 last year, and an average of 758 a year for the past ten years. The total number of committed insane in state hospitals and private asylums on October 1 was 27,408, of whom all except 985 were in state hospitals. The legislature of last year made provision for increased accommodations at the Institution for the Feeble-minded and Epileptic. The Craig Colony for Epileptics was allowed a new building for 200 inmates; the Newark State Custodial Asylum for Women, two cottages, each for 60 inmates, and the Rome State Custodial Asylum, a dormitory building for 100 inmates, and sufficient money to purchase 150 acres of farm land. Dr. Charles Hitchcock was re-elected as one of the members of the board of managers.

New York City.

Tuberculosis Exhibition Moves.—This exhibition, which has been open for two weeks at the American Museum of Natural History, will be moved to Boston, to Philadelphia, and to other larger cities.

Low Death Rate.—The death rate figures for the week ending December 2 were 17.82 per 1,000. This is unusually low for this season of the year. The only increase in mortality was from measles.

Personal.—Dr. George Montgomery Tuttle sailed for Genoa on the *Cretic* December 7.——Dr. Armand L. F. Dufloo was assaulted and robbed while returning from a night call. He lost $70 in money, a gold watch and some valuable papers.

Long Island Open-air Sanitarium.—The trustees of this institution have appealed for funds. The institution will be for the use of Brooklyn and Long Island. In Brooklyn alone it is estimated that there are more than 10,000 consumptives, most of whom are unable to provide proper treatment. The estimated cost of land, building and equipment is $50,000. It is hoped that it will be self-supporting.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended December 2, 421 cases of tuberculosis, with 174 deaths; 438 cases of measles, with 11 deaths; 285 cases of diphtheria, with 34 deaths; 157 cases of scarlet fever, with 6 deaths; 71 cases of typhoid, with 10 deaths; 15 cases of cerebrospinal meningitis, with 15 deaths; 154 cases of varicella and 1 case of smallpox.

Hospital Anniversary.—The thirty-seventh anniversary of the Presbyterian Hospital has just been celebrated. The annual report shows that during the fiscal year ended September 30 last, 47,933 patients were treated in all departments, an average of 606 per day. This was 13 per cent. more than were cared for during the previous year. Only a very small proportion were able to pay the actual cost of their care. The receipts from donations were $60,439, compared with $42,059 for the previous year. The receipts from legacies were $187,249. The actual cost to the hospital for free treatment during the year was $168,814, and the cost per day per patient was $2.81.

Work of the City Hospitals.—The report of the trustees of Bellevue Hospital and Allied Institutions for the first quarter of this year has been made public. The four hospitals under the management of the trustees admitted 9,173 patients, of whom 6,179 were men and 2,994 were women. Of these patients 4,022 were natives of the United States, 1,854 were born in Ireland, 699 were of Russian birth, and 686 were Germans. Bellevue received 7,210 of these patients; Gouverneur admitted 1,073, of whom more than one-third were Russians; Harlem Hospital admittea 621, and Fordham 269. In the out-patient department of Bellevue 5,581 new cases were treated, there being a total of 18,875 visits and 22,155 prescriptions. Gouverneur had 6,306 new patients, 15,450 visits and 11,930 prescriptions. Harlem's record was 6,591 new patients, 15,450 visits and 15,858 prescriptions, while the figures for Fordham were 659 new patients, 1,395 visits and 1,494 prescriptions. In the psychopathic wards of Bellevue 642 patients were received, of whom 340 were men and 302 women. The record for acute alcoholism shows 7 women and 6 men.

Reform in Hospitals.—A movement to put the hospitals of this city on a business basis, to bring about co-operation, to curtail expenses, and thus greatly to enlarge their powers of usefulness, was inaugurated in March of this year by the Society for the Improvement of the Condition of the Poor. An association of hospital superintendents has been formed, the first of its kind in the city, and at the next meeting it will discuss a list of rules that has been drawn up for the purpose of preventing the waste of hospital supplies. It is claimed that if all the hospitals would *co-operate in the matter of business* management, $1,000,000 could be saved annually. Among the questions to be discussed are: What plan is best fitted to increase the financial support, individually or jointly? What opportunities are there for decreasing hospital expense? Is a uniform method of accounting desirable among the several hospitals? The sub-committee on economy suggests several means of lessening expense. For example, the use of ether of a cheaper grade, but just as safe; the closed method of inhalation of ether; dressings and bandages to be washed, resterilized and used over in some cases. Much saving can be effected in the use of alcohol. Coal and other commodities could be purchased in cargo by co-operation of several hospitals. There should be one executive officer in an institution who would have authority to enforce the methods to secure a minimum of expenditure. Methods which are demonstrated to have the advantage of simplicity and economy in certain institutions should be adopted in others.

NEVADA.

Damage by Fire.—The offices of Drs. Dunham and Wedelstaedt, Goldfield, were damaged to the extent of $2,500 by fire, November 7.

Census Shows No Hospital.—Nevada is not credited with possessing a single hospital in the special census bureau report on benevolent institutions of the United States for 1904.

Must Have License.—The Supreme Court of the state has upheld the act requiring physicians to take out licenses before they can practice. The case came up on appeal from Nye County, where Dr. Wyerhoist was fined for violation of law and appealed.

Paupers Declared Insane.—Dr. Samuel C. Gibson, superintendent of the Nevada Hospital for Mental Diseases, Reno, makes the charge that many counties of the state, in order to rid themselves of the care of the pauper sick, are declaring these unfortunates to be insane and committing them to the state asylum.

State Board of Health.—The new State Board of Health assembled for organization at Carson City, October 27. The new appointees, Drs. Simeon L. Lee and Berry of Carson City, and Dr. Samuel C. Gibson, Reno, were sworn in. Dr. Berry was elected president; Dr. Gibson, vice-president, and Dr. Lee, secretary. Dr. Gibson was also appointed health officer of Washoe County.

OHIO.

Hospital Staff Reappointed.—The entire staff of the City and Branch hospitals, Cincinnati, was reappointed December 4.

Physicians Ill.—Dr. I. A. Myers, Shelby, is seriously ill with heart disease.——Dr. L. M. Brumbaugh, Dayton, who has been ill with typhoid fever in Salt Lake City, is reported to be improving.——Dr. James B. King, Wyoming, is seriously ill with erysipelas at his home.

New State Hospital Site.—It is stated on reliable authority that the new State Hospital for Tuberculosis will be located about two miles east of Zanesville, on a tract of about 450 acres. The main building will be situated on a hill 1,500 feet above sea level. The land itself will cost about $30,000.

Hospital Opened.—The Memorial Hospital, presented to the city of Piqua by Mrs. Julia Ball Thayer of Keene, N. H., in memory of her brother, the late D. L. C. Ball, is completed, and a short dedicatory service was held November 30. On December 7 the hospital was opened with appropriate ceremonies.

Hirst in Cincinnati.—Dr. Barton Cook Hirst, Philadelphia, addressed the Cincinnati Academy of Medicine December 11 on "The Diagnosis and Treatment of Puerperal Infection." During his stay in Cincinnati Dr. Hirst was the guest of Dr. Magnus A. Tate, and on the afternoon of December 11 Dr. Tate gave a reception.

Epileptics Incurable.—In the annual report of the superintendent of the State Hospital for Epileptics in Gallipolis, he says: "Our experiments more and more confirm the opinion that true epilepsy is essentially incurable." During the history of the institution only six persons have been discharged as recovered. The trustees ask $196,000 for current expenses for the next two years and $129,750 for new buildings, land and other objects.

Liquor License for Patent Medicines.—The internal revenue commissioner has stated that the special stamp tax stamp of retail liquor dealers taken out by any person for the sale of alcoholic compounds labeled as medicines must be issued to him for a fixed place of business and that he can not travel from place to place, selling such compounds in the manner of a peddler and be protected by any special tax stamp. He further says that the revenue laws do not contemplate the peddling of alcoholic liquors, and every person found doing business in that manner becomes involved in a special tax liability at every distinct and separate place at which there is evidence of his having made such sales.

Personal.—Dr. Frank B. Cross, Cincinnati, has arrived in London.——Dr. Edgar Dimond, Cincinnati, sailed for Europe December 9 for a year's study in Vienna.——Dr. Albert F. McVety has been appointed head of the medical department of the Y. M. C. A. of Toledo.——Dr. H. C. Rutter, formerly superintendent of the State Hospital for Epileptics, Gallipolis, has accepted the medical directorship of the department of nervous and mental diseases of the Ohio Sanatorium Company, operating the sanatorium in Columbus and also one in Marion. Dr. Mark A. Brown, editor of the *Lancet-Clinic*, Cincinnati, has had a severe sprain of the ankle.——Dr. Oliver P. Holt is convalescing from appendicitis.——Dr. George Holt has just finished his term of service as resident physician to Christ's Hospital, *Cincinnati*.

State Association of Medical Teachers.—A meeting has been called to organize a state association of medical teachers at the Great Southern Hotel, Columbus, December 26, at 2 o'clock. The program, which is already prepared, takes up the following subjects: "The Advantages and Purposes of an Organization of the Medical College Teachers of the State," "The Medical College Curriculum—the First Two Years," "The Medical College Curriculum—the Last Two Years," "The Relation of the *Literary and* Medical College," "Should Advanced Standing as Regards Medical Residence be Given to Graduates of Literary Colleges, or Should Four Years of Medical Residence be Invariably Required?" "What Subjects and How Much Work in Each Should be Required of a Graduate of a Literary College to Gain a Year's Advanced Standing in the Medical Colleges of This State?" "The Cultural Value of the Fundamental Medical Studies," "What Medical Subjects Can be and What Can Not be Properly and Efficiently Taught in the Literary College," "What Science Work Will be Held by the Board as Satisfying the Requirements of This Resolution? Will the Board Issue Certificates to Students Whose Literary Course Fulfills This Requirement?" and "The Administrative Side of the Question from the Standpoint of the Literary College."

Second District Society Meets.—The second annual meeting of the Second District Medical Society was held in Dayton, November 21. After the transaction of routine business, resolutions were passed urging the incoming governor to appoint medical men on the various boards, who should be as nonpartisan as possible, that the medical profession rather than the politicians might be consulted in matters of state, and that the appointments might be based on personal integrity, professional learning and scientific attainment rather than on political influence. The society also adopted the following resolutions:

Resolved, That the Second Councilor District of the Ohio State Medical Association do hereby heartily endorse the series of articles now being published in *Collier's Weekly* under the title, "The Great American Fraud," exposing the machinations and conspiracies of the patent medicine curse.

Resolved, That we urge on the representatives of the various county societies of this district the advisability of presenting the matter before their respective societies and of devising some active and systematic method of calling the attention of the people, especially that great mass of people who are not reached by a paper like *Collier's*, to this remarkable series of articles and that especial efforts be made to secure the co-operation of the clergy, school teachers, college professors and every person who in any way has to do with public instruction in this campaign against these human vultures, the patent medicine vendors.

The election of officers resulted as follows: President, Dr. John M. Buckingham, Springfield; secretary, Dr. Daniel B. Conklin, Dayton, and treasurer, Dr. Charles L. Minor, Springfield. It was decided to hold the next meeting at Springfield.

PENNSYLVANIA.

Communicable Disease in the State.—During the month of November there were reported to the State Department of Health 4,508 cases of communicable diseases. Many cases were reported from the rural districts on cards provided for this purpose by the department of health.

Bucks County Society Election.—At the meeting of the Bucks County Medical Society, November 1, the following officers were elected for the ensuing year: President, Dr. Richard C. Foulke, New Hope; vice-presidents, Drs. Howard Pursell, Bristol, and Julius T. Vissell, Perkasie; secretary-treasurer and reporter, Dr. Anthony F. Myers, Blooming Glen; censors, Drs. George M. Grim, Ottsville; Alfred E. Fretz, Sellersville, and William R. Cooper, Point Pleasant.

Convicted of Abortion.—Mrs. Minnie Yochim-Salow, Erie, convicted of abortion and manslaughter on November 25, was sentenced to pay a fine of $50 and the costs of prosecution and to undergo imprisonment by separate or solitary confinement at labor in the Western Penitentiary for a period of three years. In the manslaughter case she was sentenced to pay a fine of $100, the costs of prosecution and to undergo imprisonment in the Western Penitentiary by separate or solitary confinement at labor for a period of six years. Judge Walling concluded the penalty by remarking that "abortion can not be tolerated in any form by this court; it is next to murder, and often results in murder."

Vaccination.—Since the State Department of Health was established in May last by the appointment of Commissioner Dixon, 400,000 vaccination certificates have been sent out, and blanks are still being issued through the mails at the average rate of 1,500 per day.——According to the information prepared by Attorney-General H. L. Carson for Nathan C. Schaeffer, state superintendent of public instruction, fines can not be imposed on parents or guardians for the non-attendance of pupils who have been excluded from the public schools on the ground that they did not present a certificate of successful vaccination. Concerning the attorney-general's opinion, Dr. Brooks, superintendent of the Philadelphia public schools, said that he did not expect much trouble with the schools there, because of the refusal of parents to have their children vaccinated. Most of the parents, he said, believe in the efficacy of vaccination. In his experience he does not recall half a dozen instances in which the parents refused or even strongly objected to the vaccination of their children.

Beaver County Society Meeting.—The Beaver County Medical Society held its semi-centennial meeting December 7 at the Beaver Valley Country Club. Dr. Paul G. McConnel, New Sheffield, presided, and Dr. Jefferson H. Wilson, Beaver, acted as toastmaster at the banquet. Dr. George Y. Boal, Baden, gave a brief history of the society and detailed the early struggles and trials of the old-time practitioner. The guest of the evening, Dr. James Tyson, Philadelphia, read an interesting paper on the "Ideal General Practitioner." The one essential which he emphasized was that thorough medical education should be founded on a broad and liberal preliminary education. After graduating, the ideal physician should be punctual, careful and painstaking; each case should be made a careful study, thus making his experience more useful to him from time to time. The physician should not neglect the study of general literature, though it should, of course, be subordinate to his medical studies and duties. Dr. Tyson also emphasized the importance of all recent graduates connecting themselves with the local medical societies. Dr. Thomas D. Davis, Pittsburg, made reminiscent remarks of the last half-century and Dr. J. Chris. Lange, Pittsburg, dean of the Western Pennsylvania Medical College, dwelt on the importance of practitioners joining their local medical societies whether they belong to other societies or not.

Philadelphia.

Hospital Acquires Property.—The trustees of the Samaritan Hospital have purchased property on Ontario Street, 69x100 feet, adjoining the hospital, for $3,500.

Donations.—The donations received in cash by the German Hospital on its annual donation day, November 30, amounted to $8,030.75.——The Jefferson Maternity Hospital at its annual donation day, November 30, received $300 in cash.

Free Beds for Consumptives.—At the regular monthly meeting of the board of managers of the Free Hospital for Consumptives, held in Philadelphia November 24, it was decided to increase the free beds at the White Haven Sanitarium to 100.

Hospital Reports.—In the Charity Hospital 280 medical and 191 surgical cases were treated during November.——There were 63 patients under treatment in the Kensington Hospital; 60 operations were performed, and 42 new and 148 old patients were treated in the dispensary.

Maternity Home Dedicated.—The new maternity building of the Presbyterian Hospital was dedicated with appropriate ceremonies November 28. The building is a four-story brick structure and was built with $42,670 received from an anonymous friend of the hospital in 1902.

Blockley Banquet.—The organization of ex-resident physicians of the Philadelphia Hospital held its annual banquet December 7, Dr. Alfred Stengel acting as toastmaster. The following officers were elected for the ensuing year: President, Dr. Edward L. Duer; vice-presidents, Drs. Horatio C. Wood and Roland G. Curtin; secretary, Dr. Edward R. Stone, and chairman of executive committee, Dr. Edward E. Montgomery, all of Philadelphia.

Money for Hospitals.—It is stated that $1,500 was realized from a concert given in the Hotel Walton for the benefit of the Oncologic Hospital, November 21.——By the will of the late Mary Lockery the Philadelphia Home for Incurables receives $5,000.——The executive committee of the annual charity ball, at a meeting November 17, selected the following four institutions as this year's beneficiaries: The University Hospital, Jefferson Hospital, Howard Hospital, and St. Timothy's Hospital.

Dr. Coplin's Advisory Board.—On December 7 Mayor Weaver announced the appointment of the following advisory board of physicians to assist Dr. Coplin in the execution of his plans: Drs. S. Weir Mitchell, John H. Musser, John M. Anders, Hobart A. Hare, J. William White and Henry Leffmann. In addition the mayor, after consultation with Dr. Coplin, appointed the following men a committee to investigate the insane department of the Philadelphia Hospital: Drs. Charles D. Mills, Francis X. Dercum, and William Pickett.

Personal.—Dr. J. William White was summoned to Washington to discuss with President Roosevelt certain phases of football.——Dr. John Marshall was a guest at the second annual banquet of the alumni of the University of Pennsylvania of Northumberland district, held in Sunbury, November 15.——Dr. Samuel S. Stryker was presented with a loving cup at the thirty-fourth anniversary of the West Philadelphia Medical Book Club, December 4.——Dr. Richard C. Norris, president of the Philadelphia County Obstetrical Society, entertained at dinner on December 7, as guest of honor, Dr. Robert L. Dickinson of Brooklyn.

Medical Boat for the Soudan.—Through the efforts of Rev. William M. Anderson a boat has been secured for Dr. Hugh Magill for his medical missionary work in the Egyptian Soudan. The boat is 60 feet long and 15 feet wide and is provided with quarters for the crew at one end and an operating room and physician's quarters at the opposite end. The headquarters of the boat will be at "Doliob Hill" station on the Sobat River, a tributary of the White Nile. The boat will leave this station every two months for its first Abysinnian station, 289 miles up the Sobat. Dr. Magill will establish clinics at the different villages and the more serious cases will be brought back to Doliob Hill.

Health Report.—The total number of deaths for the week ended December 9 reached 479, as compared with 463 reported last week, and 453 reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 13; measles, 4; diphtheria, 14; tuberculosis, 52; cancer, 29; apoplexy, 22; heart disease, 43; acute respiratory disease, 91; gastritis, 6; enteritis, 25; Bright's disease, 37; suicide, 3; accident, 14, and marasmus, 8. There were 291 new cases of contagious disease reported, with 29 deaths, as compared with 194 cases and 31 deaths for the preceding week. Typhoid fever is on the increase. There were 152 new cases, with 13 deaths, as compared with 109 cases and 12 deaths for the previous seven days. The sections of the city supplied with filtered water are practically free from the disease, while the major portion of the cases are reported from localities supplied with "raw" water.

Conditions at Blockley.—Since the appointment of Dr. W. M. Late Coplin as director of the Department of Health and Charities a general investigation of the condition of the Philadelphia Hospital has been inaugurated. An advisory board appointed by the mayor found the hospital in a state of confusion. The report presented by Drs. Dercum, Mills and Pickett shows that the insane department contains over 1,800 patients and the space allotted to this number, if conducted under modern methods, should not accommodate more than 700 or 800. The report further states that the buildings are wholly unhygienic and unsafe. The supplies received are entirely inadequate for the demands made. The supplies are about the same now for 1,800 patients as when the number was only 1,400. The committee further found that the patients were not provided with sufficient clothing. Another very undesirable condition was the intermingling of patients suffering from various diseased conditions, particularly the tuberculous patients. The number of paid medical attendants was also said to be entirely insufficient. It may be stated, the report says, that the number of both physicians and attendants is about one-half or less than one-half the number employed in other institutions of this country where large numbers of the insane are collected. Dr. Coplin in his investigation has learned that the cost (34 cents) of keeping a patient at Blockley a day is less than at any other institution in this country.

TENNESSEE.

Smallpox.—Many cases of smallpox have appeared in Claiborne County.

Personal.—Dr. W. Frank Glenn has been made a member of the Board of Health at Nashville.——Dr. William A. Applegate, Chattanooga, chief surgeon of the Southern Railway, has moved to Washington, D. C.——Dr. Elizabeth C. Kane, Memphis, has returned from the East.

Progress of New College.—A stockholders' meeting of the College of Physicians and Surgeons, Memphis, was held November 26, at which organization was partially effected. Dr. Heber Jones was elected president, and Dr. Edward C. Ellett, vice-president. The trustees of the institution are: Drs. Heber Jones, Edward C. Ellett, John M. Maury, Maximillian Goltman, George G. Buford, Richmond McKinney, and William Krauss.

Wins Damage Suit.—The Supreme Court has decided in favor of the appellant in the damage suit brought by J. M. Burd against Drs. C. G. Gates and J. P. Milbanks, Chattanooga, for alleged malpractice. In the lower court a verdict was returned for the plaintiff in the sum of $500, but this verdict was reversed by the Supreme Court on the ground that "from the evidence of plaintiff himself and plaintiff's witnesses, this court is of the opinion that there is no evidence to sustain the verdict of this case, and the same is therefore reversed."

Annual Meeting of Society.—At the annual meeting of the Rutherford County Medical Society, held in Murfreesboro, December 6, the following officers were elected: Dr. James B. Murfree, Sr., Murfreesboro, president; Dr. James J. Rucker, Overall, vice-president; Dr. Rufus Pitts, Murfreesboro, secretary and treasurer; Dr. Enoch H. Jones, Murfreesboro, censor (re-elected); Dr. V. K. Earthman. Murfreesboro, delegate to the Tennessee State Medical Association, and Dr. Harry C. Rees, Murfreesboro. alternate. Drs. James B. Murfree, Sr., James J. Rucker and Rufus Pitts were appointed a committee to formulate a program for the ensuing year.

TEXAS.

Epidemic of Rabies.—It is said that ten persons in Nacogdoches have been bitten by rabid dogs in the last few days.

Clinic Opened.—The San Antonio Medical and Surgical Clinic has been incorporated without capital stock, with the purpose of "free treatment of the indigent poor and promulgation of medical knowledge to doctors." A building has been secured on Third Avenue and the dispensary was opened for the reception of patients on November 27.

Non-paying Patients.—Many of the county medical associations of the state are now adopting the following resolution:

> "We further agree to refuse to give service to any delinquent, who will not pay or make an effort to pay his former physician, without the cash or such security as will insure payment, or the cash at *each and every visit* for a reasonable length of time; then the physician that is favored must insist that the former physician must be settled with in some manner satisfactory; if the patron refuses to do so, his physician must set him aside by refusing him further service. We do not mean by delinquent to include the poor and needy and invalids who come under the head of charity."

The attorney-general was asked to determine whether or not this agreement was a violation of the trust statute of the state and held that it is not a violation.

UTAH.

In Peril of Fire.—The burning of the public school building at Sunnyside, November 11, placed the adjacent Utah Fuel Company's Hospital in grave jeopardy, but the building was saved by prompt action of the company's fire department.

Personal.—Dr. George W. Middleton, Parowan, has been appointed deputy quarantine physician for Iron County, vice Dr. Donald A. McGregor, on leave of absence.——Dr. Samuel H. Pinkerton, Salt Lake City, is confined to his room from injuries received in a runaway accident.

Epidemic Diseases.—The district schools in Iron County, which were closed about five weeks ago on account of an epidemic of scarlatina, have not been reopened on account of the persistence of the disease. The local board of health has prohibited all children under 15 years of age from attending public gatherings.——It is reported that there are 20 cases of diphtheria at Fountain Green.

VERMONT.

Epidemic in Orphanage.—Seventeen girls in St. Joseph's Orphan Asylum, Burlington, were taken suddenly ill October 26, and three died. At the autopsy it was decided that the death was due to poison, the nature of which has not yet been determined.

Medical Monthly Sold.—The *Vermont Medical Monthly* has been transferred by Dr. H. Edwin Lewis to Drs. Henry C. Tinkham, dean of the medical department of the University of Vermont; Bingham H. Stone, director of the State Laboratory of Hygiene; Charles F. Dalton and H. L. White, secretary of the medical faculty of the University.

Personal.—Dr. Herbert B. Hanson, Barre, arrived at Alexandria, Egypt, November 21 on his way to his station on the Upper Nile.——Dr. Patrick J. McKenzie, Burlington, has been appointed a member of the staff of the Danvers (Mass.) Hospital.——Dr. W. R. Blossom, Rutland, was fined $100 and costs at Rutland, October 9, for killing a deer out of season.

Medical College Opens.—The opening lecture of the medical department of the University of Vermont, Burlington, was given by Dr. Don D. Grout, Waterbury, December 2. Dr. J. H. Lockart, Montreal, has been elected professor of gynecology in place of Dr. A. Lapthorn Smith, Montreal, resigned, and Dr. Samuel E. Maynard has been chosen adjunct professor of gynecology.

VIRGINIA.

Northern Neck Medical Association.—This association met at Warsaw, with Dr. James W. Tankard, Lilian, Northumberland County, president, and Dr. R. O. Long, secretary. Fourteen other physicians, representing every section of the counties of Richmond, Lancaster, Westmoreland and Northumberland, were present.

Students Barred from Hospital.—The committee on relief of the poor has adopted a resolution that the professors and students of the medical colleges of Richmond should be barred from the hospital in the future. It was alleged by the chairman of the committee that the colleges of the city were sending professors and students to the hospital to hold clinics, using the inmates for purposes of demonstration, and that many of these patients objected to the practice.

Personal.—The board of visitors of the University of Virginia has elected Dr. William Mann Randolph, Charlottesville, clinical instructor in surgery and adjunct professor of surgery, vice Dr. William G. Christian, Charlottesville, resigned.——Dr. Ernest C. Levy, Richmond, has been elected city bacteriologist for a term of two years.——Dr. J. C. Witten, Richmond, has been appointed instructor in minor surgery at the Medical College of Virginia.——Dr. Charles L. Culpepper, Portsmouth, has been appointed local surgeon for the Norfolk, Portsmouth & Newport News Company's system.

WASHINGTON.

Postgraduate Work in Spokane.—The members of the Spokane Medical Society are preparing for a course of lectures and laying out a plan to give to the physicians of the Northern Pacific slope the benefits ordinarily derived from attendance on a postgraduate course in a medical institution.

Personal.—Dr. Yancey G. Blalock, Walla Walla, has been removed from the position of physician to the state penitentiary.——Dr. H. Wellard Howard, Spokane, is ill with typhoid fever.——Dr. William E. Fifield, Tacoma, is critically ill.——Dr. B. H. Yount, formerly of Wilbur, has been released from the State Hospital for the Insane, Medical Lake.

New Antivaccination Tactics.—After making a thorough investigation of the statutes in various states concerning the vaccination of school children the Antivaccination Society of Bellingham ascertained that the cause of questioning the validity of the law would be of no avail, and it is now endeavoring to compel the board of health and the school board to make a literal enforcement of the law.

Hospital News.—A contract has been awarded by the trustees of St. Luke's Hospital, Spokane, for the construction of a maternity wing which will accommodate 50 patients and will represent an outlay of about $50,000.——Dr. Watanabe will open a hospital in Seattle for the exclusive use of Japanese patients.——St. Joseph's Hospital, Aberdeen, is so overcrowded that it has been necessary to convert the dining-room into a ward.——It is proposed to erect a hospital building to accommodate 30 patients in Wenatchee.——A permit has been granted for the erection of one wing to the Deaconess Hospital, Seattle, to cost $16,000 and to accommodate 45 patients.

Medical Men Must Have License.—The Supreme Court of Washington has sustained the conviction of O. V. Lawson of the notorious State Electro-Medical Institute, Seattle, charged with practicing medicine without a license. In its decision the court declares that the unamended sections of the medical act of 1890 and the three sections of that act as amended in 1901 are in full force and constitute the law. The defendant's contention was that, because the amended act had failed to set out in full the old law, if changed, it was unconstitutional. This the Supreme Court declares was once accepted by the court, but is no longer approved. By virtue of this decision the court affirms the ruling of the law of the lower court and declares that the $384 unlawfully obtained from the complainant, Calvin C. Deaton, must be refunded.

WEST VIRGINIA.

Personal.—Dr. Abraham S. Warder, Grafton, is seriously ill with rheumatism.——Dr. Horace M. Brown has been appointed a member of the local board of health of Union.

Smallpox.—The smallpox situation in Wellsburg is now believed to be under control. At present there are 14 cases in the city and under strict quarantine. The disease has appeared in a very mild form and the board of health has done good work in controlling the conditions.

Diphtheria.—More than 20 cases of diphtheria have been reported from Bergholz, Jefferson County. The delay in acknowledging the presence of the disease was due to a difference in opinion between two physicians as to whether or not the condition was diphtheria.——At Byron, where 16 cases were alleged, 5 cases only exist.

WISCONSIN.

Diphtheria.—Diphtheria is reported to be epidemic in the Tenth Ward of La Crosse.——In Kenosha 60 cases of the disease have been reported.——The schools at Iron River have been closed on account of the prevalence of diphtheria.

District Meeting.—The annual meeting of the North Wisconsin District Medical Society was held in Eau Claire, November 22. Dr. Edward H. Grannis, Menominee, was elected president; Dr. Frank W. Epley, New Richmond, vice-president, and Dr. Hiram A. Fulton, Eau Claire, secretary. It was decided to hold the next meeting in Eau Claire, Nov. 3, 1906.

Hospital News.—The late Mrs. Mary C. Stuart, Madison, devised $3,000 in her will for the benefit of the Madison Hospital building fund.——By the will of Julia Gertner, Milwaukee, $500 is bequeathed to the Milwaukee Hospital.——Dr. Edward A. Miller, Clintonville, will open a private hospital in that city.——The new Milwaukee Deaconess Mother House, Milwaukee, was dedicated November 23.

Smallpox.—The public schools and churches in Seymour have been closed and all public meetings have been postponed on account of smallpox, of which 15 cases have been reported.——A hospital ward has been established at the State School for the Blind, Janesville, where 15 cases of smallpox have been reported. The school is still quarantined. Janesville is said to have at least 100 cases of smallpox; 70 houses have been quarantined.

Personal.—Dr. and Mrs. Herman F. Oshwaldt, Oconto Falls, while driving near that village, were injured in a runaway accident. Mrs. Oshwaldt sustained severe injuries about the head and spine and broke three ribs, and Dr. Oshwaldt received some bruises about the head, but was not seriously injured.——Dr. William F. Beutler, Wauwatosa, has been reappointed superintendent of the Asylum for the Chronic Insane, Wauwatosa.——Dr. Hayes, Stanley, has been re-elected physician of Chippewa County.——Dr. and Mrs. M. E. Corbett, Oshkosh, have returned from an eight months' trip abroad.——Dr. William W. Reed, Jefferson, has been elected physician of Jefferson County for the fifteenth time.——Lieutenant Otto B. Bock, assistant surgeon W. N. G., Sheboygan, has resigned.——Dr. William O. St. Sure, Sheboygan, has been re-elected physician of Sheboygan County.——Dr. Gustav A. Kletzsch, Milwaukee, has resigned as president of the Milwaukee County Hospital staff.——The following physicians have been appointed for Milwaukee County: Drs. Albert F. Young, William Lochemes, Louis F. Klemm, J. H. Rohr, Charles A. Faber, A. E. Schmitz and A. C. Sidler.——Dr. John W. Coon has been appointed superintendent of the Milwaukee County Hospital, vice Dr. Ernest C. Grosskopf.

WYOMING.

License Revoked.—The State Board of Medical Examiners has revoked the medical certificate granted Dr. W. R. Wilson, who left Caspar in August last. The cause of the revocation was that Dr. Wilson obtained the certificate through false representations and also on account of unprofessional conduct.

Fire at Hospital.—A barrel of alcohol which was stored in the basement of the Sheridan Branch of the Wyoming General Hospital exploded October 20, fatally burning an employe and setting fire to the hospital. The 19 patients in the institution were removed in safety. The damage to the hospital amounted to about $800.

Personal.—Drs. Harry S. Finney, Rawlins, is ill in Omaha with typhoid fever.——Drs. Henry Stevens and Herman E. McCallam, Laramie, have been appointed local physicians for the Union Pacific System.——Dr. Charles E. Downey, Evanston, has been appointed physician for the Utah Construction Company, and will have charge of all camps operated along the line of the Western Pacific Railroad in Utah and Nevada.

Removed from Office.—At a meeting of the Sheridan County Medical Society, held in Sheridan November 6, Dr. C. R. Halley, president of the society, was, by a unanimous vote of the members present, removed from office for conduct unbecoming an officer of the society. The specific complaint preferred against Dr. Halley was violation of a written agreement signed by several members of the society not to assist nor to consult with the medical director of the Sheridan General Hospital.

State Society Meeting.—The annual meeting of the Wyoming State Medical Society, postponed from September 27-29, was held in Cheyenne, December 7. The following officers were elected: President, Dr. William A. Wyman, Cheyenne; vice-presidents, Drs. Fred Horton, Newcastle, and Ernest A. Croskery, Wheatland; secretary, Dr. George L. Strader, Cheyenne; treasurer, Dr. A. Francis Hoff, Casper; delegate to the American Medical Association, Dr. Henry L. Stevens, Laramie, and alternate, Dr. Alfred C. Godfrey, Lander. The next annual meeting of the society will be held at Casper. The date of the meeting has not yet been set. The entire session was well attended and a large number of Wyoming physicians were elected to membership.

GENERAL.

Yellow Fever in Cuba.—According to *Public Health Reports*, no new cases of yellow fever have been reported since November 26.

Superior and Duluth Society Election.—The Interurban Academy of Medicine, composed of physicians of Superior, Wis., and Duluth, Minn., held its annual meeting November

15. Dr. Luther A. Potter, Superior, was elected president, Dr. Charles F. McComb, Duluth, vice-president, Dr. Lewis Moody, Superior, secretary and treasurer, and Dr. Louis T. Pare, Duluth, censor.

Big Four Surgeons Meet.—The Association of Big Four Railroad Surgeons held its eleventh annual meeting in Cincinnati November 2. The following officers were elected: Dr. E. Memmen, Bloomington, Ill., president; Dr. F. D. Bain, Kenton, Ohio, vice-president; and Dr. T. C. Kennedy, Shelbyville, Ill., secretary and treasurer. Indianapolis was chosen as the next place of meeting.

Literature on Study of Alcohol Problem.—Dr. T. D. Crothers, Hartford, Conn., desires the names and addresses of medical men who would be pleased to receive from time to time literature on the scientific study of spirit and drug neuroses and the alcoholic problems generally. The objects are to enable authors to reach appreciative readers and to promote co-operative interest in the study.

Epilepsy Prize.—The National Association for the Study of Epilepsy offers a prize of $300 for the best essay on the "Etiology of Epilepsy." Physicians in any country may compete. The award will be made in November, 1906, but all essays submitted must be sent in by Sept. 1, 1906. Details as to conditions governing the award may be obtained from Dr. W. P. Spratling, superintendent of the Craig Colony for Epileptics, Sonyea, N. Y.

Seaboard Medical Association.—The annual meeting of this society just closed resulted in the election of the following officers: Dr. John C. Rodman, Washington, N. C., president; Drs. Benjamin R. Gary, Newport News, Va., first, E. C. Hathaway, Bloxom, N. C., and J. W. Bowden, Accomac, Va., vice-presidents; Dr. W. D. Hassell, Griscom, N. C., treasurer; Dr. Israel Brown, Norfolk, Va., secretary. This society is composed of physicians of Virginia and North Carolina living along the Atlantic seaboard.

Fix Standards for Food Purity.—The committee on food standards of the Association of Official Agricultural Chemists, commissioned by Congress to collaborate with the Secretary of Agriculture in fixing standards for purity for foods, finished its sessions in Boston. It consists of Dr. William Frear of Pennsylvania, Dr. E. H. Jenkins of Connecticut, Dr. M. A. Scorell of Kentucky, Dr. A. H. Weber of Ohio and Dr. H. W. Wiley of Washington. They discussed meat extracts, peptones, fruits, vegetables, flavoring extracts, edible vegetable oils, salts, teas, coffee, fresh fruit juices, meat, root beer, malt liquors, spirituous liquors, carbonated water, preservatives and colors. Already some standards have been fixed and adopted by many states.

National Association for the Study of Epilepsy.—The following officers were elected for the ensuing year: President, Dr. Max Mailhouse, New Haven, Conn.; vice-presidents, Dr. Everett Flood, Palmer, Mass., and Dr. William F. Drewry, Petersburg, Va.; secretary and treasurer, Dr. James W. Wherry, Dansville, N. Y. Very interesting reports were given of the progress in securing the treatment of epileptics separate from the insane. Many instances in which colonies for epileptics had been put on a self-supporting basis were cited and the general outlook was said to be distinctly encouraging. Emphasis was laid on the emancipation from the idea that the only treatment for epilepsy was confinement and the use of bromids. To-day over 20 per cent. of patients are cured.

Cholera in the Philippines.—Chief Quarantine Officer Heiser reports that the total number of cases of cholera in Manila since the beginning of the outbreak is 210, with 183 deaths; the total number in the provinces is 437, with 236 deaths. In regard to the interisland quarantine, he states that in view of the urgent necessity for more frequent communication with the provinces on account of the conditions which were brought about by the recent typhoon, and the fact that the quarantine had been in operation for nearly two months with only 1 case of cholera making its appearance on a vessel undergoing quarantine detention; and, furthermore, since experience with cholera during the past three years has demonstrated that for practical purposes the incubation period of cholera is less than three days, it was decided to reduce the period of quarantine on outgoing interisland vessels from five to three days.

Yellow Fever in Panama.—A case of yellow fever was reported in Panama, November 20. The patient was a Colombian who lived in the San Tomas Hospital, the charity hospital in the city of Panama. According to the official report he was taken sick in that institution, admitted to the ward as a patient on November 11, and died on November 20. This is the third case of yellow fever reported on the Isthmus since November 1, one of which, as previously reported, occurred in Colon. Acting Assistant Surgeon Mohr states that as no steps have been taken by the Panama authorities to stamp out the infection in Bocas del Toro, a quarantine has been enforced against that place by the sanitary department. All non-immunes arriving from Bocas will be placed in detention for five days and the small sailing craft bringing such passengers will be fumigated before being allowed to come alongside the docks.

The End of the Yellow Fever Epidemic.—During the last week of November both New Orleans and Vicksburg reported three new cases.——The Louisiana Board of Health gave Governor Blanchard a report of the epidemic and then the members tendered their resignations. Dr. Charles Chassaignac is mentioned for Dr. Souchon's post as president of the new board. It is recalled that at the close of former epidemics the State Board of Health always has resigned with more or less popular satisfaction. It is reliably reported that the Orleans Parish Medical Society will officially investigate the charges brought by Dr. Joseph Holt against Health Officer Quitman Kohnke of New Orleans.——The Pensacola quarantine was finally abandoned on November 19, and on the same day the city council voted a present of $250 to Dr. F. D. Miller, the city health officer, for his work during the epidemic.——In Texas the Jefferson County Medical Society at Beaumont adopted resolutions of confidence in State Health Officer George R. Tabor. The Texas quarantine was finally raised on November 25. Texas spent $22,000 on its quarantine, of which sum $10,000 stands as a deficiency and $12,000 as the entire appropriation for the state health office for the year Sept. 1, 1905, to Aug. 31, 1906. In consequence, an additional deficiency of $15,000 is to be created to carry on the work of the office until the end of the fiscal year.——In Alabama the Jefferson County Medical Society at Birmingham officially thanks State Health Officer Sanders for his work during the epidemic period.——Dr. John Callon of New Orleans received a silver service as a testimonial from friends and neighbors for his work during the epidemic.——Dr. Heber Jones, health officer at Memphis, has received a subscription of $10,000 for his hard work during the period of the epidemic.——At Havana there seems to be a steady increase in the number of new cases of yellow fever.

American Tuberculosis Exhibition.—This exhibition, of which a report was given last week, page 1820, was a great success; over 10,000 people attended the first week and the educational work has had a great opportunity. The offer of the American Federation of Labor has been met and an arrangement for co-operation by the labor unions is probable. On Friday evening, December 8, with Dr. John H. Huddleston of the Board of Health of New York City in the chair, Dr. S. A. Knopf of New York City told how the teacher can assist in fighting tuberculosis. To a large audience of teachers he related the history of this disease and explained at length how the disease is spread by inhalation, ingestion, inoculation and drop infection. The consumptive should hold his hand before his mouth while coughing, as a consumptive who raises no sputum expels 100,000,000 bacilli in twenty-four hours. The symptoms of consumption were outlined, as it is essential that teachers should be acquainted with them. The predisposition to tuberculosis may be inherited or acquired; alcohol plays a large part in causing a predisposition. Aside from beer, more alcohol is sold in patent medicines than over the bar. There is no less than $200,000,000 worth of patent medicine sold in this country every year. The percentage of alcohol in the more popular patent medicines was shown to range from 15 to 35 or even 40 per cent. A fearful responsibility consequently rests on those who recommend these concoctions to their friends or lend their names for the purpose of advertising, yet even ministers of the Gospel and statesmen are guilty of this offense. It must be understood that while tuberculosis is curable, it is not curable by patent medicines, but by good food, fresh air, rest, and a little medicine, judiciously prescribed by a physician. It is the duty of the teacher to prevent consumption among children, and as a consequence among the next generation. Cleanliness in regard to hands, face and finger nails should be insisted on. In France a few lines giving instruction on these matters are on the outside of public school books. The teacher should always remember not to overtax the mind to the detriment of the physical development. A variety of breathing exercises should be taught, also outdoor singing and where possible swimming lessons. Child labor should be abolished. Neither the tuberculous teacher nor the tuberculous child should be permitted in the schools, but provision should be made for both. Sanatoria should be established. Carnegie recognized the need of the college professor in his old age, and some philanthropist might well establish a fund for tuberculous teachers which would pension them or enable them to rest until cured.

CANADA.

Medical Reciprocity with the United Kingdom.—The president of the general medical council, at a meeting recently held in London, England, stated that the effect of the General Laurie amendment (1905) to the British medical act would allow of the provinces of Canada applying for the privilege of medical reciprocity with the United Kingdom. It is expected in England that some, if not all, of the provinces of Canada will extend the same privileges to graduates of the United Kingdom.

Consumption Clinic at the Toronto General Hospital.—Consumptive patients who come to the outdoor department of the Toronto General Hospital will hereafter have the benefits of a special clinic. One of the trustees and another public-spirited citizen have contributed funds to carry on this work. A special nurse has been detailed to visit these patients at their homes and to teach their families how to care for and attend cases of tuberculosis. The clinic will be under the supervision of Professor McPhedran, the chief of the medical staff of the medical faculty of Toronto University.

Toronto Free Hospital for Consumptives.—It is just a little over a year ago that the Toronto Free Hospital for Consumptives, superintended by the National Sanitarium Association, which also conducts the Muskoka hospitals at Gravenhurst, commenced operations. That great interest has been taken in the institution is apparent from the fact that within the space of a year 5,000 persons have registered at the institution, brought there through the illness of friends or from a personal motive. A large addition is now rapidly nearing completion at a cost of $20,000, which will increase the accommodation to between 60 and 70 patients. When this addition is finished accommodation will be provided for a ward for children ranging from 6 to 12 years of age. A citizen of Toronto has recently placed $10,000 at the disposal of the trustees of the institution, and the treasurer, Mr. H. C. Hammond, will erect a cottage at his own expense, at a cost of $5,000.

Hospital News.—A by-law will be submitted to the ratepayers of Hamilton, Ont., in January for the purpose of raising $35,000 to complete the new wing to the general hospital of that city.——The governor-general and Lady Grey visited Montreal December 1 and took part in the opening ceremonies of the new Maternity Hospital of that city.——An additional $5,000 was subscribed to the funds of the Toronto General Hospital during the week ending December 2.——The county council of the County of York, in which the city of Toronto is situated, has been asked by the trustees of the Toronto General Hospital to make a grant to the new hospital, which they will probably do in the near future, seeing that the Toronto General Hospital receives many county patients throughout the year.——In connection with the establishment of the new Alexandra Hospital, Montreal, on a firm financial basis, the committee in charge of finance report that they selected 150 firms of Montreal to whom first to appeal for funds, and that 149 have responded favorably. This is very encouraging to the promoters of the institution, and a new and added zest to the prosecution of the work of collection will most likely result in the accomplishment of the desired end, namely, the raising of $250,000. Of this amount only $130,000 has been collected. The Alexandra Hospital has been erected by arrangement with the city council of Montreal, to accommodate Protestant patients who may be the subject of infectious and contagious diseases.——At the recent regular monthly meeting of the board of trustees of the Winnipeg General Hospital the statistical report for the month of October was presented. It showed that the number of patients treated during that month was 640. The total number of days' stay was 9,507. The number of patients treated from January 1 to November 1 was 3,635. The number of patients in the outdoor departments numbered 440.——Dr. Augusta Stowe-Gullen has been reelected president of the ladies' board of the Western Hospital, Toronto. This board collected $3,456.80 for the hospital this year up to December 1.

The British Medical Association in Toronto.—The seventy-fourth annual meeting of the British Medical Association will be held at Toronto, Canada, Aug. 21-25, 1906, under the direction of the following officers:

President, Mr. George C. Franklin, Leicester, England; president-elect, Dr. Richard A. Reeve, Toronto; treasurer, Dr. H. Radcliffe Crocker, London, England; orator on medicine, Dr. James Barr; orator on surgery, Sir Victor Horsley.

SECTIONS.

Anatomy and Physiology.—President, Prof. Bertram C. A. Windle, Cork, Ireland. Secretary, Dr. C. B. Shuttleworth, Toronto

Dermatology.—President, Dr. Norman Walker, Edinburgh, Scotland. Secretary, Dr. D. King Smith, Toronto.

Laryngology and Otology.—President, Dr. J. Dundas Grant, London, England. Secretary, Dr. David J. G. Wishart, Toronto.

Medicine—President, Sir Thomas Barlow, London, England. Secretary, Dr. Robert D. Rudolf, Toronto.

Obstetrics and Gynecology.—President, Dr. A. H. Freeland, Edinburgh, Scotland. Secretary, Dr. Frederick Fenton, Toronto.

Ophthalmology.—President, Mr. Robert M. Gunn, London, England. Secretary, Dr. James M. Maccallum, Toronto.

Pediatrics.—President, Dr. George A. Sutherland, London, England. Secretary, Dr. E. Stanley Ryerson, Toronto.

Pathology and Bacteriology.—President, Prof. J. G. Adami, Montreal. Secretary, Dr. Gideon Silverthorn, Toronto.

Psychology.—President, Dr. William J. Mickle, London, England. Secretary, Dr. A. T. Hobbs, Guelph.

State Medicine.—President, Dr. F. Montizambert, Ottawa. Secretary, Dr. J. Langrill, Hamilton.

Surgery.—President, Prof. Irving H. Cameron, Toronto. Secretary, Dr. H. A. Beatty, Toronto.

Therapeutics.—President, Prof. David W. Finlay, Aberdeen. Secretary, Dr. V. Henderson, Toronto.

ARRANGEMENT COMMITTEES.

Honorary Local Secretaries.—Dr. F. N. G. Starr, Toronto; Prof. J. J. MacKenzie, Toronto; Dr. J. Gibb Wishart, Toronto.

Committee Pathologic Museum.—Chairman, Prof. J. J. MacKenzie, Toronto. Secretary, Dr. Maud Abbott, Toronto.

Exhibition Committee.—Chairman, Dr. Arthur J. Johnson, Toronto. Secretary, Dr. T. D. Archibald, Toronto.

Local Treasurer.—Prof. J. F. W. Ross, Toronto.

Toronto Arrangement Committee.—Dr. George A. Bingham, Toronto; Dr. C. J. C. C. Hastings, Dr. A. A. Macdonald, Dr. J. J. MacKenzie, Dr. Alex. McPhedran, Dr. R. B. Nevitt, Dr. R. A. Reeve, president-elect; Dr. F. N. C. Starr, Dr. J. A. Temple, Dr. D. J. Gibb Wishart.

Reception Subcommittee.—Chairman, Dr. I. H. Cameron. Secretary, Dr. A. Primrose.

Finance Subcommittee.—Chairman, Hon. Dr. R. A. Pyne. Secretary, Dr. William Goldie.

Excursion Subcommittee.—Chairman, Dr. N. A. Powell. Secretary, Dr. C. P. Lusk.

Transportation Subcommittee.—Chairman, Dr. B. L. Riordan. Secretary, Dr. H. A. Beatty.

Dinner Subcommittee.—Chairman, Dr. F. LeM. Grasett. Secretary, Dr. H. A. Parsons.

Subcommittee in Charge of Exhibits.—Chairman, Dr. A. J. Johnson. Secretary, Dr. W. A. Young.

Printing and Publishing Subcommittee.—Chairman, Dr. A. H. Wright. Secretary, Dr. J. N. E. Brown.

Local Entertainments Subcommittee.—Chairman, Dr. H. Crawford Scadding. Secretary, Dr. H. S. Hutchison.

Hotels and Lodgings Subcommittee.—Chairman, Dr. H. T. Machell. Secretary, Mr. F. A. Clarkson.

Membership Subcommittee.—Chairman, Dr. R. W. Bruce Smith. Secretary, Dr. W. H. Cronyn (Rosedale).

FOREIGN.

Plague in Africa.—Consul Hollis of Lourenzo Marquez reports an outbreak of plague at Chinde, with several deaths.

Yellow Fever in Peru.—December 7 the steamer *Loa* arrived at Callas from Panama with eleven cases of yellow fever on board.

Berlin Postgraduate Lectures.—The Berlin Docent-Verein announces the next cycle of postgraduate lectures to commence March 1 and continue to March 28, 1906. The list of subjects and other details can be learned by applying to Melzer, Ziegelstrasse 10, Berlin, Germany.

International Congress for Prehistoric Anthropology and Archeology.—The thirteenth international congress devoted to these subjects will convene at Monaco April 16 to 26, 1906. Further information can be obtained on application to M. Henri Hubert, 74, rue Claude-Bernard, Paris, France.

Exhibition for Tropical Medicine.—During the German "Colonial Congress," held at Berlin, in October, an exhibition of tropical medicine attracted much attention. One of the most interesting exhibits was that of the Woman's League for Care of the Sick in the Colonies. It included a model sick room and kitchen for the tropics.

Less Medical Students in Prussia.—During the fiscal year 1903-4 only 426 degrees were conferred on medical students, and only 363 new medical students were enrolled. The increase in the population and the losses in the profession by death or incapacity require an increase of 550 physicians every year to meet the demand, according to the statisticians. The decrease in the number of medical students is making itself felt in a lack of assistants and substitutes, the supply being much below the demand. The ranks of the practicing physicians still show no gaps, owing to the former overcrowding. The lack is in the younger set.

Darmstadt Police Regulation of Quack Ads.—The city of Darmstadt, Germany, has issued orders that impose a minimal penalty of 30 marks ($7.50) for publishing or advertising articles, remedies or methods of treating or preventing disease in human beings which are liable to injure the health, or in regard to which erroneous or misleading statements are made or deception practiced. The same penalty is imposed also for treatment by letter without personal examination, and also on those who recommend a *Heilgewerbetreibenden*, that is, a person making a business of the healing art outside of professional circles, by false or misleading statements in regard to his preliminary training, capability or successes.

Plague in China.—Consul-General Sammons, Niuchwang, reports that at a meeting of the consular body, held at the American consulate-general, in that port, immediately after the notice of the existence of the plague there, it was agreed to co-operate in the enforcement of every necessary precaution in stamping out the disease. Steps have been taken to isolate the infected locality and to conduct a careful medical inspection of the inhabitants within the isolated limits. All passes authorizing the owners to take passage on the military train at Niuchwang for the interior have been nullified. No vessels are to be allowed to go up to Liao until further notice. Traffic between Yingkow and Niuchwang is suspended.

Centennial of Paris Medical Society.—The Société Médico-Chirurgicale celebrated, November 20, the hundredth anniversary of its foundation. It was organized in 1805 by Dr. Duchateau and was called at first the "Confraternelle Médico-Chirurgicale." Membership has always been limited to a certain number, and Desnos, the president, in his address remarked that the society has always been true to its traditions of "work, warm friendship between truly congenial spirits, and solidarity." A banquet followed the anniversary meeting, with a theatrical entertainment and the presentation to each member of an artistic souvenir plaque. An illustration of this souvenir is given, with the description of the celebration, in the *Archives Gén. de Médicine* for November 28.

Study Leave for Officers of the Indian Medical Service.—New regulations have been issued recently with regard to "study leave" for officers of the Indian Medical Service. Extra furlough for study may be granted to officers of the Indian Medical Service on the recommendation of the director general. The period of such leave will be calculated at the rate of one month for each year of service up to a total of twelve months in all during an officer's service. The leave may be taken at any time, but will not be granted more than twice in an officer's service. The minimum period for this leave will be two months and this leave can be combined with any other kind of leave. A sum will be allowed for expenses, the amount depending on the rank of the officer. Study leave will count as service for promotion and pension.

"Leipziger Verband" Engages in Campaign Against Quackery.—The latest news from the German Leipziger Verband ("to promote the economic interests of physicians") is that it has now 18,000 members and rates at more than 8,000,000 marks, about $2,000,000, the increase in the amounts paid by the sickness insurance societies (Krankenkassen) to their medical officers during the last year. This has been accomplished by the direct or indirect backing of the profession organized in this Verband, founded only five years ago. It now announces that a committee has been formed to take up the matter of quackery, and unite with medical and local authorities and local societies to inaugurate extensive and systematic concerted action in a campaign against irregulars. There is already an association for this purpose in Germany, and it is proposed to work in harmony with this organization.

Maternity Work in India.—The Dufferin Fund and Victoria Memorial Scholarship Fund have been presided over by Lady Curzon for nearly seven years, and the work has progressed most satisfactorily. The number of patients attended to at the various women's hospitals has increased considerably and a large number of midwives are under training. The hospitals are being used as training centers and there are now ten more qualified women physicians, seven more assistant surgeons, and 337 more hospital assistants than in 1898. At present 476 women are under medical training apart from dhais and nurses. A fully equipped operating room has been provided in all the hospitals. Under the Victoria Fund, some 286 dhais have been trained and 160 more are undergoing instruction. Only those who know the mortality of childbed in India and the fearful "massacre of the innocents" which is continually going on will recognize to the full the good work which is being done by these two funds.

English-Speaking Meetings in Japanese Medical School.—The *Sei-I-Kwai, No. 5,* contains the address delivered by Dr. L. L. Seaman, before he left Japan, at a meeting of Japanese medical students, at which *only* English was spoken. Five addresses were read by students, the subjects being "Why We Breathe"; "Use of Stomach"; "What Our Skin Does," and similar themes. Seaman qualified the meeting as "unprecedented in the records of professional instruction—a meeting of the entire body of students in a great professional school, in which all of the proceedings were conducted in a foreign tongue, and these exercises were part of the regular curriculum." These English meetings are held at stated intervals at the Tokio University. Seaman commented on the addresses delivered by the students that they revealed the secret of the absence of disease among the Japanese soldiers, especially the address on the stomach. "Your army and navy management," said he, "did not load the stomachs of your soldiers with food that was unsuited to the climate, and that caused fermentation and irritation in the intestinal tract as was the case in our war with Spain."

Practice of Medicine in Buenos Ayres.—A bill to regulate the practice of medicine in the province of Buenos Ayres has been before the parliament of the Argentine Republic for some time, and has been passed in part with only slight modifications. By this measure medical consultations in pharmacies are forbidden. Advertisements in which a cure of all or certain specified diseases, whether at a stated price or otherwise, is promised, are declared to constitute illegal practice. In the same category will fall statements that a therapeutic agent is of infallible efficacy in one or more diseases. The bill provides that a fine shall be imposed on whomsoever shall, directly or indirectly, contribute to the publication of such advertisement. The obligation of professional secrecy is remitted in special cases in which its observance would be attended with danger to the public health or interfere with the penal laws. Special permission is required for the sale of prophylactic or curative serums, modified toxins or organic liquids intended for the cure of diseases; it is also provided that the preparation of these substances shall be subjected to special supervision.

Prophylaxis of Cholera.—The Prussian authorities have announced that in the recent epidemic of cholera in Germany it was found that a number of cases occurred in workmen engaged in haying or working along the shore without any personal contact with the cases of cholera that had occurred along the infected rivers. This fact suggests that the workmen must have become infected by drinking water from the river at points where the water had become infected by contamination from a fresh case of cholera. It is a question whether the cholera germs can be transported by the river to any distance from the point of contamination. The presumption is that they linger in stagnant bays and backwater nooks along the river banks, where they possibly proliferate. To determine this question the authorities have decreed that whenever a new case suspicious of cholera is discovered on a river boat, a number of quart bottles are to be filled with water drawn from the river above and below the spot where the vessel is lying at the time. The bottles must be packed in ice and dispatched in charge of a responsible person to the nearest "investigation station," after previously informing the station by telegraph of the attending circumstances. The decree is given in full in the *Allg. med. Ct.-Ztg.* for November 25.

The Milk Supply of Calcutta.—The Indian correspondent of the *Lancet* states that a committee of the corporation of Calcutta has recently submitted a report on the milk supply of that city which discloses a horrible state of things. In the majority of cases "the cattle were in a filthy condition and were standing in the offensive-smelling filth, inches deep; their udders were covered with muck; the cattle were packed together so closely that there was no room for them to lie down; the sheds were ill-ventilated, the entrances being blocked by platforms on which the gowalas (cow-men) slept, all the air-holes being closed up with mud bricks. This condition of the cow houses has been existent for years. The health officer suggested that certificates should be granted to those dairymen who conduct their business along proper sanitary lines, but the utter inadequacy of such a proposal is evident from the continued failure of the prosecutions instituted, and the committee has ignored the suggestion and has made recommendations of a drastic character. The most important proposal is to establish municipal cattle sheds provided with every convenience and to rent them at a reasonable sum. The difficulties connected with enforcement of the provisions of the municipal act are so great that the corporation will have to do a great deal in supplying filtered water, filling up insanitary tanks, prosecuting more vigorously, and arranging for more thorough and constant inspection. A large quantity of milk is taken into Calcutta from the suburban areas and examinations of this supply have shown very extensive adulteration. The danger of this is that the gowalas will use any dirty water and do not confine themselves to the filtered town supply.

Koch's Report on His Expedition to Eastern Africa.—The preliminary report published by R. Koch in regard to his scientific researches during his year's stay in German East Africa is published in the *Deutsche med. Wochft.* for November 23. He devoted considerable attention to the prevailing relapsing fever, leprosy and sleeping sickness in man and to coast fever and Texas fever in cattle. In an expedition on the main caravan route none of the three Europeans in the party was affected with the endemic relapsing fever. None of them slept in the shelters provided for the caravans, but sought places to sleep where no one had laid before. This was done to avoid the ticks which harbor the spirochetes causing relapsing fever. He found it impossible to infect cattle, dogs or other animals with the disease by inoculating them with blood from cases of relapsing fever. The only exception was monkeys; all his experimental inoculations of monkeys resulted positively. The tick communicating the disease is the *Ornithodorus moubata Murray.* It lives in the soil in the floor of the native huts and shelters, wherever the ground is not exposed to the rain. The spirochetes are found mostly on the ovaries and in the eggs of the tick. The natives are probably infected during youth and acquire immunity later. None of his 60 native porters contracted the disease, although they slept in the shelters, while 4 out of the 5 servants accompanying the party had the fever. They slept also in the shelters. Koch illustrates the cycle of development of the parasite of Texas fever as he traced it in three different varieties of ticks. Also of the parasite of coast fever, which he found only in adult ticks of a certain variety—*Rhipicephalus australis.* He encountered 4 varieties of tsetse flies, and established that the tsetse disease is communicated by the intermediation of 3 of them, the *Glossina morsitans, pallidipes* and *fusca,* especially the latter. Both males and females bite and can become infected, but the female does not lay eggs. It deposits a single whitish larva which assumes the pupa form in a few hours. From ten to twenty days elapse between the birth of these larvæ, so that the female produces only two or three young in the course of a month. This fact may prove important in prophylaxis of the trypanosoma affections. He established further that not all trypanosomata are capable of infecting the glossina, only those which are in a certain condition. Possibly this condition is encountered in the parasites in wild, not domestic, animals.

Yellow Fever in Central America.—Acting Assistant Surgeon Peters, of the Public Health and Marine-Hospital Service, gives an interesting account in *Public Health Reports* of the yellow-fever situation in Central America. The disease made its appearance in Zacapa during the latter part of June. The infection was introduced from Livingston through natives who were permitted to return to their homes in Zacapa after the outbreak of the fever in Livingston, but was not recognized as yellow fever until August, by which time the infection was thoroughly disseminated throughout the town, there being hardly a house in the place which has not had a case of yellow fever. Dr. Peters was unable to obtain any reliable information as to the number of cases or deaths, but well-informed and reliable residents estimate the number of deaths at about 700. At the time of his visit the public health was fairly good. Only a few cases of yellow fever existed, as the force of the epidemic had spent itself and the available material was practically exhausted. At the time of the outbreak of yellow fever a great number of people left and went to the mountains, leaving only about 3,500 in the place during the height of the fever, and it is these returning and others from the adjoining places who come into Zacapa who are furnishing the material for keeping up the infection. This is the first time yellow fever has ever appeared in Zacapa. Sulphur has been burned on the street corners with the idea of purifying the atmosphere. No attempt has been made to destroy the infection in the place used as a lazaretto during the epidemic. It was simply a thatched shed with the sides inclosed, and was used for treating the poor. It could easily have been burned, as it would be impossible properly to fumigate it. Gualan is situated on a hill, and is about 500 feet above sea level. It has a population of about 1,500. It is on the railroad, 80 miles from Puerto Barrios and 21 miles from Zacapa. The first cases of yellow fever came under observation in August. The yellow-fever patients in the railroad hospital were kept under bars, and every precaution was used to prevent the spread of the infection, no standing water being allowed around the buildings; but in the town itself nothing has been done. Dr. Peters states that one of the foci is in the barracks itself, in which a number of cases of yellow fever have developed and are still developing, no effort being made to destroy the infection. All along the line of the railroad from Puerto Barrios to Zacapa, wherever there is a station, he invariably found the stegomyia present.

LONDON LETTER.

The President of the Royal College of Surgeons on Medical Education.

At a dinner given at the Society of Apothecaries, Mr. Tweedy, the president of the Royal College of Surgeons, in responding for that body, claimed that it would meet any test of efficiency that could be applied. The statistics of the last ten years, he said, showed that the number of students entering the profession in England is declining, and he believes that it will continue to decline. In accordance with the promptings of the general medical council the standard of general education of students has been raised and the multiplicity and severity of the examinations has been increased. He would like to see the wheel turned back a little. Too much is being attempted in the way of examinations. He desires to see steps taken in the direction of simplifications without any sacrifice of efficiency. If some of the restrictions and regulations are relaxed he believes that a better practitioner than is possible under the present conditions would be produced. The student is overtaught and overexamined, so that he has no time to reflect, and to exercise his reason and intellect. The whole system, Mr. Tweedy said, is one of rush and cram. The Society of Apothecaries and the Royal College of Physicians and Surgeons have done their best to resist this encroachment and the mushroom-like growth of universities throughout the land. He believes that medical examinations are best entrusted to professional corporations.

The Prevention of Consumption.

A remarkable meeting at which all classes from the royal family to workmen were represented has been held in support of the scheme to provide sanatorium treatment for the working classes. The Princess Christian of Schleswig-Holstein, president of the national association for the establishment and maintenance of sanatoria for workers suffering from tuberculosis, represented the royal family; representatives of both houses of parliament, a bishop, municipal authorities, and hundreds of labor delegates and members of friendly societies and trade unions, many of whom wore their insignia of office, filled the body of the hall. It was announced that a sanatorium of not too expensive a character was being erected in Kent, where 250 acres of land had been acquired. On the grounds were two farms, where cured consumptives could gradually be trained to resume work. It was pointed out by one speaker that it would be more economic for the friendly societies to prevent and to cure the disease than to take the consequences of it and to pay sick allowances and funeral expenses.

The Dangers of Anthrax.

The danger of working among camel's hair and "low foreign wools" is shown by a case which recently occurred at Bradford. A coroner's jury returned a verdict of death from anthrax of a woman who had been employed as a finisher on camel's hair and low foreign wools. The inquiry showed that though these materials had been "sorted, washed, willowed, carded and combed," the anthrax bacilli had not been removed nor had they lost their vitality. Something more, therefore, should have been done before those working among them could do so safely.

Japan and Medical Practice.

At the meeting of the general medical council Dr. MacAlister, the president, stated that a communication had been received from the government stating that application had been made to his majesty on behalf of the Japanese government, requesting that Japan might be recognized as one of the countries to which the medical act of 1886 applies, thus enabling Japanese doctors to practice in the Straits Settlements as well as in other parts of the British empire. Inquiries have been instituted for the purpose of ascertaining the conditions under which British practitioners are permitted to practice in Japan; should these prove satisfactory and should an order in council be sanctioned, it will fall to the general medical council to consider what medical diplomas granted in Japan shall be recognized for registration in Great Britain.

A Mysterious Epidemic.

At the conference of health officers for London and the neighboring counties Dr. Freemantle, health officer for Hertfordshire, *reported that an epidemic* simulating cerebrospinal meningitis was first brought to the attention of health officers last January, when several persons, often of the same family, were attacked by a disease presenting symptoms, sometimes resembling those of scarlet fever, sometimes of tuberculosis, sometimes of meningitis, sometimes of influenza, and sometimes of cerebrospinal meningitis. Notes were obtained of 162 cases treated dating back to August, 1904, of which 16 were fatal.

Pharmacology

What Are "Proprietary" Medicines?

There seems to be a decided misunderstanding of the meaning of the term "proprietary" medicine, and before condemning one should realize what this term "proprietary" means. If all proprietary medicines are to be condemned, then the Council on Pharmacy *and* Chemistry has no cause for existence, for its work is to examine and to pass on such articles.

Proprietary medicines are those which some one owns; those that are the property of some one. Their ownership or proprietorship is held in two ways: (1) By a patent, or (2) by a trade or copyright name.

1. Patented Medicines. A patented medicine is one on which a patent has been granted. This requires that a full description of the article be filed with the Government, which description can be obtained by anyone for 5 cents by writing to the Patent Office. These are non-secret (patent means open); and the protection lasts for seventeen years. Some of our better preparations were patented, such as antipyrin, sulphonal, lanolin, but the patents have now expired. So long as the patents were in force these preparations were "proprietary medicines." Phenacetin is patented, the patent expiring next March. Until then it will be a "proprietary medicine." Alphozone, acetozone, thiocol, creosotol and other well-known remedies are patented medicines, and therefore proprietary. There is no objection to them, if they are advertised and marketed in an honest way.

2. Copyrighted or Trade-Named Articles. The vast majority of the preparations on the market in this country come *in this class.* They are proprietary in that the name given them is owned and controlled by some one. The name is the thing in this case. Nearly, but not quite, all the preparations that are sold under trade names *are to be condemned* because the composition is secret in character. If the composition is known, and if the remedies are honestly exploited, they are *not* necessarily to be condemned. One serious objection applies to all copyrighted or trade-names—they are a perpetual monopoly. A patented article becomes public property after seventeen years, but a trade-named article never does.

"Patent medicines" come in this class, the term being used to designate those advertised and sold directly to the public. The name, of course, is a misnomer, for they are not patented medicines. We suggest that the words "patent medicines" be always placed in quotation marks when the proprietaries advertised to the public are meant, so that there may be no misunderstanding. The word "nostrum" means "A medicine, the ingredients of which are kept secret for the purpose of restricting the profits of sale to the inventor or proprietor."—Webster. Hence, all proprietary medicines which are in any way secret come under this category.

Medical Literature "Made in Germany."

Some weeks ago[1] we called attention to a petition that was being circulated among the members of the profession of Germany as a protest against paid write-ups. The following abstract of matter taken from one of our German exchanges refers to the same subject and emphasizes what has been charged for some time, i. e., that paid write-ups are being published in German journals to be re-copied in this country. There seems to have developed the impression that anything "made in Germany" must be all right. The number and variety of mixtures that are simply nostrums that are being imported from Germany, and from France for that matter, should put physicians of this country on their guard, and especially against accepting as truth everything that is published in German journals or because the Germans said it. In the *Zeitft. f. aertzl. Fortbildung,* No. 17, is an article on the subject that should make interesting reading at the present time:

The petition cites as a typical example of the evil, the medical write-ups published on behalf of ———, stating that not only the manufacturers themselves, but their American agent ("an American journalist") have paid out hundreds of dollars for favorable articles on this new product, written by physicians who were not in a position to form a decisive judgment in regard to the curative value of the remedy. A letter from the American agent to a Berlin specialist and his reply are quoted, the condition of "strict secrecy" being explicitly demanded by the latter. The sum asked and paid was 2,000 marks ($500). For other write-ups the manufacturers or their agent have paid out sums ranging from 1,000 to 4,000 marks ($250 to $1,000). These investments have proved profitable, as a purchaser has been found in America who has signed a contract for a large sum—$125,000 it is rumored. An editorial in the *Zeitft. f. aertzl Fortbildung,* No. 17, quotes the above from *Die Post,* with the comment that the medical chambers (Aerztekammer) have too little jurisdiction in such matters to arrest these practices arbitrarily. They will stop only when the medical profession as a whole resolve to repudiate and to expose such practices as extremely injurious to the reputation of the profession, and does everything in its power to combat them. In a later issue, No. 19, the *Zeitft.* states further that the manufacturers of ——— have since written to *Die Post* publicly disclaiming all responsibility for the actions of their American agent. His business affairs are entirely independent, they say, of the business of the home office, and are not under the control of the latter. Consequently, they can not be held responsible for the means he has adopted to further his business aims. The editorial comments that this explanation does not alter the aspect of the case, as the home office has not repudiated nor dismissed the American agent.

Kansas Against Nostrums.

At its last meeting the Kansas State Medical Society adopted the following resolution, which was offered by Dr. W. H. Graves:

> *Resolved,* That the council of the Kansas Medical Society endorse the action of the national organization in refusing to insert advertisements of secret preparations, and recommend to the editor of the *Journal of the Kansas State Medical Society* that, as fast as present contracts expire, space be refused to such secret preparations.

This resolution was discussed by all present and was adopted unanimously.

Work of Council Indorsed.

The following resolutions were adopted at the December meeting of the Will County (Illinois) Medical Society:

> *Resolved,* That the Will County Medical Society expresses approval of the action of the American Medical Association in establishing the council on Pharmacy and Chemistry.
>
> That this society indorses the work of investigating non-official drugs and medicinal preparations.
>
> That the society gives its hearty support to the educational campaign regarding secret nostrums and commends the good work of The Journal of the American Medical Association.
>
> F. C. Fisher, Secretary.

At the regular meeting of the *Fort Wayne* Medical Society (the Medical Society of Allen County), December 5, the following resolution, presented by Dr. M. F. Porter, was passed:

> *Resolved,* That the *Fort* Wayne Medical Society approves of the appointment of the Council on Pharmacy by the American Medical Association, and of the efforts the members of this council are making to rid the country of those [illegible] and their products, which, while sailing under [illegible] really doing a business alike disgraceful and [illegible] also commends the editor of The Journal of [illegible] Association in the vigorous assistance he is gi[illegible] council.

Resolutions Regarding Dr. Billings' Paper.

Albuquerque, N. M., Dec. 7, 1905.

To the Editor:—I forward herewith a copy of the resolutions passed at the last meeting of the Bernalillo County Medical Society and request that you bring them to the attention of

---

1. The Journal, October 21, p. 1264.

the profession through THE JOURNAL with the view of securing some concerted action. W. W. SPARGO, M.D.

WHEREAS: Dr. Frank Billings, of Chicago, read before the Portland meeting of the American Medical Association an article entitled "Nostrums," which was printed in THE JOURNAL of the American Medical Association, a publication owned by the medical profession, and for the use and information

WHEREAS: One at least of the a compound drug and offering it to the profession and public under a copyrighted name, not representing the ingredients, has threatened the journals issued by the various state societies with suits for libel if the said journals reprinted Dr. Billings' article; and

WHEREAS: Many of these corporations alluded to in Dr. Billings' article have banded themselves together under a distinctive name and are commonly accredited with controlling many of the medical journals published, but not including those owned by the State Societies; and.

WHEREAS: There are many manufacturing drug companies who are willing and do publish the ingredients of their manufactured articles; therefore, be it

Resolved, That the members of the Bernalillo County Medical Society, feeling that as physicians they have a right to know the composition of all drugs used by them, refrain hereafter from using such articles as do not contain on the label attached the ingredients of which they are composed; and that they dispense or prescribe the products of such houses as comply with the above requirement; and,

Resolved, That the members of said society deny the right of any drug manufacturing concern to prevent any legitimate investigation into the composition of their manufactured articles; and that the Board of Trustees of the American Medical Association shall be requested by the secretary of this society to take such steps as shall lead to a concerted action of the medical profession, calling on the government and congress to enact such laws as will make impartial analyses of such articles compulsory; and,

Resolved, That the said society will co-operate with the state society in maintaining the right of the journal of this state society to publish any legitimate professional information; and be it further

Resolved, That a copy of these resolutions be forwarded to THE JOURNAL of the American Medical Association, be published in the *Journal of the Medical Society of New Mexico,* and also be furnished to the retail druggists of this city.

DUFFY'S PURE MALT WHISKEY.

Fraudulent Testimonials.

We have repeatedly asserted that there is no dividing line between nostrums advertised to the public in newspapers—"patent medicines"—and those advertised to the medical profession—"proprietaries." Many are advertised both to the public and to the profession openly—because there are medical journals that will take such advertisements. It is not our intention to expose the fraudulent character of so-called "patent medicines" except incidentally, until the fraudulent character of the "ethical" proprietary business has been published to the profession. We refer to Duffy's Pure Malt Whiskey this week because it is among the nostrums advertised to physicians.

We know of no more fraudulent and extravagant claims for any "patent medicine" than those which the proprietors of Duffy's Pure Malt Whiskey make in their advertisements. Their claims for it as a health restorer equal those made for peruna, liquozone, wine of cardui and similar nostrums.

But "Duffy's Pure Malt Whiskey" is advertised in medical journals!

A Sample Testimonial.

Some months ago a big display advertisement of Duffy's appeared in the newspapers. It was accompanied by a photograph of an old lady and by the old lady's testimonial. Here is the testimonial, with some of the comments on it that appeared in the "ad.":

"A DEAR OLD SOUL ACTIVE AND HAPPY AT 106.

"Mrs. Nancy Tigue, of Lafayette, Ind., Although in Her 106th Year, Says:

"'I Really Don't Feel Like I'm a Day Over 60, Thanks to Duffy's Pure Malt Whiskey, Which Is the Real Secret of My Great Age, Health, Vigor and Content.'

"Mrs. Tigue Is Blessed with All Her Faculties and Does Exquisite Fancy Work Without Glasses. She is as Spry as Many Women Half Her Age.

"With the Help of the Invigorating and Life-Giving Powers of This Wonderful Medicine Mrs. Tigue says She Expects to Live Twenty-five Years Longer.

"'I will be one hundred and six years old,' writes Mrs. Tigue, "on the fifteenth of March, and really I don't feel like I am a day over sixty, thanks to Duffy's Pure Malt Whiskey. Friends say I look younger and stronger than I did 30 years ago. I have always enjoyed health and been able to eat and sleep well, though I have been a hard worker. Even now I wait on myself and am busy on a pretty piece of fancy work. My sight is so good I don't even use glasses. Am still blest with all my faculties. The real secret of my great age, health, vigor and content is the fact that for many years I have taken regularly a little Duffy's Pure Malt Whiskey, and it has been my only medicine. It's wonderful how quickly it revives and keeps up one's strength and spirits. I am certain I'd have died long ago had it not been for my faithful old friend 'Duffy's,' August 10, 1904.'

"Duffy's Pure Malt Whiskey
"Is the Comfort and Support of Old Age.

"The sincere and grateful tribute of Mrs. Tigue to the invigorating and life-prolonging powers of Duffy's Pure Malt Whiskey is one of the most remarkable and convincing on record. She sews, reads and is dependent upon no one for the little services and attentions of old age. Mrs. Tigue's memory is perfect, and her eyes sparkle with interest as she quaintly recalls events that have gone down into history of the past hundred years. Instead of pining, as many women half her age, she is firm in the belief that with the comforting and strengthening assistance of Duffy's Pure Malt Whiskey she will live another quarter of a century."

These statements were so remarkable that we wrote to two physicians of Lafayette for facts. It seems that one of the Indianapolis newspapers published an item regarding Mrs. Tigue having reached her one hundred and fifth birthday, and evidently this was the cue for the Duffy exploiters.

The following letter is from Dr. George F. Keiper, one of the councilors of the Indiana State Medical Association. As the eye and ear surgeon to St. Elizabeth Hospital he visited that institution every day, which explains his personal knowledge of the case.

LAFAYETTE, IND., NOV. 18, 1905.

My Dear Doctor:—Yours of the 14th has been received; also a copy of an advertisemer newspapers last winter, which contains, among tograph of Mrs. Nancy Tigue, and also, amon the following: "Mrs. Nancy Tigue, of Lafayette, Ind. Although in Her 106th Year, Says: 'I Really Don't Feel Like I'm a Day Over 60, Thanks to Duffy's Pure Malt Whiskey, Which is the Real Secret of My Great Age, Health, Vigor and Content.'".

I have had several interviews concerning Mrs. Tigue and this testimonial. I have known the old lady for a number of years and, to my certain knowledge, she has never used alcoholics in any form. I used to see her every day at St. Elizabeth's Hospital. I interviewed Sister Bernardi, the Sister Superior of St. Elizabeth's Hospital, where Mrs. Tigue was for a number of years. The Sister Superior says that Mrs. Tigue never took any whiskey while there. I further asked Sister Benigna and Sister Aloysia and they both denied that she used Duffy's Malt Whiskey.

For the past three or four years Mrs. Tigue has been at St. Anthony's Home for the Aged, going there from St. Elizabeth's Hospital when the Home was opened. This Home is a branch of St. Elizabeth's Hospital. Sister Frances is in charge of the Home, and she told me that Mrs. Tigue has never taken a drop of any kind of whiskey while there.

I also saw her son, Mr. Michael Tigue. The advertisement of Duffy's Malt Whiskey filled him with indignation passing all bounds. He corroborated all that the Sisters told me, and he further told me that when this advertisement appeared, he had some sharp correspondence with the Duffy people.

The photograph used in the advertisement was obtained by a party who said he wanted to use it in one of the Indianapolis papers. *Of course, misrepresentation was resorted to.*

Concerning the testimonial: The man who obtained it, went to Mrs. Tigue and requested her to sign a testimonial concerning Duffy's Malt Whiskey, but she said she never used it, and the agent was told to see her son. The man then saw Mr. Michael Tigue, who refused to grant his request. The agent then took a notary public to the Home and represented to Mrs. Tigue that her son told her to sign the testimonial. Very truly yours,

GEORGE F. KEIPER.

Dr. W. W. Vinnedge is another Lafayette physician to whom we wrote. His letter we quote:

LAFAYETTE, NOV. 21, 1905.

Dear Doctor:—In response to your inquiries as to Mrs. Nancy Tigue of Lafayette, I beg to say that I investigated her case as to Duffy's Malt Whiskey somewhat less than a year ago. . . . This morning I found Mr. Michael Tigue, single, stone-cutter, ex-township trustee, 58 years old, son of Mrs. Nancy Tigue, and . . . he dictated and signed the enclosed statement. . . . You have been misinformed in one particular, Mrs. Tigue does not live in a home for feeble-minded, but in the Old People's Home, under the care of the Poor Franciscan Sisters. I visited her there twice in the early part of the past summer, saw her sitting by her bed fully dressed, saw her led across the floor by a Sister with a hand under her (Mrs. T's.) elbow, and she appeared to be nearly blind, as the Sister said. The old lady, however, is fairly intelligent, and while very senile in appearance talked understandingly. She and the Sister assured me that she drank no intoxicating drinks at all, and never had done so, and from their manner and words I saw that they thought the report ridiculous. I am sure that the old lady knows nothing at all about Duffy's Malt Whiskey.

As to the testimonial given by the old lady. About a year ago a young man from Indianapolis, a newspaper man, got off the train here one morning and called on Mr. Mike Tigue, and asked for a testimonial. Mr. Tigue gave him permission to see his mother, but refused the testimonial. The enterprising young man hired a horse and buggy from a livery stable, and taking Mr. Oscar Campbell, notary, Lafayette, drove out to the Old People's Home, about two miles, and saw the old lady, led her to think that her son Michael had sent them, that he wished her to sign the testimonial, which she did by making her mark, and without having a clear idea of the contents of her statement, and without having any idea at all of what use was to be made of it. You know the balance.

Later, as I am informed, Mr. Michael Tigue wrote, or caused his attorneys, Messrs. Kumler & Gaylord, Lafayette, Ind., to write to the Duffy Malt Company protesting against the use of his mother's name, forbidding it. Finally, he told me to-day, the firm quit publishing her picture and statement in the newspapers, but it is in press and will appear in Duffy's book soon; they could not "cut it out" of that at this stage. If you wish any additional information and will indicate what it is. I will be very pleased to try to get it and to help along the good work in which you are engaged.

Very truly yours,
W. W. VINNEDGE.

The following is the statement referred to, made by Mr. Tigue:

Lafayette, Nov. 21, 1905.

To Whom it May Concern:—I am the son of Mrs. Nancy Tigue, who is now an inmate of the St. Anthony's Home, and I am 58 years old. My mother is one hundred and five years old, was born in Ireland. Our home is, or was, 413 S. 1st St., Lafayette. Mother is almost blind, and she has been cared for by the Sisters about four years—one year at the Old People's Home. My mother never drank any intoxicating drinks at all. She does not know what Duffy's Malt Whiskey is. She was imposed on in order to obtain the advertisement of Duffy's Malt Whiskey, being nearly blind was influenced to sign a false affidavit by Duffy's solicitor, which was published without our knowledge or consent. Michael G. Tigue.

Still Duffy's Malt Whiskey must be "ethical," for is it not advertised in reputable medical journals!!

Centenarian Feels Like a Girl.

A "companion piece" to the above is the picture and testimonial of Mrs. Louisa Cox of Harrington, Maine. This is still appearing in the newspapers, or was a month ago. Here is the testimonial as it appeared in the newspapers:

"Harrington, Me., May 20, 1904.

"*Gentlemen:*—I am 105 years old. I am well, without a pain or ache. I sleep as well as I did when I was a girl. I use your whiskey and like it very much. Duffy's Pure Malt Whiskey is the only medicine I use. I get water from the well, bring in wood, and do my housework. Mrs. Louisa Cox."

The advertisement is accompanied with the usual extravagant claims and statement, but we have only space for one quotation. In this advertisement we are told that:

"There are 4,000 men and women in this country alone who have passed the hundred year mark, and nearly every one of them has publicly acknowledged that he or she owes health, *strength*, continued use of all the faculties, and extreme old age to Duffy's Pure Malt Whiskey, the great cure and preventive of disease, the true elixir of life."

Four thousand people in this country over 100 years old have publicly acknowledged that they use Duffy's Malt Whiskey!! Think of this statement and then realize that Duffy's Malt Whisky must be an "ethical" preparation, for is it not advertised in reputable medical journals?

We wrote to Dr. E. A. White, Columbus Falls, Maine, and asked him to investigate the case. Dr. White replies as follows:

Columbia Falls, Me., Nov. 11, 1905.

Dear Doctor:—In accordance with your request I went to the home of Mrs. Lovisa Cox (not Louisa as appears in the advertisement). She tells me she will be 107 the 12th of January, 1906. She says she never took Duffy's Pure Malt Whiskey or any other whiskey in her life. Never took but very little medicine any way. Her daughter, Eliza A. Shaw, with whom the old lady lives verified the statement. You will notice a statement from her on the back of your enclosed yetter. She knows about the advertisement which has appeared in the *Bangor Commercial*, a paper printed in Bangor, Maine. She has been interviewed a number of times about the matter and always denied it. Calls it a lie. The advertisement is in the *Bangor Commercial* now, same as the one you sent me. An article came out in the *Bangor News*, another paper printed in Bangor, Maine, denying the statement of the old lady's appearing in ad. of the *Commercial*. The old lady can neither read nor write, so if she made her cross (x) under any statement she would have no way of knowing really what it contained, thereby giving some unscrupulous person a chance to deceive her. I do not think this was even done. I do not charge you anything for my trouble; am only too glad to help you to unearth such frauds. Let me know if you need anything more. Yours, E. A. White.

On the back of the letter to Dr. White is written with pencil the following:

This is to certify that I, Eliza A. Shaw, daughter of Mrs. Lovisa Cox, know that my *mother never* has taken Duffy's Pure Malt Whiskey, or any other whiskey for medicine.

Witness: Susie A. Shaw. Eliza A. Shaw.

A letter to the postmaster of Harrington, Maine, brought the following reply:

Harrington, Me., Nov. 13, 1905.

Dear Sir:—Relative to enclosed ad. would say that party in question has never used liquor in *any form* and can secure her affidavit to that effect if you care to bear the expense. Party lives some four miles from town: it would be necessary to drive out in order to interview her. Yours, Wm. N. Dyer, P. M.

Those who want further information regarding the character of the Duffy testimonials should refer to the article in *Collier's Weekly*.

For the wonderful virtues of Duffy's Malt Whiskey, as a medicine, we respectfully refer to the advertisements appearing in the newspapers of the country.

The advertisement of Duffy's Malt Whiskey is appearing in some well-thought-of medical publications. Would it not be well for those physicians who are subscribing to and supporting such publications to write to the publishers regarding this insult to their intelligence? Of course, the cancellation of a few subscriptions does not compare with the amount received from a several hundred dollar advertising contract, and the publishers who have only the financial end in view will not be materially impressed at first. Still, every little counts, and if the profession will take up this matter it will surely have some effect at least.

Correspondence

Fees for Life Insurance Examinations.

Skippack, Pa., Nov. 29, 1905.

To the Editor:—In the light of and with the knowledge daily brought before us of "high financiering" as exemplified in the old-line life insurance companies of New York, with more to come, it would seem that any physician who makes an examination for a fee of three dollars or less is, to say the least, "easy." Some men have refused to examine an applicant for such a fee, only to be sarcastically informed by the agent that there were "others," not only waiting but anxious. Unfortunately he was telling the truth. We are cheap. Medical societies should take this matter up.

J. Newton Hunsberger.

The Burning of the Books.

Chicago, Nov. 24, 1905.

To the Editor:—No species of vandalism has ever aroused such universal execration as the wanton destruction of literature and records, whether accumulated for that purpose or captured with other acquisitions of victory. In modern times the easy production and multiplication of books has brought the dignity and presumptive value of the book to a low ebb; and, while the ancient tome had, from its very existence, a modicum of permanent value, the book of to-day may be valueless and a mere incumbrance, either because of its primary inherent worthlessness, or its worthlessness in a particular form, or on account of the enormous edition, or an edition made incomplete by abridgement, by faulty translation, by reproduction on poor paper, in bad print or with other defects. To the bibliophile any book within his horizon has a certain bibliographic, literary and commercial value, based on fluctuating interest and fluctuating supply and demand. To the student a book is valuable for the data or the literature which it contains. To the antiquarian and second-hand book dealer a book is worth just so much as he can get for it. To the paper maker all books are valued by the pound or ton.

In modern times the great public library has come to be a hopper, into which the private libraries of declining families, dissolving households and defunct societies naturally tend, and as a result the store rooms of the principal libraries are flooded with an unsorted mass of books, magazines and manuscripts. The value of these contributions is not great, yet each wagon load contains a few volumes desirable for exchange and one or two worth binding and preservation, and every few months a rare book is added to the archives of history.

We may almost condone the affront which is offered our regard for the book when the management of these great libraries stealthily and covertly disposes of carloads of material to the paper maker.

A now prominent scholar and author who, thirty years ago, published a masterful reflection of his instructor's theories and conceptions in a handsome book has, during the past twenty years, gradually bought up and consumed in his furnace and fireplace every obtainable copy. He has slowly raised its price from two cents a pound to twenty-eight dollars and a half a copy, and from taxing the capacity of his furnace with the annual consumption he now has scanty material for folded lamplighters on his mantelpiece. We may doubt whether the silent influence of the printed page, even of the full edition, was as subverting to public morals as the active bid of the increasing price is to systematic larceny from library shelves.

In spite of the aggravation to which the baited librarian and sometimes the unhappy author yield, it is painful for us to see the printed page consumed. We turn away from the bonfire and the paper mill with a pang and look on the ruffled books stripped of their covers with regret. Nevertheless there is a book which deserves this fate. It merits the worst form of destruction; its pernicious influence is more deadly than all the bacteria and contagion which its greasy covers and soiled pages can harbor. It deals death and gives complacency to the widespread destruction of adults, youths and infants. There are few epidemics that destroy as many as the endemic of this dirty book. If the boards of health are called on to arrest epidemics; if they may use police power to abate nuisances destructive of health or life, this power and this function ought to be called in play to exterminate this death-dealing book.

The antiquated text-book of medicine is a positive and widespread danger to society. It perpetuates and makes active the baleful influence of our medical forbears. This influence is greater the greater the authority and the more permanent the position of the author. If a man has done his work before he is 50 and ought then to step aside and give place to the young, the medical text-book has outlived its usefulness in one-tenth that time. The libraries of sixty thousand physicians are encumbered, their practices vitiated and their patients put to unnecessary suffering and danger by the sixty thousand antiquated Oslers. How boldly the vanquished physician standing at the bedside of his unfortunate patient quotes, to his complacency and the palliation of his defeat, the dictum of an Osler of the edition of 1894, and with what humility, not to say astonishment, would he read the reversal of that opinion in the last edition! The antiquated textbooks of medicine of ten years ago, especially those that treat of the care of infants and the treatment of genito-urinary diseases and general medicine, are now supporting the pernicious practices of an army of physicians, in whose hands they cause uncalled-for and immeasurable suffering and no small mortality. These old books, however, maintain an unquestioned dignity and respectability, while the automobile and cigarette call forth columns of malignant abuse, interminable persecution and drastic legislation. Single lines have been followed by a weeping and limping procession, which the repeated recantation of the author in subsequent editions and the earnest and dramatic teaching in class room, lecture hall and journal has been unable to arrest. The curse of modern medical book selling is the antiquated text-book. The book agent foists his wares on the indulgent physician who scarcely turns in his last payment on a good book before it is superceded by another edition made necessary by the rapid advance in medical diagnosis and treatment. Since we have referred to Osler, let us take as illustrations the diagnosis and treatment of any of the diseases of the abdominal viscera in the last edition and the edition of ten years ago. Could there be a greater contrast between the teachings of any medical sect and that of rational medicine than between Osler's own account of the non-malignant diseases of the stomach, the diseases of the biliary apparatus, dysentery and appendicitis[1] in these two editions? Nevertheless we hear the Osler of ten years ago quoted ex cathedra in every medical society and often at the bedside with no appreciation of its melancholy import. Should an attorney quote the decision of a court which had for ten years been reversed, he would be sharply corrected by the opposing counsel. The patient's advocate, the physician, meets, unfortunately, a silent plaintiff in a court of unquestioned justice. When he meets defeat he departs, often unconscious of his remissions, and even the autopsy fails by its rarity and novelty to jolt the complacent and luck-trusting practitioner into the serious consideration of the rapid advance of his art.

104 East Fortieth Street. Bayard Holmes, M.D.

Acetozone Solutions.

New Haven, Conn., Dec. 3, 1905.

To the Editor:—I am anxious to learn if any one else has had any experience in the use of acetozone solutions for injection into the spinal canal after lumbar puncture in cerebrospinal meningitis. I have used it recently with apparently good results in two severe and protracted cases. In both these cases puncture had already been required to relieve urgent pressure symptoms, but, while successful in this respect, the procedure had been without effect on the temperature. After the acetozone injections this remained nearly normal. A weak solution (5 grains to quart) was used, the patients being aged 7 and 4 respectively. In the first case 30 c.c. of fluid were withdrawn and 15 c.c. of the acetozone solution injected; in the second case 35 c.c. were withdrawn and 15 c.c. injected. In the acute fulminating cases, in which death takes place before the formation of much fluid, such injection would be difficult and probably ineffectual. Probably stronger solutions can be used. Louis S. De Forest.

Is the Bituminous Coal Miner Immune from Tubercular Infection While Actively Engaged in His Occupation?

DuQuoin, Ill., Nov. 21, 1905.

To the Editor:—After an experience of 25 years in one of the largest coal mining towns in southern Illinois, and during this time having under my observation from 700 to 1,200 coal miners; and after careful enquiry among the oldest miners in this locality as to the number of coal miners that have been infected with this dreadful disease, I have been forced to the conclusion that bituminous coal miners, while actively engaged in their occupation, are practically immune from tubercular infection.

About seven years ago I commenced the treatment of whooping cough by sending the patient down in the mines immediately after the miners had fired a shot; having the patient inhale the gas and powder smoke for one and a half to two hours at a time. I found that one or two sittings was sufficient to effect a cure in from four to six days, and without other medicine.

This was followed up until I have on my records from 75 to 100 cases, ranging in age from 3 months to 27 years. This treatment has passed so far as my experience goes, from the experimental stage to the stage of confirmation. It is so successful and is now so well known in this locality, the miners take their children so affected into the mines, without consulting a physician, and always with the happiest results.

In June, 1905, I obtained from the coal operators "Blue Book," and from a United States medical directory the addresses of 600 physicians practicing in the coal mining towns of Illinois, Indiana, Ohio, Pennsylvania and West Virginia. I carefully selected the names of those who had practiced not less than 10 years, and sent to them a circular letter containing four questions, and enclosing with each a stamped, addressed envelope for reply, in order that I might gather from their experience some statistics on the liability of coal miners to tubercular infection, while actively engaged in their occupation. The following is the text of the body of the letter and the four questions:

> *Dear Doctor:*—In order to obtain statistical information from those of my professional brothers who can speak from experience and observation concerning the frequency and liability of infectious tuberculosis among coal miners as a class, I respectfully submit the following questions:
>
> 1. How much professional experience have you had among coal miners?
> 2. About what per cent. of all coal miners who have come under your professional observation have had infectious tuberculosis?
> 3. About what per cent. of those who, of your own knowledge, had been exposed to tuberculosis have been infected?
> 4. Taking into consideration their usual habits of life, together with their daily exposure, do you consider coal miners, as a class, immune from tubercular infection while actively engaged in their occupation?

As a result of these inquiries I have thus far received in reply over two hundred letters. Of this number about 75 per cent. give as their experience and observation, that during active service in his occupation the bituminous coal miner is immune, wholly or in part. M. C. Carr, M.D.

The Psychopathic Manifestations of the Non-Insane Psychoneuroses.

New York, Dec. 8, 1905.

To the Editor:—In the valuable article under the above title in The Journal, December 2, Dr. John Punton makes some timely remarks on inexact nomenclature. I wish to add some suggestions: As physicians giving the word in our own language, we say disease of the mind and not disease of the soul; German physicians say *Geisteskrankheit*, which is also distinctly disease of the mind in distinction from *Seelenkrankheit*, disease of the soul; the French say likewise disease of the mind, namely, *frénésie*, and not disease of the soul, which would be *maladie de l'âme*, and the Greeks, like Frenchmen and Germans, in their own language call it phrenopathia, when they mean the medical term, not psychopathia; they do not say psychocomion, but phrenocomion for lunatic asylum. At this occasion no criticism is intended, but only statement of facts. Another fact is that psychosis in Greek means animation, infatuation, inspiration, but never mental derangement; the correct word for alienation of the mind is phrenitis, an excellent term. It is to be assumed that everybody knows by this time that the suffix "itis" does not necessarily mean inflammation. Phrenitis means distinctly a morbid affection of the mind. The new term suggested by Dr. Punton, "psychosomatasthenia," is rather Lexicon-Greek; phrenosomatitis would express the same meaning, but I would not dare to offer it for adoption before consulting Greek friends, if it would be acceptable. A. Rose.

[1] "The medical treatment of appendicitis can be expressed in three words—rest, opium and enemata."

Marriages

David M. Rank, M.D., to Miss Susie F. Herr, both of Annville, Pa., November 28.

John Lehr, M.D., Lykens, Pa., to Miss Laura B. Hehring of Reading, Pa., November 29.

Raymond G. Olson, M.D., to Miss Charlotte E. Burke, both of Muskegon, Mich., December 4.

James S. Akehurst, M.D., Baltimore, to Miss Agnes Hance of Stewartsville, N. J., December 3.

Walter M. Bowers, M.D., Bassett, Iowa, to Miss Clara Belle Parks of Waterloo, Iowa, December 5.

Napoleon Bertrand Ross, M.D., to Miss Mary Agnes Loughlin, both of Sonyea, N. Y., December 2.

Harry C. Diltz, M.D., Wilkinsburg, Pa., to Miss Elsie Pamilla Smith of Derry, Pa., December 7.

Thomas D. Maher, M.D., San Francisco, to Miss Josephine Hannify of Sausalito, Cal., November 28.

Waldemar T. Richards, M.D., New Orleans, to Miss Jessie Ross Cotter of La Grange, Ga., December 13.

N. O. Pearce, M.D., Chisholm, Minn., to Miss Elizabeth Carlton Harden of Minneapolis, Minn., December 4.

Edgar Lee Craft, M.D., Sumrall, Miss., to Miss Mamie Amelia Royals of Meridian, Miss., November 15.

George M. Ingham, M.D., Milwaukee, Wis., to Miss Margaret Atwater of Iowa City, Iowa, November 29.

Williard B. Hyde, M.D., Christiansburg, Ohio, to Miss Leo Robinson, Lost Creek Township, at Piqua, Ohio.

Warren E. G. High, M.D., lieutenant (j. g.) U. S. Navy, to Miss Mary L. Knabb of Reading, Pa., December 5.

Arthur A. Pratte, M.D., Keene, N. H., to Miss Marie J. Belanger of Everett, Mass., in Boston, November 28.

Benjamin J. Edger, Jr., M.D., U. S. Army, to Miss Edith Downing of San Francisco, Cal., the last week in November.

Allen Monroe Ottman, M.D., Hilton, N. Y., to Miss Caroline Elizabeth Hatfield of New Hartford, N. Y., November 27.

Charles Hyde Davidson, M.D., Lexington, Va., to Miss Addie McChesney Brown of near Hebron Church, Va., November 22.

Herbert Charles Gibner, M.D., assistant surgeon, U. S. Army, to Miss Charlotte Elizabeth Bruce, at Wawona, Cal., November 30.

Deaths

Charles B. Schoolfield, M.D. Medical College of Ohio, Cincinnati, 1873, of Dayton, Ky.; state referee for Campbell County; president of the county board of health; first president of the Northern Kentucky Medical Society; president of the Campbell and Kenton County Medical Association, and president of the medical staff of Speers Hospital, Dayton, of which he had been a trustee since its opening, died at a hospital in Charleston, W. Va., from sciatica, after a long illness, aged 59. Resolutions of respect and sympathy have been adopted by the societies of which he was so long a member.

William Friend, M.D. Years of Practice, Illinois, 1877; a member of the American Medical Association, Illinois State Medical Society, and Lawrence and Wabash County medical societies, and several times president of the latter organization; for 47 years a practitioner in Lancaster, Ill.; from 1868 to 1872 a member of the State Board of Equalization, died at the home of his son in Sumner, Ill., December 4, from cerebral hemorrhage, aged 77.

John J. Walsh, M.D. University of Buffalo, Medical Department, 1871; a member of the county and state medical societies; some-time sanitary inspector of the Buffalo Department of Health; a member of the Board of Health, and secretary of the Alumni Association of the University of Buffalo Medical Department, died at his home in Buffalo, December 6, after a long illness, aged 57.

John S. Arwine, M.D. Medical College of Ohio, Cincinnati, 1853; member of the Bartholomew County (Ind.) Medical Society; some-time health officer of Columbus, and physician of Bartholomew County, died from heart disease at his home in Columbus, Ind., December 2, after an illness of one year, aged 81. The county medical society passed resolutions of respect and regret.

Herman Emanuel Muller, M.D. University of California Medical Department, San Francisco, 1880; a member of the American Medical Association, Medical Society of the State of California and Alameda County Medical Society; one of the most prominent practitioners of Oakland, Cal., died suddenly at his home in that city, December 2, from acute laryngitis, aged 47.

L. Rollin Hudelson, M.D. Jefferson Medical College, Philadelphia, 1896; a member of the American Medical Association, Indiana State Medical Society, and Rush County Medical Society, died at his home in Milroy, Ind., December 6, from appendicitis, after an illness of one week, aged 48.

Edson Davidge Royal, M.D. College of Physicians and Surgeons in the City of New York, 1904, an interne in the General Hospital, Paterson, N. J., died at his home in Lebanon, Conn., November 28, from valvular heart disease, after an illness of six months, aged 31.

William Perry Bennett, M.D. Ohio, 1877, for many years surgeon of the Pennsylvania Lines at Crestline, Ohio; a member of the American Association of Railway Surgeons, died in his office in Crestline, November 30, from morphin poisoning, aged 49.

Leonard M. B. Ferleman, M.D. Meletanic College of the Netherlands, 1864, of Ithaca, Mich., for many years surgeon on Atlantic liners, died suddenly from heart disease while making a professional call, November 30, aged 62.

Henry J. Thomas, M.D. Rush Medical College, Chicago, 1873, surgeon in the Army during the Spanish-American war, died at his home in Winston-Salem, N. C., November 29, from pneumonia, after an illness of one week, aged 55.

Wiliam J. Collins, M.D. Illinois Medical College, Chicago, 1903, of Geneva, Ind., was struck by a train and instantly killed while driving across the G. R. & I. R. R. tracks near Geneva, December 3, aged 39.

Edgar H. Whitten, M.D. Medical College of Alabama, Mobile, 1887, of Munford, Ala., fell from his buggy near that place, December 2, and was found dead in the road next morning, from cold and exposure.

Edward Osborn, M.D. College of Physicians and Surgeons in the City of New York, 1886, died at his home in East Hampton, Long Island, N. Y., December 4, from heart disease, aged 70.

Joseph Furniss, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1872, died suddenly at his home in Lancaster, Pa., December 8.

Benjamin F. Bronson, M.D. Pennsylvania, 1873, died at his home in Bridgeport, Conn., from cerebral hemorrhage, after an invalidism of three years, aged 54.

John Matheson, M.D. New York University, New York City, 1896, was robbed and murdered near his home in the Bronx, New York City, December 8, aged 38.

Francis Rowan Webb, M.D. Chicago Medical College, 1875, died at his home in Chicago, December 7, from pneumonia, after a short illness, aged 54.

Solomon B. Bowerman, M.D. Philadelphia, 1866, died at his home in Leaf River, Ill., November 27, from nephritis, after an illness of ten days, aged 77.

Joseph Berens, M.D. Pennsylvania, 1841, died at his home in Philadelphia from senile debility, after a short illness, December 6, aged 92.

George Kassen, M.D. Miami Medical College, Cincinnati, died at his home in Cincinnati, December 10, from cirrhosis of the liver.

Book Notices

Clinical Methods. A Guide to the Practical Study of Medicine. By R. Hutchison, M.D., F.R.C.P., and H. Rainy, M.A., F.R.C.P. Ninth Edition. Cloth. Pp. 634. Price, $2.50 net. Chicago: W. T. Keener & Co., 1905.

This American republication of the well-known English book only needs mention. The numerous editions through which it has already gone are sufficient evidence of its worth. Its full and apparently accurate description covers the whole field of physical and clinical diagnosis.

Atlas and Epitome of Diseases of the Skin. By Prof. Dr. Franz Mracek of Vienna. Edited with Additions, by Henry W. Stelwagon, M.D., Professor of Dermatology, Jefferson Medical College, Philadelphia. Second Edition, Revised, Enlarged and Entirely Reset. Pp. 272; 127 Illustrations, 77 in Colors. Cloth. Price, $4 net.

This work is improved in its second edition by many new illustrations and considerable revision to bring it up to date. The colored pictures are certainly very valuable. Illustrations of skin lesions without colors are of comparatively little use; the practitioner will find this work decidedly helpful.

Microtomist's Vade-Mecum. A hand-book of the Methods of Microscopic Anatomy. By A. B. Lee, Sixth Edition. Cloth. Pp. 358. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co., 1905.

This edition contains much new matter, but the text has been condensed considerably so that the size of the book is not increased appreciably. The old chapter on staining with the coal-tar colors is omitted, but its contents have been worked up into the chapter on staining, which has been rewritten entirely. This combination adds to the worth of the book. The chapters treating of the nervous system have undergone a most thorough revision so as to conform with the technic now employed for the microscopic study of these tissues. The new arrangement increases the value of the book as a guide to the laboratory worker.

Medical Diseases of Egypt. By F. M. Sandwith, M.D., F.R.C.P. Lecturer at the London School of Tropical Medicine. *Part I. Cloth. Pp. 316. London:* Henry Kimpton, 1905.

This is an interesting book, written by one who understands his subject. He not only writes as one who has mastered what has been written by others on the topics which he discusses, but adds much that is valuable from his personal experience. To us in America it is of interest as a contribution to the study of the distribution of commoner diseases and of tropical diseases in particular. The first chapter, if we are to make any criticism on it, is too brief. It is devoted to the history of medicine in Egypt from the earliest time to the present. It is extremely interesting and might easily have been extended with value to the reader.

Part first, which is all that is in our hands, is a volume of several hundred pages and covers many of the infectious diseases. Forty pages are devoted to typhoid fever, and many facts of interest are noted. Among them we note that in Egypt typhoid is most prevalent during January, February and March and not during the fall months, as is the case in temperate climates. The author also cites as evidence of a degree of immunity on the part of native Egyptians to this disease that Americans and Englishmen acquire the disease by drinking impure water, which is used constantly by the natives with apparent immunity. Several illustrations of this fact are cited. It would be interesting—and our author says nothing on this point—to know whether the fever occurs in modified form commonly in childhood among the Egyptians and thus confers immunity on the adult. Sixty pages are devoted to plague.

Ankylostomiasis is discussed fully and is a common disease in Egypt. The author points to the fact that Joachin and Schentbauer think that it was referred to and partly described in the Ebers Papyrus written 3,460 years ago. He also describes the observations of Dr. Looso on the early symptoms of this malady, which are those of ground itch, and to the experiments which show that the parasite gains access to the body through the skin, producing so-called ground itch. He also refers to the observations of Claude Smith, of this country, bearing on the same point.

This book can be heartily recommended to all who are interested in the geographical distribution of diseases and their varying manifestations under varying conditions of climate.

Ophthalmic Neuromyology. A Study of the Normal and Abnormal Actions of Ocular Muscles from the Brain Side of the Question. By G. C. Savage, M.D., with 51 Illustrations. Cloth. Pp. 221. Published by the author, Nashville, Tenn.

Any work on the oculomotor system by Dr. Savage must attract attention, as he is admitted by every ophthalmologist conversant with the literature of the day to be, perhaps, our highest authority on the subject. This, we are sure, is true not only of theories connected with eye muscle problems, but of their bearings in practice. Quite apart from his other works touching on these questions, "New Truths in Ophthalmology" and "Ophthalmic Myology" he has written many articles in which original views of the innervation of the straight muscles, their actions under normal and abnormal conditions, and their relations to one another are plainly set forth. Although it has not been possible for some observers to accept all these new doctrines, it must be said that the majority of them have successfully withstood the test of time, criticism and further investigation. Consequently, we are inclined to regard with favor the following propositions of Dr. Savage and to commend them and his book to the serious study of all earnest ophthalmologists and neurologists. These hypotheses (which after reading the work under consideration rise in our mind to the dignity of theories) form the basis and constitute the gist of the monograph:

"There are eight conjugate brain centers in the cortex, by means of which the several versions are effected, and one conjugate center by which convergence is caused. These conjugate centers act alike on orthophoric and heterophoric eyes and when there is only one eye. Each is connected with two muscles, and the work done by the center and its muscles under the guidance of volition, is normal work. The conjugate centers have no causal relationship with heterophoric conditions, nor have they any power to correct them.

"There are twelve basal centers, each connected with one muscle only. If the eyes are emmetropic-orthophoric these centers are at rest; in the presence of any form of heterophoria they are, during working hours, ever active. These centers do not produce heterophoria, but they stand ready to correct it. Under the guidance of the fusion faculty each basal center is prepared to act on its muscle, whenever there is a condition likely to cause diplopia. They may be called fusion centers."

Turning to the application of these hypotheses one finds that not only is no revolution in our well-known means for detection and treatment of muscle imbalance attempted, but these recent studies of the author rather emphasize that we, in America, generally accept as the best means of measuring and relieving the various forms of heterophoria and heterotropia. Of the many truths forcibly and clearly stated in Dr. Savage's monograph there is at least one that observing members of the profession will heartily applaud. It is that every man or woman who aspires to correct errors of refraction and of the oculomuscular balance should be "required to complete a graded course of study covering four years in a reputable medical college; for this work is as much a part of the practice of medicine, as is the treating of a case of pneumonia or the setting of a broken bone."

Miscellany

Glass Balls for Treatment of Trachoma and Pannus.—Likiernik writes from Lodz to the *Med. Klinik* for November 5 that he has obtained fine results in 310 cases of more or less chronic granular eye affections by local massage with a glass ball mounted on a long handle. The diameter of the ball is from 7 to 12 mm., and it is readily introduced under the upper or lower lid. After a few sittings the patient learns to use the ball himself. Diffuse granulations of years' standing yield rapidly to the daily use of the ball for merely thirty to sixty seconds, supplemented by the action of some antiseptic solution in which the ball is dipped before using. *Pannus*, if not too old, subsides quickly. Complications, such as infiltration of the cornea or indolent ulcers, do not contraindicate the ball treatment. Sometimes before using the ball he moistens it with a weak mercurial or 3 per cent. boric-acid solution.

Education Is the Cure.—The best weapon of the right is education. The best way to overcome quackery and public indifference is through education. Hence we believe that every high school and college should offer courses in domestic hygiene. Under that term we mean an explanation of the nature of disease and its causation, the conditions of health in the home and about town, simple nursing, the laws of cure, etc. This is, of course, along the line attempted by the school physiology work of recent legislation, but it is yet so different that the need is not met by the teaching of the elements of anatomy and physiology to children. The course should discuss all the more common diseases and the principles of treatment. It should include vaccination and serum treatment. In fact, it should be a popular course on the subject of rational medicine. Only thus can the man who has a cure-all be forestalled.—*Journal of the Kansas Medical Society.*

Sleeping Sickness in the Angola Highlands.—F. C. Wellman, in the *Journal of Tropical Medicine*, states that in the interior of Central and Southern Angola there is a distinct line of demarcation between the sleeping sickness districts and the regions free from that scourge. This line is the Coanza River. From the north bank of the Coanza to the northern boundary of the colony sleeping sickness is endemic in many situations; while from the south bank to German Southwest Africa it is not endemic, and, although one meets with occasional cases imported from the north, the disease does not spread nor attack the southern tribes. It is of great interest, he states, to note in this connection that north of the Coanza River the ordinary *Glossina palpalis* (so he has been informed), is the common tsetse-fly, while south of the Coanza the typical *G. palpalis* is not found, but its place is taken by the new subspecies, *G. palpalis wellmani*, recently described by Austen, which evidently is not a distributor of sleeping sickness. The exact relation between the geographical distribution of the disease and that of the two flies is a problem on which Wellman is now at work.

Hygiene in the Days of Good Queen Bess.—An interesting article describing the precautions taken in the reign of Queen Elizabeth to prevent the spread of plague and showing that even in the sixteenth century the value of isolation and disinfection was known and appreciated appears in the *Indian Medical Record*, Aug. 23, 1905. The regulations, etc., were published in a book, and the instructions to justices and the various rules are reproduced by the *Indian Medical Record* in full, with the quaint diction and spelling of those days. Houses of people sick with plague were required to be kept closed for a certain length of time, and if the owners of the infected houses did not observe this regulation they were imprisoned in the stocks and a sign put on the house. "And where any such houses shall be Innes or Ale houses, the signes shall be taken down for the time of restraint and some crosse or other marke set up in the place thereof, to be a token of the sicknesse." Certain persons were appointed to provide food and other supplies and to deliver them to the sick, and these persons, during their term of office, were required to carry a white rod in their hand or to wear some distinctive mark whereby other people might avoid them. A place was ordered set apart in every parish for the burial of those who died of the plague. The burial had to take place after sunset but before dark "so as the Curate be present for the observation of the rites and ceremonies prescribed by the lawe, foreseeing as much as conveniently he may, to be distant from the danger of infection of the person dead, or of the companie that shall bryng the corse to the grave." Bedding and other articles used by the sick were ordered to be "either burnt and cleane consumed with fire or else ayred." Poor people were recompensed for the destruction of their property. Any person preaching or publicly stating that precautions were vain and that a person dies at his appointed time was warned to desist, and if the warning was not heeded he was imprisoned. All justices in towns and villages were required to aid in carrying out these regulations. Taxes were imposed on the various towns and on wealthy people to defray expenses.

Decreasing Birth Rate in France.—Consul Haynes, of Rouen, in *Monthly Consular Reports*, says that there is no more worrying, persistent question in French economy than that of population. Nothing, he says, is so vexatious to the ambitious Frenchman than the fact that in Germany there are 600,000 more births annually than in France; and nothing more exasperating than the remark of von Moltke: "Every year by our birth rate we gain a battle over France." Mr. Haynes quotes statistics to show how this "nightmare of depopulation" has grown with every census in the last hundred years. In 1800 the population of Europe, in round numbers, was 98,000,000, of which 26,000,000 was French; thus France then had 26 per cent. of the population of Europe and now has only 11 per cent. At one time French was spoken all over the world; today it is the language of 45,000,000 people, while German is spoken by 100,000,000 and English by 150,000,000. Until 1850 France, in point of population, had been the first of the great European nations, afterward the second, but now the sixth, with Italy closely following and threatening to pass France and to leave her seventh. French statesmen realize the danger to their country and are asking what is to become of France, while bills intended to remedy the evil are being introduced into the legislature and societies are being formed all over the country. The National Alliance for Increasing the French Population was founded in 1896, its object being to point out the danger that threatens the country and to devise means to remedy it, and to secure appropriate legislation. The alliance states: France is on the way to become a third-class power; this tendency is due to the decreasing birth rate. It is as much a man's duty to contribute to the perpetuity of his country as to defend it in time of war. To bring up a child is a duty to the state equivalent to paying taxes. To acquit sufficiently this duty every family should have at least three children; therefore, families with more than three children should be exempt from taxation. The laws of inheritance and the present methods of dividing property should be modified, as the present laws are not conducive to large families. Lastly, infants should be protected in order to diminish the mortality of the new born. One of the causes of this comparative depopulation of France is said to be the neglect of religious practices and beliefs. Other causes are said to be military service and the inheritance laws by which all land goes to the eldest son, thus assuring him a position and competence. Paternal selfishness is given as another; many fathers who would have been able to live in ease if they had a limited number of children are compelled to labor arduously to provide for their families.

Queries and Minor Notes

ESPERANTO MANUAL.

NEW HAMPTON, N. H., Dec. 8, 1905.

To the Editor:—Will you kindly inform me through THE JOURNAL if there have been published a dictionary and a grammar of the artificial language Esperanto? If so, where are they procurable and what is the price?

A. S. DOLLOFF.

ANSWER.—A students' complete manual of Esperanto, with vocabulary, a book of 175 pages, by J. B. O'Connor, B.A., was published in 1903 by F. H. Revell & Co., Chicago. The price is $0.60. The dictionary costs $1, from the same firm. The Librarie Hachette, Paris, publishes the monthly in Esperanto called the *Internacia Scienca Rivuo*. The original grammar contains only sixteen rules, and there are no exceptions to any rule.

RECIPROCITY WITH WISCONSIN.

——, Dec. 1, 1905.

To the Editor:—1. What states have reciprocity with Wisconsin in the matter of recognizing, without examination, a license gained by examination in Wisconsin? 2. What other states, though having no established reciprocity with Wisconsin, recognize, without examination, a license earned by examination under the Wisconsin State Board?

X. Y. Z.

ANSWER.—1. Wisconsin reciprocates only with Indiana, Michigan, Ohio, Iowa, Kansas, Illinois, Nebraska, Kentucky, Maryland, Georgia, Oklahoma, South Carolina, New Mexico, North Dakota and District of Columbia, on the basis of qualifications as adopted by the American Confederation of Reciprocating Medical Examining and Licensing Boards. Requirements by the various states are so different that the question can not be answered by a general statement. Any physician desiring to register in another state should correspond directly with the secretary of the Licensing Board of that State. 2. None.

POLISH AND GERMAN CONVERSATIONAL AIDS.

Norwich, Conn., ———— —, 1905.

To the Editor:—I am often called to Polish families and am anxious to secure a small book containing Polish-English sentences, if you know of any such, or in fact any book by which one could be able to converse with them as a physician would like to. Similar simple books in German-English and French-English would be of service.

Charles F. Whitney, M.D.

Answer.—A series of small pamphlets, written by F. Thimm, is published by Dick & Fitzgerald, 18 Ann Street, New York, entitled "Self-taught German," "Self-taught French," "Self-taught Spanish" and "Self-taught Italian," containing brief conversations on various subjects, including one on the health. The pronunciation of each word is given so exactly as to aid greatly. There is no Polish pamphlet, but a very good Polish-German guide to conversation is published by B. Behr, Berlin. It has a large part devoted to "Conversation with the doctor." It is by F. Fischer, and copies are for sale by the Foreign Bookstore, Koelling & Klappenbach, 100 Randolph Street, Chicago, for 55 cents. There is no pronunciation in this manual, but any one able to pronounce German can make himself understood with the Polish sentences. "Medical German," by Deutsch, contains conversations with patients in German and English. Cloth. Price, $1.75.

Parallel reading of an article with a literal translation is a great help toward acquiring proficiency in a foreign language. Comparing the words and paragraphs, line by line, sentence by sentence, shows the structure of the foreign language, while the reader makes rapid progress without the bother of turning to the dictionary (see The Journal, July 22, 1905, page 253). Copies of a small semi-monthly for parallel readings in German and English have been received at this office. The *Translator* aims to supply short articles, stories, news items, business letters, puzzles, etc., in parallel columns of German and English text. A French and German number is also issued, called *Le Traducteur*, now in its thirteenth year. A specimen number will be forwarded free of charge on writing to the publisher of the *Translator*, La Chaux-de-Fonds, Switzerland. The subscription price is $1 a year, doubtless with something extra for foreign postage.

THE PERCENTAGE OF UREA IN URINE?

Los Angeles, Cal., Nov. 17, 1905.

To the Editor:—It is not an uncommon experience in reading articles in medical periodicals in which an analysis of the urine is given, to see it stated that the urine contained a certain percentage of urea, without giving any hint as to the amount of urine passed *per diem*, which gives no information whatever regarding this valuable excretion. Now the ultimate object of analysis of urine for urea is to determine the amount of burned up tissue excreted each twenty-four hours. We know that for that time tissue waste should be represented in the ordinary individual by an excretion of from twenty to thirty-five grams of urea, and if the quantity falls below the minimum, with other known pathological conditions, there is reason to believe that this excretion is not being properly eliminated. My attention was called again to this form of statement in an article published in The Journal, Nov. 11, 1905, page 1489, where the pathologist reports (if the quotation is accurate) that an examination of the urine "showed a specific gravity of 1007, indican slight, urea 59 per cent." I do not wish to question the accuracy of the analysis, paradoxical as it appears, but would simply call attention to the fact that this percentage, as in all other like statements, without giving the quantity of urine passed, gives the reader absolutely no information as to the excretion of urea, except that some was excreted. If the pathologist will give the amount of urine each twenty-four hours, and the per cent. of urea found, the reader can figure it out and learn the quantity in grams or grains, when the reader or auditor will have a fact of some specific importance relative to the condition of this excretion.

William H. Dudley, M.D.

Answer.—Your criticism is altogether correct, and we assume part of the blame in not seeing the fault and calling Dr. Cott's attention to the error before publishing the paper. There is altogether too much laxity in reporting urinary findings in general, and urea figures in particular, and in interpreting them.

Urea determinations, to be of value, should be performed in the total 24 hours' quantity for several days in succession; moreover the diet, especially the nitrogenous articles of food and the total liquids, should be included in the calculation, for the urea of the urine is in great part derived directly from the nitrogenous elements of the food (chiefly albumins) and in lesser part from the dissimilation of the body tissues proper. Any deviation from the normal, therefore, either in the amount of nitrogenous pabulum ingested or in the power of the gastroenteric walls to absorb it must needs become manifest in the urine—a copious amount of albumin in the food causing a large urea excretion, a small amount a correspondingly diminished urea excretion; a healthy gastric and intestinal function leading to greater urea excretion after the same amount of nitrogenous food than a diseased one. Other important elements must be included in the calculation:

1. *The amount of exercise;* a resting individual always excretes less urea than a subject indulging in much physical exercise, for the latter destroys more of his own tissues.

2. *The amount of liquid intake*; abundant water drinking at first always causes a broad stream of urea to enter the urine, for all residual circulating urea is in this way flushed out; the same applies to certain (particularly saline) diuretics.

3. *The presence or absence of fever*, a febrile subject always passing more urea than an individual with a normal temperature for in the former the catabolism of the body tissues is more active.

4. *The alkalinity, i. e., acidity of the blood*, any factor that determines acidosis, i. e., a reduction in the blood alkalinity, reduces the urinary urea, for abnormal acids (oxybutyric, diacetic, lactic, phosphoric, uric, etc.) or normal acids in excessive quantity that may enter the bloodstream immediately combine with ammonia and bear the latter with them into the urine; as, now, ammonia is the physiologic precursor of most of the urea that is manufactured in the liver, it is clear that this loss of ammonia means a corresponding decrease in the amount of urea that is formed in the liver, enters the blood-stream and thence the urine.

5. *The state of the liver function.* Any element that produces insufficiency of the hepatic cells also produces a decrease of the urinary urea; this is apparent from what has been said above, for when the liver cells are no longer adequate to form urea from ammonia salts, less urea must of necessity appear in the urine.

It will be seen, therefore, that the urea excretion is by no means an index *per se* of the state of the renal function, but that it is merely an expression of the state of the general metabolism as influenced by the divers factors enumerated above. How crude it is to interpret a small percentage of urea in a single specimen of urine to signify insufficiency of the kidneys! and how commonly is this error committed!

Granted even that all the elements named above were carefully considered, that the determination were performed with the mathematical accuracy of a metabolic experiment, even then a decreased urea excretion might mean nitrogen retention, i. e., be a good omen, especially if the patient gains in weight. At best, if this interpretation could not be accepted, it would mean that the kidneys did not permit the passage of urea but might be permeable for other urinary bodies; for little correspondence exists between the retention of the different urinary ingredients. It might finally mean that less urea than normal is formed while the kidneys were at the same time quite permeable for whatever amount of urea actually reached them in the renal blood and clamored for elimination. When one considers, finally, that, especially in chronic nephritis, the permeability of the kidneys varies from day to day, that in some renal disorders affecting chiefly one kidney, the healthier organ vicariously assumes a compensatory hyperfunction, that finally abnormal amounts of urea might be circulating while the kidneys were partially impermeable, and that as a result an approximately normal amount of urea would appear in the urine; when one considers all these points, and many more that can not be elaborated, it is clear that our correspondent's point is well taken, and that the only objection to his criticism is that it stops far short of the actual deplorable state of modern urea determinations and their clinical interpretation by practicians in general.

State Boards of Registration

COMING EXAMINATIONS.

Missouri State Board of Health, Kansas City, December 19-21. Secretary, J. A. B. Adcock, Warrensburg.

California State Board of Medical Examiners, San Francisco, December 20. Secretary. Charles L. Tisdale, San Francisco.

Utah State Board of Medical Examiners, Salt Lake City, January 1. Secretary, R. W. Fisher, Salt Lake City.

Arizona Board of Medical Examiners, Phoenix, January, 1-2. Secretary, Ancil Martin, Phoenix.

Washington State Medical Examining Board, Spokane, January 2. Secretary, C. W. Sharples, Seattle.

Oregon State Board of Medical Examiners (Regular), Portland, January 2. Secretary, Byron E. Miller, Portland.

North Dakota State Medical Examining Board, Grand Forks, January 2. Secretary, H. M. Wheeler, Grand Forks.

Minnesota State Board of Medical Examiners, Old Capitol Building, St. Paul, January 2-4. Secretary, C. J. Ringnell, Minneapolis.

Rhode Island State Board of Health, State House, Providence, January, 4-5. Secretary, G. T. Swarts, *Providence*.

Arkansas Medical Board, Little Rock, January 9. Secretary, J. P. Runyan, Little Rock.

New Hampshire State Board of Medical Examiners, State House, Concord, January 9-10. Secretary, H. C. Morrison, Concord.

Vermont State Board of Medical Registration, Burlington, January 9-11. Secretary, W. S. Nay, Underhill.

Wisconsin Board of Medical Examiners, Pfister Hotel, Milwaukee, January 9-11. Secretary J. V. Stevens, Jefferson.

South Dakota Board of Medical Examiners, Sioux Falls, January 10-11. Secretary, H. E. McNutt, Aberdeen.

District of Columbia Board of Medical Supervisors, Washington, January 11. Secretary, W. C. Woodward, Washington.

Illinois State Board of Health, Great Northern Hotel, Chicago, January 18-20. Secretary, J. A. Egan, Springfield.

Albany State Board of Medical Examiners, January 30-February 2. Secretary, Charles F. Wheelock, Albany.

Iowa Reports.—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports the examinations held at Des Moines, March 22-23; Keokuk, April 20-21; Sioux City, May 1-3; Des Moines, June 5-6; Iowa City, June 8-9, and at Des Moines, June 22-23.

At the examination held at Des Moines in March the number of subjects examined in was 8; the total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 16, of whom 7 passed and 9 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
Barnes Med. Coll., St. Louis	(1905)	81
College of P. & S., Chicago	(1892)	87
Drake University Des Moines	(1905)	82
National Med. Univ., Chicago	(1904)	80
Northwestern University Woman's Med. School	(1892)	86
Rush Med. Coll., Chicago	(1903) 88; (1905)	88
FAILED.		
Barnes Med. Coll., St. Louis	(1901) 69, (1902)	72
Rush Med. Coll., Chicago	(1900)	63
Marion Sims-Beaumont Med. Coll.	(1904)	71
University of Iowa	(1904)	74
Eclectic Med. Inst., Cincinnati	(1905)	69
College of P. and S., Chicago	(1904)	65
American Med. Coll., St. Louis	(1903)	58
Chicago Homeo. Med. Coll.	(1904)	73

At the written examination held at Keokuk April 20-21, 1905, the number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 54, of whom 48 passed and 6 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
Barnes Med. Coll., St. Louis	(1901)	77
College of P. & S., Keokuk (1905), the grade of 75 was reached by two; 77, by two; 78, by four; 79, by three; 81, by four; 82, by three; 83, by two; 84, by seven; 85, by five, 86, by three; 87, by three; 38 and 89 by two each, and 76 and 80 by one each.		
Rush Med. Coll.	(1902) 87; (1905)	81
College of P. & S., St. Louis	(1905)	80
FAILED.		
College of P. & S., Keokuk..(1902) 70; (1904) 74; (1905) 62, 67, 74, 74..		

At the written examination held at Sioux City, May 1-3, 1905, the number of subjects examined in was 8; the total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 14, all of whom passed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
Sioux City Coll. of Med..(1905) 81, 83, 83, 83, 83, 84, 84, 84, 84, 85, 86, 86, 89.		
Trinity University, Toronto, Canada	(1904)	80

At the written examination held at Des Moines, June 5-6, 1905, the number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 25, of whom 21 passed and 4 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
Barnes Med. Coll. St. Louis	(1902) 78; (1905)	80, 83
College of P. & S., Chicago	(1905)	86
Creighton Med. Coll., Omaha	(1905)	89, 90
Drake University, Des Moines, (1904), 79. (1905) 81, 81, 81, 82, 83, 84, 85, 86, 87, 88.		
University of Michigan	(1904)	88
Western Med. Coll., London, Ont.	(1905)	82, 83
FAILED.		
University Med. Coll., Kansas City	(1897)	0
Rush Med. Coll., Chicago	(1899)	70
Illinois Med. Coll., Chicago	(1905)	74
Eclectic Med. Inst., Cincinnati	(1903)	69

At the written examination held at Iowa City, June 8-9, 1905, the number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 69, all of whom passed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
College of P. & S., Chicago	(1905)	85
University of Iowa (1905). The grade of 78 was reached by four; 79, by two; 80, by two; 81, by five; 82, by two; 83, by five; 84, by five; 85, by ten; 86, by six; 87, by four; 88, by eight; 89, by eight; 90, by three; 92, by two, and 91 and 95 by one each.		

At the written examination held at Des Moines, June 22-23, 1905, the number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 19, of whom 17 passed and 2 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
College of P. & S., Chicago	(1905) 76, 76, 80.	81
Hahnemann Med. Coll., Chicago	(1905)	89
Jefferson Med. Coll., Philadelphia	(1904)	83
Northwestern University	(1905) 83, 85, 86, 87, 88,	90
Queen's University Kingston, Ont.	(1905)	76
University Med. Coll., Kansas City	(1905)	81
University of Michigan	(1905)	84
University of Minnesota	(1899)	83
University of Pennsylvania	(1902)	79
FAILED.		
University Med. Coll., Kansas City	(1897)	57
Ensworth Med. Coll., St. Joseph	(1905)	64

Iowa September and October Reports.—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports the written examinations held at Des Moines, Sept. 13-14, and Oct. 18-19, 1905. At both examinations the number of subjects examined in was 8; total number of questions asked, 100; percentage required to pass, 75.

At the September examination the total number of candidates examined was 23, of whom 19 passed and 4 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
College of P. and S., New York	(1905)	86
Homeo. College of Missouri	(1904)	79
Howard University, Washington, D. C.	(1905)	80
Jefferson Med. Coll.	(1905)	81, 89
Marion-Sims-Beaumont Med. Coll.	(1898) 77; (1903)	83
National Med. Univ., Chicago	(1904)	83
Northwestern University	(1905)	87, 88
Queen's University, Kingston, Ont.	(1904)	78
Rush Med. Coll.	(1905) 82, 87,	90
Toronto Med. Coll.	(1905)	76
University of New York City	(1897)	79
University of Pennsylvania	(1905)	87
Western Reserve University	(1893)	83
College of P. & S., Milwaukee	(1900)	77
FAILED.		
College of P. & S., St. Louis	(1904)	66
Ensworth Med. Coll., St. Joseph, Mo.	(1905)	72
Eclectic Med. Inst., Cincinnati	(1903)	71
College of P. and S., Chicago	(1905)	71

At the October examination the total number of candidates examined was 7, of whom 5 passed and 2 failed. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
Rush Med. Coll.	(1904)	87
Johns Hopkins University	(1905)	78
Keokuk Med. Coll.	(1903)	84
University of Kentucky, Louisville	(1904)	88
Woman's Med. Coll., Philadelphia	(1904)	85
FAILED.		
College of P. and S., St. Louis	(1904)	56
College of P. and S., Chicago	(1905)	71

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending December 9:

Cowper, H. W., asst.-surg., relieved from duty in Philippines Division, and ordered to Washington Barracks, D. C., for temporary duty, at expiration of sick leave.

Snyder, Henry D., surgeon, left Fort Sam Houston, Tex., for duty at State Militia Camp, Austin, Texas.

Lewis, Wm. F., asst.-surgeon, on his arrival at San Francisco, will proceed to Chicago, for duty as attending surgeon and examiner of recruits.

Manly, C. J., asst.-surgeon, granted 30 days' leave of absence.

Wall, Francis M., contract surgeon, returned to Fort Oglethorpe, Ga., from target range.

Dickenson, Clarence F., contract surgeon, left Fort Logan, Colo., on leave of absence.

Slater, Ernest F., contract surgeon, left Washington Barracks, D. C., on sick leave of absence for ten days.

Leeper, John F., contract surgeon, granted leave of absence for two months in the United States, from the Philippines Division.

Pinquard, Jos., contract surgeon, ordered from the Philippines Division to the United States for annulment of contract.

Enders, Wm. J., contract surgeon, granted leave of absence for one month, ten days.

Brooks, John D., contract surgeon, granted leave of absence for 30 days.

Parkman, Wallace E., contract surgeon, arrived at Presidio of San Francisco for temporary duty.

Mount, Jas. R., contract surgeon, granted leave of absence for three months in the united States from the Philippines Division.

Newlove, George, contract surgeon, ordered to San Francisco, as witness before a general court martial, after which he will resume his leave of absence from the Philippines Division.

Wertenbaker, C. I., contract surgeon, granted leave of absence for one month.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending December 9:

Huntington, E. O., surgeon, ordered to treatment at the Naval Hospital, New York, N. Y.

Woodward, J. S., asst.-surgeon, detached from the *Brooklyn* and ordered to Colon, Panama, for special duty.

Holloway, J. H., asst.-surgeon, ordered to the Navy Yard, Norfolk, Va.

Wise, A. H., acting asst.-surgeon, detached from duty with the Naval Recruiting Party No. 1, December 16, and ordered to the Navy Yard, Washington, D. C.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending December 6:

Vaughan, George T., asst. surgeon general, granted leave of absence for two months and eight days from December 1.

Gassaway, J. M., surgeon, reassigned to duty at St. Louis, Mo., effective Aug. 2, 1905.

Meade, F. W., surgeon, on being relieved by Surgeon A. C. Smith, to proceed to Charleston, S. C., for duty.

Kalloch, P. C., surgeon, authorized to attend meeting Maine State Board of Health, at Augusta, Dec. 7, 1905, relative to smallpox.

White, J. H., surgeon, relieved from duty at Mobile, Ala., and from special temporary duty in New Orleans, La., and directed to assume charge of the service at New Orleans, La., relieving Surgeon A. C. Smith.

Smith, A. C., surgeon, relieved from duty, New Orleans, La., and directed to proceed to Pittsburg, Pa., for duty, relieving Surgeon F. W. Meade.

Corput, G. M., P. A. surgeon, relieved from duty at Pascagoula, Miss., and directed to report to Surgeon, J. H. White, New Orleans, La., for special temporary duty.

Wilson, R. L., P. A. Surgeon, relieved from duty at Vera Cruz, Mexico, and directed to report to the medical officer in command, New Orleans, La., for duty and assignment to quarters.

Wilson, R. L., P. A. surgeon, granted fifteen days' leave of absence en route from Vera Cruz, Mexico, to New Orleans, La.

Berry, T. D., P. A. surgeon, relieved from duty at Biloxi, Miss., and directed to proceed to New Orleans, La., reporting to Surgeon J. H. White for special temporary duty.

Earle, B. H., P. A. surgeon, reassigned to duty at Columbia River Quarantine Station, Astoria, Ore.

McKeon, F. K., asst.-surgeon, granted leave of absence for ten days from December 22.

Duke, B. F., acting asst.-surgeon, granted leave of absence for twenty-five days from November 29.

Rodman, J. C., acting asst.-surgeon, granted leave of absence for five days from December 3.

Stearns, W. L., pharmacist, granted leave of absence for twenty-one days from December 9.

Maguire, E. S., pharmacist, granted leave of absence for thirty days from December 2.

Van Ness, George I., Jr., pharmacist, granted eleven days' leave of absence from December 4.

RESIGNATION.

Vaughan, George T., asst. surgeon-general, resigned, to take effect Feb. 9, 1906.

Medical Organization

North Carolina.

State Medical Society.—We have received a reprint of the presidential address by Dr. D. T. Tayloe before the last meeting of the Medical Society of the State of North Carolina. The principal topic discussed in the address is the value of hospitals, and President Tayloe's plea for more hospitals of the right kind will be indorsed by the profession generally. We are particularly interested, however, to note the progress of the work of organization in North Carolina, as indicated in the address, from which we quote:

"I can not refrain from congratulating the society on the success the new plan of reorganization has achieved, sufficient beyond all doubt to satisfy the most skeptical. In 1903 the state society had nearly 500 names on the roll, but only 283 were in good standing (on account of dues). In June, 1903, we reorganized, and at that time had less than ten county organizations in the state. In May, 1904, we met and had double the attendance we ever had at any state society meeting, and there have been sent out transactions for 1904 to 1,065 members whose dues are paid up for that year. This speaks for itself. I wish to add, however, that this fine showing is to a large extent due to the efforts of our efficient secretary, Dr. J. Howell Way, who has spent much time and energy in furthering the progress of this great work, there being few men who could have accomplished such results.

"I wish to impress on the different county organizations the importance of having an efficient, painstaking and business-like secretary, as much of the work devolves on him, and much of the success of the society is through his efforts.

"The society is also to be congratulated on having such efficient members in the Senate and House of Representatives as successfully to defeat the progress and invasion in our state of quacks, osteopaths and other designing fakes. To this same body is due also our thanks and the sincere thanks of the entire state in establishing a state laboratory of hygiene, which was much needed and which is a public beneficence."

Society Proceedings

COMING MEETINGS.

American Dermatological Association, New York, Dec. 28-30.

Western Surgical and Gynecological Association, Kansas City, Mo., Dec. 27-28.

State Board of Health of Missouri, Kansas City, December 19-21. Secretary, J. A. B. Adcock, Warrensburg.

Board of Medical Examiners State of California, San Francisco, December 20. Secretary, Charles L. Tisdale, San Francisco.

THE AMERICAN SOCIETY OF TROPICAL MEDICINE.

Meeting held Nov. 17, 1905.

Dr. Roland G. Curtin in the Chair.

Study of Tropical Medicine.

Dr. F. C. Wellman of Benguella, Angola, West Indies, contributed this paper, which was read by Dr. Joseph McFarland, president of the society. The author referred to the comparatively recent growth of the remarkable and general interest in the problems of tropical pathology. When Sir Patrick Manson published his study of *Filaria sanguinis hominis* in 1883 but little scientific knowledge of tropical ailments had been collected. Dr. Wellman thought no one could claim to be *au courant* with the science of general medicine without an appreciative acquaintance with the leading facts of tropical pathology. The following statements were made by the author: 1. The successful settlement of the tropics is of very great importance to the world. 2. Such settlement depends in no small measure on the solution of various hygienic and epidemiologic problems there obtaining. 3. In the absence of this knowledge an enormous extra expenditure of lives and money is certain to ensue. 4. The problems in question can best be studied and met by trained observers, scientific medical men living in the tropics. Methods of study were discussed by reference to some of the best work done in the past, for instance, that on the subject of animal parasites by Cobbold, Leuckart, Blanchard, Stiles and Braun, Laveran, Manson, Ross and others. With reference to the personal equation, Wellman quoted Sir Patrick Manson in that "the student of medicine must be a naturalist before he can hope to become a scientific epidemiologist or pathologist, or a capable practitioner." Reference was made to the very incomplete state of knowledge of the geographical distribution of disease. The epiphytic skin diseases of the tropics, the behavior of the ordinary bacteria in hot climates, and the peculiar form which some cosmopolitan diseases assumed in warm countries offered fruitful fields for investigation. Another subject of great moment is that of the intermediate hosts which subserved various parasites. For example, the life history and seasonal prevalence of comparatively few mosquitoes and other blood-sucking diptera had been observed. Of 13 species of mosquitoes collected by himself in a small district in West Africa 7 were new to science. Of 11 different biting-mouthed flies only one had been previously described, and the district was shown to rejoice in several new blood-sucking ticks. In conclusion suggestions were made of special work worthy of attention in the following connection: The completion of the investigation of the so-called Leishman-Donovan bodies; explanation of the puzzling dyscrasia in certain obscure fevers; observation of the new Maxwell-MacLean disease; critical examination of the suggested relation between ainhum and leprosy; further confirmation of the work done by Ross and Milne and the Liverpool School on "tick fever," and by Christy and Feldman on the intermediate host of *Filaria perstans*—a study of the neglected *Sarcorporidia* and gregarines of the tropics, to say nothing of the special hygienic, surgical and ophthalmologic questions which specialists in hot climates have raised. All these, he thought, indicate that the scope of tropical medicine is practically unlimited and that the work is still in its commencement.

Uncinariasis.

DR. CLAUDE A. SMITH, Atlanta, Ga., gave the results of his observations and experiments in connection with the disease, and especially of his investigation of infection through the skin. His patients had given a history of "ground itch," although many who did not have the disease also gave a history of "ground itch." Investigation showed that those patients who had had "ground itch" and did not have the parasites in the intestines, had the eruption a great many years before. It was, therefore, supposed that the parasites had died out in the intestines in the meantime. A study of the life history of the parasite showed that in an attack of true ground itch within a period of about eight years, the parasite was always present in the intestines. Ground itch is very common throughout the South, where it is also known as "dew poison," "toe itch." These terms, however, might be misleading, as their significance differs in different localities. True ground itch, he said, appears almost invariably after the person has been walking barefoot in the mud, especially if the ground had been wet for several days. The itching at times becomes excruciating. Macules at the points of irritation rapidly change to vesicles, which remain discreet or confluent and usually rupture. The duration of the attack varies from two to several weeks, dependent on treatment and the spread of the infection by scratching.

Dr. Smith's investigations of the source of infection show that the water could not be the cause in most of the cases, nor lack of cleanliness. Further investigation shows that the disease is of the country and not of the city. In a study of the parasite itself he found that to hatch the eggs of uncinaria the best plan is to use a Petri dish with a snugly fitting top. The process of hatching and the development and habits of the larvæ were minutely described. Little motility is displayed by the organisms while in the Petri dish, but if placed on a slide they move rapidly for a few minutes to half an hour, when they lie perfectly still for a corresponding length of time with their bodies perfectly straight, after which they again resume their lively motions. The life of the larvæ may be maintained in the Petri dish for three to four months. The diagnosis of the disease can only be made by the finding of the eggs of the parasite in the stools. The treatment is simple and effective, and consisted in the administration of thymol and purgation. Thymol, however, should never be given without a preliminary examination of the stools with the microscope. A purgative is given at night, usually of salts, followed in the morning by 30 grains of thymol. Two more doses are given at intervals of two hours, followed by another large purgative. A second treatment in the course of a week practically clears up the intestines. If indicated, the treatment is to be repeated. The indifference of the patient to infection is a marked feature. In the treatment of a case there should be close observation on the part of the physician because of the possible bad results of thymol.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Nov. 29, 1905.

The President, DR. CHARLES S. BACON, in the Chair.

Etiology, Diagnosis and Treatment of Perinephritic Abscess.

DR. RAMON GUITERAS, New York City, reported 15 cases, and emphasized the following conclusions: 1. Many more cases of perinephritic abscesses are due to suppurative renal disease than is generally supposed. 2. Traumatism, exposure and similar influences to which perinephritic abscess is attributed are not so important as many observers have claimed; they are given as causes when they are simply coincidences, or the active cause of rupture of already existing abscesses of the kidney or neighboring structures. 3. It is important, though difficult, to determine the source and course of the pus; therefore, during the operation the surgeon should try to determine whether the kidney is the source, and, if not, what tissue is the source. It is quite important to discover the route taken by the pus, as it indicates where counter-incisions should be made, and the further treatment of the complications of the case. 4. The elements of success in operations for perinephritic abscess may be summed up as follows: (a) Early operation, incision and evacuation before the pus has had time to burrow extensively; (b) thorough exploration without timidity, opening the kidney and exploring the ureter if need be; (c) thorough drainage down the deepest part of the sac by means of large rubber drains of gauze, the drain being kept in place until a well-formed sinus exists down the deepest part of the cavity; (d) secondary nephrostomy or nephrectomy, if indicated at the time of the operation, later. 5. Nephrectomies are exceedingly dangerous in these cases, and it is better to perform nephrotomy or to content one's self with the simple opening of the abscess cavity even though a sinus results.

Sanatorium Treatment of Tuberculosis.

DR. G. W. HOLDEN, Denver, said that the first aim of any institution should be to restore to a life of usefulness those who are afflicted with this disease. A most important object is the education of those reached directly and indirectly by the work of such an institution. Holden reported on the cases treated at the Agnes Memorial Sanatorium during one year. Two hundred and twenty-four patients were admitted, 107 discharged, 8 dismissed for non-observance of rules, and 13 remained less than one month. Of 102 cases, whose average stay was from six to eight months, 13 were discharged apparently cured, 28 arrested, 43 improved, 16 unimproved, with progressive disease, and 2 died. The cases fell into three classes—the incipient or favorable cases, the moderately advanced, and the far advanced. Of the incipient cases 64.70 per cent. were discharged apparently cured, 17.65 per cent. were arrested, 17.65 per cent. were improved. In none did the disease progress, and none died. Of the cases moderately advanced 4.65 per cent. were discharged apparently cured, 39.54 per cent. were arrested, 46.50 per cent. were improved; in 9.30 per cent. the disease was progressive; none died. Of the far advanced cases none was cured, 19.05 per cent. were arrested, 47.62 per cent. were improved; in 38.57 per cent. the disease was progressive, and 4.76 per cent. died. Holden says forced feeding is not essential nor desirable to obtain results. He prefers to depend on an abundance of good food served in the three regular meals, in conjunction with the careful regulation of the life of the patient. Constant attention is paid to assimilation and elimination. Of the incipient cases 17 gained 132 pounds, an average of 7¾ pounds. This is a small gain for each case, but the majority of incipient cases are not emaciated. Of the cases moderately advanced 38 gained 432 pounds, an average gain of 11 1/3 pounds. In exceptional cases exceptional gains were made. Of these cases 5 lost 16¾ pounds, an average of 3 1/3 pounds. His experience shows that when a patient is near his average weight, the gain or loss is not always an index of the pulmonary condition, and after all, the lung condition is the vital matter. Of the far advanced cases 29 gained 288 pounds, an average of 10 pounds; notwithstanding this gain their pulmonary findings placed them in this class; 13 lost 53¾ pounds, an average of 4 pounds plus. Dr. Holden gave an excellent idea of what they are doing at the Agnes Memorial Sanatorium, a work which has been made possible through the philanthropy and public spirit of Mr. Lawrence C. Phipps.

Behring's New Tuberculosis Remedy.

DR. ARNOLD C. KLEBS read this paper, which appears in this issue of THE JOURNAL.

Economic Aspect of Modern Treatment of Tuberculosis.

DR. J. W. PETTIT, Ottawa, Ill., said that it is primarily based on life in the open air. To meet this demand we must make a radical departure from the conventional plan of hospital construction. It is perfectly natural that sanatoria should at first copy the usual methods of hospital construction, hence there has arisen altogether too expensive an ideal. The great difficulties encountered in carrying out the open-air treatment are so formidable that any method which will cheapen or simplify the treatment should be carefully considered. Providing tuberculous patients with sleeping apartments in substantial buildings is not only unnecessary, but in violation of an essential principle which has for its object supplying the patient with fresh air. The simplest and least expensive method which would protect the patient from the inclemency of the weather and supply him with the largest amount of the best possible air is the one which commends itself for scientific and economic reasons. We should proceed on the principle of the greatest good to the greatest number. If we can make a given sum of money which is now expended in the care of one patient provide for several, it is our duty to do so. This can be done. This is the problem they have been trying to work out at the Ottawa tent colony, and, they believe, with some degree of success. Since the tent is practicable in a cold climate, it should be used more extensively. It fulfills the conditions most perfectly from a scientific standpoint. The difficulty of keeping patients in the open air is well known. Every temptation placed before them in the way of indoor comforts only adds to the difficulty. The only way to insure patients getting fresh air is to place them where they can get nothing else. To be consistent, patients should be kept out of doors not part of the time, but all the time. In no other way can this be done so easily and satisfactorily as in a tent. A tent is an ideal method of housing tuberculous patients in a mild climate. The cost of food is the most expensive item in the treatment of tuberculosis, and any attempt to cheapen this feature by cutting down the quantity or cheapening the quality will tend to nullify the treatment just to the extent to which this is done. The psychical element must also be considered. This makes it necessary to provide certain forms of amusement and recreation which adds somewhat to the expense.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Nov. 8, 1905.

The President, DR. JAMES M. ANDERS, in the Chair.

Morbid Physiology of Neurasthenia.

DR. WILLIAM PICKETT pointed out that the Greek root "sthen" meant strength in the sense of dynamic strength, and that asthenia was, therefore, want of endurance rather than simple weakness. In myasthenia gravis the muscles supplied by the bulb are quickly exhausted by use—asthenic bulbar paralysis Strümpell called it, from its parallelism to organic bulbar palsy. Another condition of muscular exhaustibility—asthenopia—resembles a certain organic disease—oculomotor palsy. A general exhaustibility, affecting various organs and functions, suggests by further analogy a disease of the general nervous system, which is called neurasthenia. Added to ready exhaustibility in neurasthenia is a want of recuperative power; so that in the confirmed case the patient not only tires readily, but is always tired. The symptoms of irritability in neurasthenia are apparently due to diminished control of higher centers which are fatigued, a mechanical instance of which is the increased knee jerk, explained, as in organic nervous disease, by overaction of spinal centers, partly released from the control of the motor cortex. By this reasoning, Dr. Pickett said, neurasthenia might appear as a functional brain disease. In neuropathic persons the exhaustion affects the highest centers, causing certain psychic symptoms. These, especially the obsessions (*folie du doute*, morbid fears, impulsions and imperative ideas), constitute the psychiasthenia of Janet. Neurasthenia is a simple fatigue neurosis, not to be confounded with the symptomatic states of exhaustion in phthisis, heart disease, the febrile affections, early paresis, etc. These are to neurasthenia what the "typhoid state" is to typhoid. The chemistry of fatigue does not explain neurasthenia, nor is it likely that there is actual degeneration of cortical cell bodies, as alleged by some writers.

Diagnosis of Neurasthenia.

DR. F. X. DERCUM said that in the study of a case of nervousness there should be considered: First, the three great neuroses—neurasthenia, hysteria and hypochondria; second, the various nervous states prodromal to the fully developed psychoses, such as the prodromal or developmental period of melancholia, or paranoia, of dementia præcox and the like. These states, which never present the symptom group of neurasthenia, he terms the neurasthenoid states. The symptoms they present are never truly neurasthenic, but are like or grossly resemble neurasthenia. Finally, there should be borne in mind the nervous symptoms which accompany various visceral and general diseases, organic and functional. Here again, he said, the nervous symptoms are never those of true neurasthenia; there is present merely a neurasthenia symptomatica, as in chlorosis and other blood diseases, and in diseases of the viscera. In the study of neurasthenia, in detail, the symptoms are found to be essentially those of chronic fatigue, of a fatigue which has become exaggerated and pathologic, and for this reason Dr. Dercum applies to neurasthenia the term "*fatigue neurosis*." Analysis of the symptoms of neurasthenia shows an expression of the sensory symptoms in generalized fatigue sensations, such as a general sense of tire and of weakness; second, in localized fatigue sensations, such as headache, backache and limbache. Of the motor symptoms there are found in varying degree muscular fatigue, muscular weakness and, above all, ready muscular exhaustion. In the psychic symptoms there is diminution in the capacity for sustained mental effort, ready mental exhaustion and diminution in the spontaneity of thought. In the somatic symptoms are noted especially atony of the digestive tract, atony of the circulatory apparatus and disturbances of the secretions, indicating weakness of defective innervation, and disturbance of the sexual functions, indicating weakness and irritability. These Dr. Dercum termed the essential symptoms of neurasthenia; the other symptoms that make their appearance are the secondary or adventitious symptoms.

Treatment of Neurasthenia.

DR. CHARLES K. MILLS regards neurasthenia as a true clinical entity. Genuine neurasthenia, relatively rare, occurs outside of the psychiatric pale. The main features in the treatment of neurasthenia are rest, the skillful use of diet, exercise, work, medicines and special measures, such as massage, electricity and hydrotherapy. No matter what treatment is instituted, suggestion properly used plays an important part. The sufferers from neurasthenia are often, if not always, neurotic or neuropathic, and for this reason the psychic treatment is important. With the co-operation of the family something can be done to secure relative rest for the neurasthenic. There should be nine or ten hours' sleep and one-day period of rest should be insisted on. This should not be less than fifteen minutes and need not be more than two hours. Massage he considered of more value than electricity, although both can be made to play important parts as adjuvants in the partial as well as in the complete rest treatment. A well-chosen mixed diet should be aimed at, although it is often necessary to begin with milk alone, to continue for some time with milk and eggs, the latter, preferably, to be given raw. Digestion and assimilation of food should be secured. Systematized respiratory exercises indoors, or golf playing, horseback riding, etc., can be resorted to, if feasible. In carrying out a complete rest treatment the first point to be insisted on is absolute isolation. Much depends on the judgment, tact and intelligence of the nurse. Mistakes are sometimes made by putting cases of mental disorder, supposed to be instances of neurasthenia, under the rest treatment. In a few cases even genuine neurasthenia does not do well under this treatment. In the rest treatment everything should be scheduled with the greatest care and accuracy. Seasonable vacations, as methods of bringing about rest, should be at least two in number; one comparatively long at the usual summer period and the other late in February or early in March. Neurasthenic attacks might sometimes be prevented, if the patient would take a period of short but complete rest, away from his usual environment, in March. Work is sometimes beneficial in the treatment of neurasthenia. Care should be taken, however, in its selection and manner of performance. In the treatment of insomnia, sulphonal and chloralamid are the most useful hypnotics, although it is often possible to produce sleep by massage and mild hydrotherapeutic measures. Little medicine is needed. The most valuable drugs are those which aid digestion, improve circulatory tone, and strengthen nerve centers. Chlorid of gold and sodium, arsenic, salts of zinc, strychnin or nux vomica in small doses, cactus, asafetida and caffein are useful agents.

DISCUSSION.

MAJOR CHARLES A. WOODRUFF, U. S. A., spoke of neurasthenia in the tropics, with especial reference to its existence in the Philippine Islands, where the condition has been recognized sufficiently to be termed tropical neurasthenia. European physicians do not take the same view of neurasthenia as do American physicians, and consequently they are apt to call the prevailing nervous conditions by different names. The most important symptom observed in neurasthenia in the Philippines is loss of memory, which condition, in young men, disappears on their return home. Severe indigestion, accompanied by dysentery, is another form. Even a soft boiled egg, at times, causes intense suffering. In the tropics the indigestion of neurasthenia means starving to death. It is not unusual to see men carried from the hospital to the ships, apparently to die, but by the time they reach Japan there is much improvement, and on their arrival at San Francisco there has been a gain in weight of from twenty to thirty-five pounds. Major Woodruff found that among the soldiers of blonde complexion the morbidity rate is much larger than among the brunettes, almost double. This same condition exists in families; one daughter, a blonde, being decidedly neurasthenic; the other, a brunette, being comfortable and enjoying the climate. Further investigations showed that in Scandinavia, Scotland and the southern and central part of Norway there are more blondes than anywhere else in the world, and that going toward the southern end of Italy there are but few. White men who go to India do not survive the third generation. If the white man goes too far out of his dark corner death stares him in the face. The matter is regarded as interesting in its relation to tuberculous patients, and an instance was cited of a patient cured at Saranac who went to Denver, but found himself becoming exceedingly nervous. This man was a decided blonde. A comparison of the death rates of various parts of the United States shows the lowest to be in the northwest corner—Washington, Oregon and Alaska— where there is a minimum of sunshine, proving the existence of good health conditions in spite of the lack of sunshine. The practical point made was that in seeking a change of climate blondes should not be sent south.

DR. WHARTON SINKLER thinks it as common to find cases of unrecognized neurasthenia as to find cases of organic disease diagnosed neurasthenia. He regards neurasthenia as a fatigue neurosis. The condition is more common and more obstinate in men than in women. The treatment depends not so much on the means of the patients as on the temperament. Some do well under the ordinary rest treatment; others by being driven to exert themselves when they feel a disinclination to action.

DR. JOHN K. MITCHELL said that he has seen a case of dilated stomach, one of locomotor ataxia in the early stages, but distinct, and two cases of Bright's disease, which had been diagnosed neurasthenia. A very important—and, perhaps, a neglected—part of the treatment is punctuality and accuracy. Mild neurasthenic cases may be treated successfully by the mere regulation of their lives. The cardinal symptom of indecision is helped, because there is nothing to decide; certain things are to be done at stated hours. This treatment might be made to include a man's business or a woman's household duties. In fact, the whole object of the treatment of neurasthenia, the conservation of energy, can only be secured by rest and punctuality.

DR. CHARLES W. BURR cited a hospital case which had been diagnosed as one of neurasthenia. The patient died suddenly and the autopsy showed the case to be one of fatty heart. True neurasthenia is not a common disease. Too often hypochondriasis is included as a part of neurasthenia. Rest treatment for such patients is not successful, and this is responsible for the belief held by many that the rest cure possesses little merit.

DR. WILLIAM G. SPILLER emphasized the fact of the frequency of association of hysteria and neurasthenia, not, however, in the sense of being different manifestations of the same neurosis, nor that the association is the same as that of mania with melancholia; but, he believed that later on there will be found a closer association than is now thought to exist.

DR. A. C. BUCKLEY said that in a number of cases of post-traumatic neurasthenia, there occurred, after the shock passed off, a temporary period of almost normal health before the appearance of the true neurasthenic symptoms. This, he thought, was contrary to the natural expectation, that the symptoms would follow more or less closely on the apparent injury.

DR. FRANK WOODBURY referred to a class of cases suffering from the injurious effects of water gas which are apt to be diagnosed neurasthenia. He cited some instances and thought that in the consideration of neurasthenia such cases might be included under a group of toxic neurasthenias. In treatment the first step is to adjust the patient to his environment.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Ointments in Nasal Affections.

In considering the therapeutic value of ointments in the treatment of diseases of the nose, L. S. Somers, in *Merck's Archives*, states that clinical experience has demonstrated that better results are obtained from this form of medication than from any other. Ointments protect the membranes and upper lip from irritating discharges and, therefore, are soothing. The application of ointments does away with the danger of douches or washes which are so frequently used by patients troubled with catarrhal conditions of the nasal passages, with the accompanying danger of infection of the middle ear by way of the Eustachian tube. Unlike the use of ointments in diseases of the skin, the consistency is of great importance for nasal application. Wool fat (lanum or lanolin) may be used as a base after being rendered sterile.

When these applications are made by the physician the ointment should be applied on a cotton tuft wound tightly on an applicator. The author recommends placing the ointments in a collapsible tube for the patient's use at home. With the head thrown backward, he can insert the tube into one nostril and then into the other. The nostrils should be thoroughly cleansed previously to introducing the ointment. Of the various diseases of the nasal passages in which ointments may be employed either as curative factors or in allaying symptoms, acute rhinitis, according to the author, is probably the most frequent, and this is often relieved in both its early and later stages. During the early part of the disease, when acute coryza is present, the active principle of suprarenal gland is of great service, applied in the following combination:

℞.	Adrenalin	gr. 1/2		03
	Olei geranii	m. i		06
	Lanolini	℥i	30	

M. Sig.: Apply locally to the nares.

The author states that while the strength of adrenalin in the foregoing formula is about the same as the 1 to 1,000 normal saline solution, its action is greatly prolonged and the results are much more satisfactory. It should be used by the patient from two to four times daily, depending on the severity of the coryza. This combination is also of service in such vasomotor conditions as are accompanied by excessive secretion, and in acute exacerbations of chronic rhinitis which is unaccompanied by organic changes.

During the later stages, when the secretion consists of tenacious mucus or becomes mucopurulent in character, one of the following combinations is recommended:

℞.	Olei eucalypti	m. xl	2	65
	Acidi borici	ʒii	8	
	Liq. petrolati			
	vel:			
	Lanolini q. s. ad	℥i	30	

M. Ft. unguentum. Sig.: Apply a small portion in the nostrils several times a day and inhale forcibly.

This will tend to render the secretions less tenacious and at the same time it will aid in restoring their normal character.

The following may be used under similar circumstances:

℞.	Mercuric sulphatis flavi	gr. ii		12
	Lanolini	℥i	30	

M. Sig.: Apply a small portion to the nostrils several times a day.

When the secretion is profuse the following is recommended:

℞.	Acidi gallici	ʒi	4	
	Unguenti belladonnæ	ʒii	8	
	Lanolini	ʒvi	24	
	Liq. petrolati q. s. ad	℥i	30	

M. Sig.: Apply a small amount locally to the nares several times a day.

In vasomotor conditions of the turbinal tissues various remedies prescribed in the form of ointments are especially beneficial in checking excessive secretion and in relieving the obstructions to the nasal respiration. When the tissues are edematous relief may often be obtained by the application of the following ointment two or three times daily:

℞.	Quininæ sulphatis	gr. iiss-viii		15-.50
	Lanolini	℥ss	15	

M. Ft. unguentum. Sig.: Apply locally two or three times a day. Or:

℞.	Ichthyoli	ʒss-ʒi	2-4	
	Lanolini	℥ss	15	

M. Ft. unguentum. Sig. To be applied locally two or three times a week by the physician.

The foregoing is to be used when the irritability to the mucous membrane is not great.

In hyperesthetic rhinitis, not of the true hay fever type, but accompanied by attacks of sneezing and irritability of the nares, a combination similar to the following is recommended as a protective to the mucous membranes and for its soothing qualities:

℞.	Ung. hamamelidis	℥ss	15	

Sig.: Apply locally to the nasal mucous membrane. Or:

℞.	Ung. zinci oxidi	ʒiii	12	
	Lanolini	ʒv	20	

M. Ft. unguentum. Sig.: Apply locally two or three times daily.

In some cases belladonna may seem preferable to the foregoing, combined as follows:

℞.	Ung. belladonnæ			
	Lanolini, āā	ʒii	8	

M. Ft. unguentum. Sig.: Apply locally once or twice daily.

In cases in which the hyperesthesia is of comparatively short duration and it is not desired to continue the treatment for any great length of time the following combination is recommended by the author as one which will cause the symptoms to subside rapidly and the reflex sneezing to stop:

℞.	Cocainæ hydrochlor	gr. v		20
	Olei eucalyptus	m. x		65
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: To be applied locally by the physician as the individual case requires. [Cocain, however, should be used cautiously.—Ed.]

The habit of cocain must be avoided in the use of the foregoing combination as well as in the following combination, which may be used in cases of true autumnal catarrh or hay fever.

℞.	Cocainæ hydrochloratis	gr. x		65
	Menthol (crystals)	gr. xx	1	30
	Olei amygdalæ exp	ʒii	8	
	Ung. zinci oxidi q. s. ad	℥i	30	

M. Ft. unguentum. Sig.: Apply locally by means of a cotton applicator to the nasal mucous membranes, two or three times a day, depending on the severity of the attack.

In cases in which the obstruction is the most prominent symptom of hay fever the following is recommended:

℞.	Menthol (crystals)	gr. iiss-viii		15-.50
	Lanolini	℥ss	15	

M. Ft. unguentum. Sig.: To be applied locally, as often as necessary, by the patient.

As stated by the author, however, when there is a marked increase in the amount of fibrous tissue, the employment of ointments is of no value, as would be the case with any medicinal application which produces no destruction of tissue.

In some cases in which there is slight thickening or induration of tissue the following combinations are recommended:

℞.	Ichthyoli	ʒi	4	
	Olei bergamot	m. v		30
	Ung. zinci oxidi	ʒvii	28	

M. Ft. unguentum. Sig.: Apply locally. Or:

℞.	Bismuthi subgal	gr. xx-xl	1	30-2.60
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: Apply locally.

The foregoing should be applied to the nares two or three times a week by the physician, and the patient should be instructed to use either the adrenalin or menthol ointments several times a day during the intervals.

In rhinitis sicca the following is recommended:

℞.	Olei eucalyp	ʒss-i	2-4	
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: Apply locally at bedtime.

In those cases further advanced and regarded as true atrophic rhinitis, accompanied by excessive dryness, crust formation and offensive odor, the membranes must be thoroughly cleansed and the crusts removed. After this the following ointments are of value:

℞.	Hydrargyri oxidi flavi	gr. v-x		30-65
	Olei bergamot	m. v		30
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: To be applied locally by the patient. Or:

℞.	Ichthyoli	ʒss-i	2-4	
	Menthol (crystals)	gr. v-viii		30-.50
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: A small amount to be inserted into the nostrils at bedtime.

The following are of value applied by means of tampons:

℞.	Iodoformi	gr. xx-xxx	1.30-2	
	Olei eucalyptus	m. v		30
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: Apply to the nares on tampons.

The foregoing is especially valuable when the fetor is marked.

Ointments are the most essential means of treatment in any case in which erosions of the mucous membrane or perforations of the septum are present, whether specific or otherwise. They not only prevent crust formation, but stimulate the parts to healing. For this purpose mercury is recommended as follows:

℞.	Ung. hydrarg. nitratis	ʒi	4	
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: Apply locally in specific cases. Or:

℞.	Ung. hydrarg. nitratis	gr. xx	1	30
	Ung. hydrarg. oxidi rubri	ʒss	2	
	Lanolini	℥i	30	

M. Ft. unguentum. Sig.: Apply locally to the edges of the perforation.

Medicolegal

Makes Recording of Certificate More Important.

Chapter 136 of the Laws of South Dakota of 1905 amends Section 23 of the medical practice act of that state by incorporating the words here inclosed in quotation marks, making the second paragraph of the section read: Any person who shall practice medicine or surgery or obstetrics in any of their branches in this state without having obtained a license as in this act provided, "and had such license recorded in the office of the register of deeds of the county in which such person resides and practices, as hereinabove provided," shall be guilty of a misdemeanor, etc.

To Secure Pure Foods.

Chapter 114 of the Laws of South Dakota of 1905 is entitled: "An act to provide for a state food and dairy department; to prevent the adulteration, misbranding and imitation of foods, beverages, candies and condiments, and regulating the manufacture and sale of dairy products." One of its many provisions is that it shall be unlawful for any person to manufacture, sell, offer or expose for sale any article of food to which has been added formaldehyd, borax, boracic acid, benzoic acid, sulphites or sulphurous acid, salicylic acid, abrastol, beta-naphthol, fluorin compounds, saccharine or coal tar dyes. In Chapter 135 is an act relating to inspection of meats, slaughter houses and markets.

Females to Accompany Female Insane Patients.

Chapter 74 of the Laws of New Jersey of 1905 provides that whenever any female insane patient is to be removed from any county almshouse to a state hospital or asylum for the insane, or from one state hospital or asylum for the insane to another state hospital or asylum for the insane, or from the home of such insane patient to an almshouse, hospital or asylum, or when returned from such institution to her home, it shall be the duty of the court under whose order such patient is committed, or of the freeholders or commissioners of the county, or the overseer of the poor of the district to which such patient is chargeable, if not committed by the court, to provide a female attendant for every female patient in transit, at the expense of the proper county or poor district.

Adulteration with Methyl or Wood Alcohol Prohibited.

Chapter 100 of the Laws of New York of 1905 amends Section 165 of the agricultural law by adding the provision that in case of food an article shall be deemed to be adulterated if it contains methyl or wood alcohol, in any of its forms, or any methylated preparation made from it. Chapter 122 amends the public health law by adding to Subdivision A of Section 41, relative to adulterations, the provision that, in case of drugs, an article shall be deemed to be adulterated if it contains methyl or wood alcohol, in any of its forms, or any methylated preparation made from it. It also adds a similar provision with regard to food, under Subdivision B, while Subdivision C, relative to spirituous, fermented and malt liquors, and Section 46, relative to wines, are made to declare against their adulteration with methyl or wood alcohol in any of its forms.

Disclosure of Professional Information.

Chapter 331 of the Laws of New York of 1905 amends Section 834 of the code of civil procedure to read as follows: A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient, in a professional capacity, and which was necessary to enable him to act in that capacity; unless, where the patient is a child under the age of 16, the information so acquired indicates that the patient has been the victim or subject of a crime, in which case the physician or nurses may be required to testify fully in relation thereto on any examination, trial or other proceeding in which the commission of such crime is a subject of inquiry. Nothing in this act contained shall affect any actions or proceedings now pending. This act shall take effect Sept. 1, 1905.

Commitment Authorized of Users of Narcotics.

Chapter 3 of the Public Laws of Maine of 1905 provides that a person alleged to be suffering from the effects of the use of an opiate, cocain, chloral hydrate, or other narcotic may be committed to the care of any general hospital receiving aid from the state, or any legally qualified physician of not less than five years' actual practice, for treatment; and the medical authorities of said hospital or said physician to whom said patient is committed shall have the power and authority to restrain said patient so committed in such manner as may be necessary for his protection for a period not exceeding ninety days. But before any restraint shall be imposed under the authority of this act, a voluntary agreement shall be made in writing by the person suffering from the effects of any drug above mentioned, to the imposition of restraint on his actions, if necessary, and such agreement must be witnessed by the husband, wife, or parent of the person aforesaid, or one of the muncipal officers of the city or town in which the person, suffering as described in this act, is a resident, and approved, after reasonable notice, by a justice of the Supreme Judicial Court or a judge of the Superior Court or Probate Court in the county where the patient resides. Any justice of the Supreme Judicial Court, or a judge of the Superior Court or Probate Court in the county where the patient resides, may, at his discretion, require the president or secretary of the state board of health, or one of the county examiners of insane criminals, to investigate as to the progress of any such case; and, on his certificate that further restraint is unnecessary, may annul the agreement, and the person restrained shall be immediately released on the order of said justice.

Provides for Destroying Mosquito-Breeding Areas.

Chapter 80 of the Laws of New Jersey of 1905 is: "An act to provide a method for locating and destroying mosquito-breeding areas, authorizing appropriations for said purposes and providing state aid for freeing salt-marsh areas from mosquitoes." It provides that it shall be lawful for the mayor, or executive officer, or the board of health of any city, borough, incorporated town, village, or the governing body or board of health of any township or county to make request in writing to the director of the agricultural experiment station in the state, or to the person appointed by said director for the purposes of this act, to investigate, or cause to be investigated, the source of breeding places of mosquitoes which may or do infest said city, etc.; and it shall be the duty of such director, or the person appointed by him, as soon as may be, to investigate, or cause to be investigated, the source or breeding places of such mosquitoes, and he shall as soon thereafter as possible report to the officer or body making such application the results of the investigation made, and also the measures that should be adopted to destroy such breeding places, or render them free from future mosquito breeding. Whenever an investigation shows that the mosquitoes infesting the community and causing the nuisance complained of are those breeding on the salt-marsh areas within the jurisdiction of any city, etc., and a copy of the report shall be sent to the board or boards of health of the municipality or municipalities in which the breeding places are situated, attaching statements specifying the localities affected by the marsh-breeding areas, the extent of the dangerous area, the character of the work necessary to prevent further mosquito breeding and the probable cost of the work required in each municipality, the governing body of the municipality may, on the written request of its board of health, appropriate 75 per cent. of the sum required to complete the work, and the director of the agricultural station may, out of money appropriated by the state for this purpose, together with the appropriation of such municipality, complete the work; provided, that not more than $500 from said state aid appropriation shall be expended in any one municipality in any one year.

More About Alcoholics Labeled as Medicines.

Internal Revenue Circular No. 676, issued by Commissioner Yerkes under date of Nov. 24, 1905, states that since the ruling of Sept. 12, 1905, in Circular No. 673, reported on page 1025 of The Journal of Sept. 30, 1905, was made, manufacturers of preparations referred to in that ruling and wholesale druggists and retail druggists handling them have demonstrated that large losses would occur to them if the ruling was made effective on Dec. 1, 1905. They said that in good faith and under rules heretofore controlling they had purchased these compounds in large quantities, had them in stock, and that it would be impossible to dispose of them by the date originally stated. After careful consideration of this phase of the case, and to protect those who in good faith had engaged in the sale of these preparations, this office has determined to make the order effective as against manufacturers on Jan. 1, 1906, instead of Dec. 1, 1905. With regard to all handling these preparations as retail dealers, both druggists and other merchants, the order will be made effective April 1, 1906, the beginning of the last quarter of the current fiscal year.

It is further stated that it was the purpose to make public announcement before Dec. 1, 1905, of the various preparations found by analysis to be within the terms of the ruling of September 12. By reason of the care given in making analyses of these compounds the office has been unable to complete the examination of all such compounds now on the market. However, it has made analyses of the following preparations and finds that they are within the terms of the ruling of Sept. 12, 1905: Atwood's La Grippe Specific, Cuban Gingeric, De Witt's Stomach Bitters, Dr. Bouvier's Buchu Gin, Dr. Fowler's Meat and Malt, Duffy's Malt Whisky, Gilbert's Rejuvenating

Iron and Herb Juice, Hostetter's Stomach Bitters, Kudros, Peruna, Rockandy Cough Cure. This office will continue to make analyses of other preparations similar to those already examined, and will announce from time to time the conclusions reached. Until public notice is given as to other preparations than those above named, manufacturers of same, druggists, and others handling these preparations will not be held liable for special tax for other articles than those set forth herein, provided that the compounds are sold in good faith as *medicines.*

1 *Results of the Open-air Treatment of Surgical Tuberculosis. W. H. Halsted, Baltimore, Md.
2 **Action of the Roentgen Rays on the Blood; An Experimental Study.* R. S. Morris, Ann Arbor, Mich.
3 *Speech Training as a Factor in the Development of the Feeble Minded. G. H. Makuen, Philadelphia.
4 Value of Chloretone and Sulphonal in the Treatment of Insomnia. J. S. Christison, Chicago.
5 Approximate Measures of the United States Pharmacopeia. M. I. Wilbert, Philadelphia.
6 *Aseptic Management of the Umbilical Cord. J. T. Schell, Philadelphia.

1. Open-air Treatment of Surgical Tuberculosis.—Halsted refers briefly to the open-air treatment of surgical tuberculosis on the "bridge" of the Johns Hopkins Hospital, and describes in detail the splendid results obtained by the open-air treatment of private patients. He says that most patients with surgical tuberculosis will recover without operation if they are given a fair opportunity in the open air. Halsted questions the necessity and wisdom of overfeeding and the value of tuberculin as a means of deciding when to discontinue fixation and to permit the use of the affected joint. He is of the opinion that a definite reaction probably could be obtained in all so-called cured cases. He says that it is the surgeon's duty not only to advise out-of-doors living, but to see that his instructions are carried out as it was intended they should be.

2. Action of Roentgen Ray on Blood.—Morris has undertaken the study of the more immediate effect on the blood of moderately long, continuous exposures to the Roentgen ray. He epitomizes his results in the following conclusions:

> 1. The Roentgen rays cause a marked diminution in the absolute number of leucocytes in the peripheral circulation.
> 2. Preceding the leukopenia, there may be a moderate rise in the number of leucocytes from 8 to 12 hours after the exposure, the increase being due largely to the greater number of polynuclear cells in the circulation (observed only in the rabbit); the same condition may be found just at the end of the exposure, subsiding rapidly.
> 3. The lymphocytes are especially susceptible to the action of the rays; they are affected first and most intensely.
> 4. Alterations in the histologic characters of the lymphocytes and polynuclear amphophiles may be found in the rabbit, similar to those described in the lymphoid tissue and bone marrow.
> 5. Hard tubes produce the most marked changes in the leucocytes.
> 6. No noteworthy numeric or histologic alteration takes place in the red blood cells within the first few hours following exposure; the percentage of hemoglobin is not essentially affected within the same time.

3. Speech Training as a Factor in the Development of the Feeble-minded.—Makuen considers defective speech a physical and mental sign of feeble-mindedness, and that it may be the cause as well as the result of feeble-mindedness. He refers to the case of a boy who was thought to be feeble minded, and who is now a successful business man as the result of the removal of some mechanical obstructions to the normal development of the organs of speech and the correction by training of the faulty mental and speech habit. Other cases are cited to illustrate the difficulties of diagnosis and prognosis.

6. Aseptic Management of Umbilical Cord.—Schell describes a method used by him for some time which entirely does away with the old infected and rotting stump. As soon as the child is born the umbilical cord is clamped with a hemostat about three inches from its abdominal attachment; another hemostat is then placed a short distance from the first one toward the placental end of the cord, and the cord is then cut between. The child is now wrapped in its aseptic receiving blanket and placed to one side, and the whole attention is given to completing the delivery of the mother, including possible repairs of perineum, etc. After the third stage of labor is completed the vessels in the cord, as a rule, have ceased pulsating. The cord and abdominal wall immediately surrounding it are carefully washed in a 1 to 4,000 mercuric chlorid solution. The hemostat is then grasped in the left hand, and a pair of scissors in the right hand follows the skin amniotic junction until this is severed completely in its entire circumference. Care must be taken not to cut too deeply, as the vessels of the cord are usually very close to the amniotic covering. Schell says that even if they are cut, no serious hemorrhage will result, as the circulation, as a rule, by this time has practically ceased through these vessels. As soon as the vessels have been exposed, the amniotic covering and the Wharton's jelly are stripped away in a direction from the abdominal walls and a ligature consisting of a piece of very fine (No. 0) sterile catgut is then thrown around the vessels, and the cord is severed close to the ligature. The stump is washed in mercuric chlorid solution, dried with a piece of sterile gauze, and dusted with any good antiseptic dusting powder. The baby should not be put in the tub for about a week, but should be given a lap bath; the stump must be washed frequently in a boric acid solution, and a small amount of dusting powder used with the usual sterile pad and the abdominal bandage.

7 *System of American Hospital Economy. A. G. Gerster, New York.
8 *Essential and Paroxysmal Tachycardia. J. J. Morrissey, New York.
9 *Subcatabolic Mechanism Involved in the Etiology of Common Colds. H. Wakefield, New York.
10 *Test Feces; Their Value in the Recognition in Intestinal Disturbances Taking Their Origin in Other Parts of the Digestive Tract. H. Stern, New York.
11 *Medical Education. E. Castelli, New York.
12 *Valvular Closing of the Gall Bladder After Operation. H. E. Rockey, Portland, Oregon.

7. American Hospital Economy.—In analyzing the conditions which underly the extravagance and waste in hospital management in this country, Gerster emphasizes the necessity for more active participation in the executive control by the members of the hospital staff. The plans or organization of the great hospitals of Hamburg, Berlin, Vienna and Budapest are described in detail, the essential features being that the position of the lay superintendent of American hospitals is occupied by one or more salaried medical directors, the attending staff is very limited, so that the service is a permanent one with salaried visiting physicians and surgeons, and the house staff also is composed of paid assistants, whose positions are permanent. In this way all those concerned are able to give the necessary time to details of economical management, and also acquire the experience necessary to carry them out with effect. The present plan of conducting hospitals here resembles that in use in medieval Europe, and the author predicts that sooner or later a system similar to that now employed in Europe must be adopted.

8. Tachycardia.—Morrissey classifies tachycardia under two main heads—essential and paroxysmal, and two subheads—true and false. Permanent disease of the heart muscle best illustrates true tachycardia. The false variety, he says, may be produced by causes far removed from the heart. There are certain definite peculiarities which distinguish true tachycardia from the evanescent "heart hurry" so frequently produced by the most trivial causes. 1, The attack is sudden in its onset, reaching its height almost immediately; 2, the patient may or may not be entirely unconscious of the great degree of palpitation; 3, there is generally a definite period covered by the attack; 4, the reversion to the normal condition is as sudden as the onset, the vestiges of the storm through which the patient has passed rapidly disappearing. Morrissey concludes by saying that the treatment of tachycardia is that of the condition from which it arises or with which it is associated, but it must be remembered: 1, That essential tachycardia is not accompanied with indigestion; 2, that paroxysmal tachycardia and the forms of tachycardia, accompanied by signs, no matter how slight, of Basedow's disease, are very frequently associated with dyspepsia; 3, that extreme cardiac arrhythmia frequently occurs without any indication of stomach disease, and, 4, that tachycardia in its various grades is, however, often but a symptom, a prominent expression of a neuropathic state, which requires to be approached for treatment from many sides.

9. **Subcatabolic Metabolism of Colds.**—According to Wakefield, colds represent the results of disorders of metabolism due to local circulatory disturbances following the unusual exposure to cold of some part of the body. The degree of temperature is subordinate to the state of inequality produced, for a cold may be due to the extrinsic effect of either cold or heat, if sufficiently pronounced or abrupt to insure a localized action of definite heterogeneity from the balance of the organism. Wakefield has discovered that protoplasm as such is subject to the general laws that heat causes expansion and cold contraction, or, in other words, cold heightens, and heat lowers the specific gravity of protoplasm in general, not excepting that of the parenchyma. In analyzing the mode of origin of a common cold Wakefield says that primarily a condition of disequilibrium is produced. An individual, during a period of normal heat balance, gets wet, cold feet; a state of contraction of the tissues of the lower extremities is attained, the blood is ejected from the peripheral vascular areas to the more roomy reservoirs of the splanchnic veins, which readily dilate to receive it, with the result that a pernicious splanchnic venous stasis is produced, concurrent with a capillary and arterial blood deficiency in the extremities and with an inevitable suboxidation of the dependent tissues in the extremities.

10. **Value of Test Feces in Diagnosis.**—Stern discusses the alterations produced in the stools in cases of intestinal disorder associated with gastric, hepatic or pancreatic disease. He believes that many of the transitory and milder intestinal disturbances are the result of gastric disease. Stern says that according to the extent and duration of the secondary, or intestinal affection other pathologic elements may be found admixed with the fecal masses, but the exhibition therein of large amounts of connective tissue fragments invariably points to the gastrogenous causation of the intestinal disturbance, no matter how completely the phenomena due to the latter may overshadow all subjective gastric symptoms. Disturbances of intestinal function are much more rarely the consequence of hepatic than of gastric disease. Almost all hepatogenous intestinal affections are caused by disordered biliary secretion. Stern says that biliary obstruction underlies the intestinal disorder when the test feces, 1, are excreted in very large quantities; 2, when they present a grayish-white color; 3, when the sublimate test is negative; 4, when considerable masses of the ingested fat reappear; 5, when very large amounts of fatty acid flakes can be demonstrated, and 6, when there are no pathologic amounts of other food débris present. The test feces in cases of pancreatic degeneration, contain similar amounts of fat, as those in biliary obstruction. They differ, however, from the latter: 1, by not being excreted in such large amounts; 2, by exhibiting normal quantities of biliary pigments; 3, by containing large quantities of muscle débris, which are macroscopically recognizable; 4, by frequently presenting its fatty contents in the form of globules of neutral fat, when examined under the microscope; 5, by the occasional exhibition of putrefactive changes.

11. **Medical Education.**—Castelli says that the medical student must be of mature age when he enters on his medical studies, because the lad of 22 has not the insight into the problems of life that is necessary in order to give his patient moral support and assistance as well as drugs. It is the lack of the power of mental dominance in physicians that has given to christian science and other "pathies" the position they hold. The physician should also be of the male sex, for woman, in addition to her physical infirmities, is handicapped in the practice of medicine by the fact that she is violating the fundamental principles of her being. Women have done and are doing splendid work in the profession, but it is at a mental and physical price which it is a pity that any woman should be compelled to pay. The physician furthermore in his own physical condition must be able to set an example to his patients and to make his own atmosphere one of physical rationalism. Culture and high moral qualities are also necessary to make the physician what he should be—the most tolerant of men, a man whose faith in mankind never wavers, who never permits his poise to be disturbed by the unworthy things of life or its disappointments, a man who believes in doing good and does it.

12. **Valvular Closure of Gall Bladder.**—Rockey has devised a plan of introducing the drainage tube into the gall bladder after cholecystotomy, which is intended to prevent the prolonged leakage of bile. The tube is inserted through the incision into the gall bladder, which is surrounded by a purse-string suture of catgut. The edge is turned in so as to bring the peritoneal surface into contact with the tube, and then a second purse string is placed about the first. On tightening this the first suture is invaginated into the gall bladder and a valve is formed varying in size according to the distance between the two sutures. The drainage tube should be fastened to the skin by anchor stitches of silkworm gut, to prevent the tension on the purse strings and consequent puckering of the valve. This is best done by passing a silkworm gut stitch at either side of the tube and tying a small loop above the first knot. A similar tie and loop of silkworm gut is made around the tube about one inch from the skin. A safety pin is then passed through the three loops, thus holding the tubes firmly in place. A firm dressing is applied and a bottle suspended from the bandage over the tube.

17 *Studies in [illegible] P. Ravenel and H. R. M.
18 Substitutio[illegible] the Physician's Prescript[illegible] N. Y.

14. **Relation of Parathyroids to Paralysis Agitans.**—Berkeley discusses the clinical relationship of absence of the parathyroids or of disturbed function of these glands to disease, and whether such disease can be cured by the administration of the dried extract of the glands. Personally he believes that atrophy or insufficiency of the parathyroid glands is, perhaps, the cause of paralysis agitans. He has administered a physiologically tested gland in 11 cases of shaking palsy in all grades of advancement. All the patients remarked on a curious increase in courage, comfort and mental energy while taking the remedy. Berkeley states emphatically that the product used should be tested physiologically beforehand and should be kept on ice till used. The initial dose of the powdered gland is one-twentieth of a grain, from two to four times daily, preferably given in a capsule; larger doses appear to produce weakness, constipation, nervousness and even an exaggeration of the symptoms of the disease. The first good effects in the patients treated were noted, as a rule, only after from 50 to 75 capsules had been taken. Nine of the patients so treated were helped; one considered himself entirely relieved while taking the remedy. In all the earlier cases the patients were greatly helped. Berkeley believes that when a more perfect form of medication is devised the results may prove more encouraging.

17. ***Agglutination* in Tuberculosis.**—Studies in agglutination made by Ravenel and Landis for the purpose of determining whether the reaction is of any prognostic significance in tuberculosis, and whether the resistance of the individual is increased by the hygienic and dietetic means now employed, showed that the agglutination test is not available for diagnostic purposes, and that the more advanced the disease, the lower is the agglutinating power. Patients living under favorable conditions, as at a sanatorium, have the agglutinating power distinctly increased. A low agglutinating power is of unfavorable prognostic significance. The technic employed is as follows: From 5 to 10 c.c. of blood were drawn from a vein at the bend of the elbow. The blood was allowed to stand for twenty-four hours, when the serum was drawn off and dilutions were made with a homogeneous culture of tubercle bacillus in proportions of from 1 to 5 up to 1 to 100. The homogeneous culture was grown from twelve to fourteen days in 5

per cent. glycerin-bouillon, then formalin was added in proportion of 1 to 1,000. The tubes containing the culture and serum were observed every two or three hours, but the final reading was made at the end of twenty-four hours. A positive result consisted in a clearing of the supernatant fluid, or the agglutination of small whitish clumps, usually at the bottom, but occasionally along the sides of the tube.

25 Nephritis and Hematuria. (Concluded.) H. A. Fowler, Washington, D. C.

21. **Extrauterine Pregnancy.**—Noble has operated in 91 cases of ectopic pregnancy—in 89 by abdominal section and in 4 by vaginal incision, 2 of these requiring subsequent abdominal section. In this series one tube was involved about as often as the other. In twenty women the opposite Fallopian tube was inflamed, the conditions present being salpingitis, hydrosalpinx and hematosalpinx. In no case was a pyosalpinx present on the opposite side. Noble says that this evidence tends to support the view that infection, of mild type, of the tube is a prominent cause of ectopic pregnancy. Noble believes that the causes of ectopic pregnancy are mechanical, due either to infection of the tube, to congenital defects in the tube, or to mechanical distortions which in some way prevent the onward progress of the impregnated ovum. Seven of the patients are reported as unruptured, 13 as ruptured, and 71 as having tubal abortion. Rupture of the tube, with resulting free hemorrhage, occurred in 14 cases. Tubal abortion, complete or incomplete, occurred in 70 cases. In cases of extrauterine pregnancy like those under consideration, Noble advises immediate operation. Light anesthesia, rapidity in operating, the ligation and removal of the affected appendage, the removal of the larger masses of blood clots manually, the removal of a portion of the free blood contained in the abdomen by irrigation with salt solution poured into the abdomen from a pitcher, the dilution of the remainder by leaving the abdomen filled with the salt solution, and the rapid closure of the abdominal wound without drainage, are the characteristics of the operation which, in his judgment, offers the patient the best chance for recovery. Refinement in technic in this group of cases is to be deprecated. The deeper anesthesia necessary, the loss of time entailed, and the additional handling of the viscera will make the shock already present more severe, greatly increasing the prospect of a fatal result. The freest hypodermic stimulation with strychnin, digitalis, and camphorated oil, and the use of salt solution by hypodermoclysis before, during, and after operation, are indicated. Tubal abortion, Noble says, demands prompt abdominal section, the removal of the appendage involved, the careful removal of the blood clots, toilet of the pelvis and peritoneum, and the closure of the abdominal wound *secundum artem.* Drainage is not called for. Existing complications must be dealt with as indicated. When the opposite appendage is diseased and its removal required, it is often simpler to perform a supravaginal hysterectomy rather than a bilateral salpingo-oöphorectomy. If the vermiform appendix is adherent to the hematocele, as is frequently the case, unless the condition of the patient forbids, it should be removed. In the exceptional cases in which a large amount of blood has been lost and the condition of the patient is serious, the question will arise as to whether operation shall be immediately performed or postponed until improvement has occurred. The proper course depends on whether hemorrhage is continuing or has ceased, and also on whether the patient is so situated that the operation can be performed immediately, should evidences of recurring hemorrhage become manifest. Errors should be made on the side of prompt operation rather than on that of undue waiting. When the condition of the patient is extreme from shock and excessive hemorrhage, the rules for operation in tubal rupture apply in dealing with tubal abortion. Noble's experience with extrauterine pregnancy has impressed on him two lessons: 1. A correct and early diagnosis can usually be made if the history of the patient is carefully elicited. The diagnosis depends as much on the history as on the results of physical examination. 2. If an early diagnosis is made, the patients can be operated on while still in good or fairly good condition, with the result of securing a high percentage of recoveries. Deaths from extrauterine pregnancy are usually due either to the occurrence of hemorrhage so sudden and profuse that the patients are *in extremis* before operation can be performed, or else they are due to failure to make a diagnosis or to unwarrantable delay in resorting to operation.

28 Rupture of the Intestine. F. B. Lund, Boston.
29 Malignant Disease of the Lungs and Pleura. H. Jackson, Boston.

27. **Alkaline Treatment of Diabetic Coma.**—Sears reports the case of a boy, 13 years old, who was treated successfully during an attack of diabetic coma by the administration of large quantities of alkalies. Immediately after his admission to the hospital, the patient was given eight ounces of sterile salt solution, containing bicarbonate of soda almost to the point of saturation, under the skin of each breast. A solution of the same drug, in the proportion of a heaping teaspoonful to the tumbler, was given by mouth to the limit of his capacity. No record of amount was kept, but, as he was very thirsty, large quantities were taken. His stupor rapidly decreased, but he remained drowsy for several days. In spite of the large doses of alkali given, the urine remained persistently acid. Sugar varied between 1 per cent. and nearly 3 per cent. under a diet which contained a little bread and considerable quantities of milk. Acetone was more frequently present in the urine than absent. The only complication of note was the occurrence of suppuration at the site of the hypodermic injections. The injections were given by means of a glass flask used as a fountain syringe. Palpation of the suppuration gave the sensation of an air cushion, and crepitation was present. The patient made a complete recovery.

38 Value of Early Diagnosis in Ulcerations of the Anorectal Region. L. J. Hirschman, Detroit.

34. **Sterilization and Absorbability of Catgut.**—This paper presents the results of the attempts made by the authors to put on a demonstrative basis the questions: (1) As to what are the best materials for ligatures or buried sutures; (2) which is the easiest and at the same time the most reliable method of sterilization, and (3) what is the durability of absorbable material when buried deeply in the tissues. Experiments conducted under the supervision of Nancrede show that sterilization by the Claudius method is entirely reliable. Strands of No. 2 catgut, wound on glass rods and pieces of large white silk, were used. The catgut and silk were immersed in an emulsion of cultures of anthrax in sterile water for 24 hours at room temperature. The Claudius solution was made by grinding together one gram of pure iodin crystals and one gram of potassium iodid and adding 100 c.c. of distilled water. The silk and catgut were immersed in the Claudius solution and removed at stated intervals. It was found that the iodin carried over on the suture material prevented the growth of anthrax spores until sufficiently diluted. That silk and catgut, soaked in an emulsion of anthrax spores

for 24 hours and thoroughly dried, are rendered free from living organisms by at most from 2½ to 3 hours' immersion in the Claudius solution. Pieces of coarse cotton grocer's twine were soaked for 24 hours in emulsions made up of distilled water and potato cultures of anthrax, potato and hay bacilli, all showing abundant spores. Cover-glasses were also smeared with these same potato cultures, both twine and cover-glasses were afterward very thoroughly dried in the incubator. Both pieces of twine and cover-glasses grew their respective bacilli when put, untreated, into tubes of beef tea. The pieces of twine and cover-glasses so prepared were all immersed in the Claudius solution and removed at intervals. These experiments demonstrated that heavy cotton grocer's twine, soaked for 24 hours in an emulsion of the spores of anthrax, hay or potato bacilli, and thoroughly dried, is rendered free from living organisms by at most 24 hours' exposure to the Claudius solution, and that cover-glasses, smeared with potato cultures of anthrax, hay or potato bacilli containing spores, and thoroughly dried, are rendered free from living organisms by at most 24 hours' exposure to the Claudius solution. The first tensile-strength experiments showed the following: 1. Tight winding of the gut markedly affects the gut physically and reduces the tensile strength. 2. Solutions of iodin and potassium iodid do reduce somewhat the tensile strength of the gut. 3. More dilute solutions do not obviate this drawback, except the most dilute examined, which is probably not sufficiently germicidal. 4. Alcoholic solutions preserve or increase the tensile strength, except in dilutions which require the addition of potassium iodid to put the iodin in solution. 5. With a knot in the continuity of the gut, greater tension was almost invariably necessary to break the iodin gut than the wet, untreated gut. 6. The iodin gut is apparently somewhat more elastic than the wet, untreated gut. The second series of tensile-strength experiments showed: 1. The tensile strength of No. 1 gut is lowered by exposure to the Claudius solution, more so in case it has previously been exposed to formalin. 2. Certain pieces of gut are absolutely worthless as ligature or suture material after exposure to the Claudius solution. 3. With a knot tied in continuity the relative loss of strength is much less. 4. In replacing unused gut in the Claudius solution, aseptic gut only must be replaced, as the iodin was present in the solution in less than one-eighth its original strength. The gut must be kept in a glass-stoppered bottle, tightly closed.

40 End Results in Surgery of the Kidney. A. Vander Veer, Albany.
41 *Actinomycosis Limited to the Urinary Tract. D. MacD. Stanton, Albany.

41. Actinomycosis Limited to Urinary Tract.—The case reported by Stanton was clinically one of cystitis and pyelonephritis. The actinomycotic character of the kidney lesion was not recognized during life nor at the time of the autopsy, but was discovered on histologic examination of the kidney. About two months before his death the patient began to have difficulty in passing urine. He could pass only a small amount at one time. For some time before admission he had been troubled with incontinence. The urine was low in specific gravity, 1010. The blood examination showed a hemoglobin value of only 45 per cent. There was no leucocytosis. While in the hospital the patient had an irregular temperature ranging from 99 to 103, and was slightly irrational the greater part of the time. The treatment was purely symptomatic. A histologic examination of portions of the kidneys containing abscesses disclosed colonies of actinomyces. The mode of infection in this case was doubtful, but Stanton suggests that it is more than possible that the lesion in the urinary tract was secondary to a primary focus which had existed in some other part of the body, but which had disappeared at the time of the autopsy. A small scar-like area in the colon, suggesting a healed ulcer, various peritoneal adhesions and an old scar on the outer aspect of the right thigh, each suggested antecedent inflammatory conditions offering possible routes of infection, but no connection could be traced between any of these and the lesion in the urinary tract.

44 *An Adjunct to the Fresh-air Treatment of Consumption. G. T. Carpenter, Chicago.

44. Adjunct to Fresh-Air Treatment for Consumption.—There are many reasons, says Carpenter, why persons suffering from pulmonary tuberculosis can not leave their homes for a more suitable climate. To give such patients all the fresh air possible and still permit them to remain indoors, Carpenter devised an apparatus of simple construction, which consists of tubes large enough for the passage of air at normal air pressure, and light enough to be easily handled. The face piece, or mask, can have a transparent front, and is supported by a net cap, which will hold it firm in all positions. Large valves control the passage of air. The tubes are composed of coiled aluminum wire, covered with a light fabric which is impervious to air. These tubes are conducted to a panel which is fitted in an open window, with a suitable aperture to receive it, and a protecting hood on the outside. Openings can also be made through the outside wall of a bedroom to the outer air, choosing a side where the sun shines. The tubes may be detached from the opening, and the opening closed, and the apparatus can be carried to another part of the house and attached to an opening through the wall or paneled window. The mask is so arranged that it can be detached from the net cap, which is convenient in case of a desire to cough or to expectorate. The inhalation tube can be large and contain the exhalation tube, so that but one tube is in sight, and yet all exhalations are carried to the outside of the house. With this contrivance it is possible for patients to have fresh air, no matter what the state of the weather. They can also enjoy a sun bath in a superheated room, if desired, and inhale fresh air at the same time.

51 Conservative Treatment of Trachoma. E. D. Capps, Ft. Worth.

46. Penetrating Wound of Eyeball.—The feature of special interest in Hayden's case was the fact that the eye which was so badly injured as to seem hopelessly lost should recover itself with comparatively little inflammatory reaction. The patient had been struck in the left eye by a flying projectile, presumably glass, from an exploding oil-carrier. After cleansing the eye, there was seen to be a somewhat vertically placed wound in the conjunctiva and sclera to the nasal side of the cornea. The margins of the wound were ragged, and its shape was that of an obtuse angle, with its apex pointing toward the cornea. The contraction of the internal rectus muscle made the wound gape. There was some blood in the anterior chamber and cloudiness of the anterior part of the vitreous. No foreign body could be found. The scleral wound was closed by one silk suture and the conjunctiva was brought together over it by two sutures. Twelve days after the injury it became necessary to make an incision with the keratome in the lower part of the cornea to allow the blood to flow out from the anterior chamber. The case went on to complete recovery, the patient regaining useful vision.

9 Case of Traumatic Asphyxia. W. S. Robertson.

1. Operative Treatment of Fractures.—Lane discusses the treatment of simple fractures devised by him thirteen years ago, and cites illustrative cases.

4. Influence of Posture on Heart.—Gordon is of the opinion that the change in the normal heart sounds produced by change of posture may be explained, in part, at least, by the different relations of the valves to the weight of blood in contact with them in the different positions. An examination of 36 consecutive unselected cases with normal hearts showed that posture also affects the deep cardiac dullness, although in a very small number of cases the over limit of dullness rises instead of falls.

5. Aid to Prognosis in Typhoid.—For the last nine years Simon has made daily observations of the amount of urine passed by every patient suffering from enteric fever. He found that polyuria occurred not only in every case that was doing well, but also in many cases of great severity in which no general improvement or amelioration of symptoms could be observed. He also found that even in severe cases, if polyuria occurred, the patients all recovered. In no cases in which polyuria was noted has he known perforation to occur, and in no case has hemorrhage of any moment ever occurred after polyuria had been established. Furthermore, relapses occurred only rarely when polyuria had once begun.

7. Parangi.—In 7 out of 11 cases of parangi Castellani found spirochetes, one variety being identical with the organism described by Schaudinn. Peculiar oval, chromatin-containing bodies were also observed in 4 cases, 3 among those presenting spirochetes. Castellani does not offer any suggestion as to the identity of these bodies.

11. Operation and X-Rays in Breast Cancer.—Sheild operated on a woman aged 46 for an advanced hard carcinoma of the breast. The axillary lymph glands were removed as well as the lower portion of the pectoral muscle. Although the wound could not be closed, healing progressed satisfactorily. Four months later there was evidence of a recurrence in the intercostal spaces. Eight or ten nodules were removed, and two months afterward six more nodules were removed. A fourth operation was done three months afterward. The patient's condition remaining unfavorable, *x*-ray treatment was advised. In addition the patient was ordered to take 5 grains of quinin hydrochlorate on the mornings of the days of the *x*-ray applications. For two months *x*-ray applications were made twice a week; then once a week. Within three weeks from the commencement of the treatment the patient's condition improved, and at present she is quite well. There is no sign of carcinoma. The *x*-ray applications were of twelve minutes' duration, the tubes used being soft or of medium hardness, and the current between 0.5 and 0.8 mp. The surrounding parts were not screened except the face, arm and forearm. There was no dermatitis or pigmentation.

23 Diagnosis of Peritonitis in Enteric Fever. F. Macrae.
24 Surgical Aspects of Enteric Fever. T. K. Dalziel.

19. **Radical Cure of Inguinal Hernia.**—The method of operating followed by Nicoll is applicable to both femoral and inguinal hernia. Its main features are: 1, The employment of the sac to form an intra-abdominal buttress over the internal aspect of the hernial aperture; 2, the use of the pubic ramus as a *point d'appui* in the process of closure of the hernial canal, and 3, the additional security of closure obtained by the superposition on the bone sutures of a plane of musculo-fascial sutures. In ordinary cases Nicoll says that his method gives results as good as, but no better than, many of the other methods in use. In severe cases—cases of large hernial aperture, or lax and atrophic parietes, or high intra-abdominal tension from omental corpulence—the method, with its double closure of the canal, by bone suture, followed by musculo-fascial sutures, attains a high degree of security. One of the main ideas concerned in the application of this method of inguinal hernia is to reinforce in such cases the defective Poupart's ligament by the backing of the pubic ramus. The treatment and final bestowal of the sac are carried out as in femoral hernia, the sac being lodged over the internal aspect of the internal inguinal ring, as a pad resting between the parietal peritoneum, on the one hand, and the fascia transversalis on the other. With blunt retractors the spermatic cord (or round ligament) is pulled upward, and Poupart's ligament downward. An incision is carried along the superior aspect of the pubic ramus. This divides the iliac fascia, the origin of the pectineus, and the periosteum; its limits are the pubic spine and the femoral sheath. Both margins of the periosteal wound are slightly detached. The bone is then drilled near its upper margin in two places, from half an inch to one inch apart. The drill-holes are situated somewhere between the pubic spine and the femoral sheath, their exact position varying with the shape and size of the hernial aperture. The drill may be applied to the bone above the level of the retracted Poupart's ligament in cases in which that is sufficiently lax to afford the necessary room for passing the drill transversely through the bone. In cases in which that is not so, the drill should be applied to the anterior surface of the bone, below the level of Poupart's ligament, and, in consequence, after perforating the pubic portion of the *fascia lata*. Transverse perforation of the bone is essential. Oblique perforation places the internal apertures of the drill-holes far down on the posterior aspect of the bone, and makes them more or less inaccessible. A stout absorbable ligature is passed in the form of a large mattress suture, through the internal pillar of the hernial aperture. Nicoll says that it is essential that this should have a "good bite" of the conjoined tendon and of the transversalis fascia; it may or may not include the external oblique. During the placing of the suture the peritoneum is protected by the finger passed through the canal into the extraperitoneal fat behind the internal pillar. The ends of the sutures are passed out through the holes drilled in the bone. The sutures may pass in front of the spermatic cord or behind it as may seem best to secure firm closure of the canal without undue compression of the cord. In the former procedure the cord will occupy the position of the direct inguinal hernia, in the latter that of the oblique variety. The ends of the two loops of ligature are tied separately. The tightening of the knots brings the internal pillar down into the periosteal incision, and lodges it firmly against the bone. The factor in choice of the position of both drill and ligature knots is the degree of relaxation which has occurred in Poupart's ligament. In all cases the knots should be tied firmly to lodge the internal pillar against the bone. Here the amenity of the spermatic cord is efficiently protected, as is that of the femoral vein in the femoral operation, by adjusting the position and size of the loops of suture in the internal pillar, and not by varying the tension of the knots. Should threatened compression of cord (or vein) necessitate the "replacing" of the loops, time may be saved by dividing each loop above the bone, and retaining the ends as tractors for the passage of the new sutures. The operation is completed by lifting the lax Poupart's ligament to the anterior surface of the internal pillar and fixing it there by interrupted sutures, which should be of stout catgut or other absorbable material, and should penetrate at least the external and internal oblique muscles. This final step in the operation is made possible solely by the lax condition of Poupart's ligament. It is difficult in a small hernia. The method may be modified in cases in which the operator finds himself unprovided with a drill. The anterior lip of the periosteal incision may be slightly raised, and the ends of the suture carried through it from within outward and tied there. The knot may lie above or below the level of Poupart's ligament. The operation is finished by suturing Poupart's ligament to the anterior surface of the internal pillar as described above. The closure obtained by the modified operation is less secure than when bone suture is employed, but has been found efficient.

30 (Year LXIX, No. 36.) *Invaginations de l'appendice ileo-cécal. Jalagüier and C. Monod.

30. **Invagination of Appendix.**—Jalaguier ascribes to invagination of the appendix a certain number of fatal cases of intestinal obstruction in young children. In two cases of scrotal hernia in children in which the appendix was involved he has observed that it possessed the property of vigorous contractions. At one moment soft and small, it would then grow gradually harder and larger, until it formed a stiff, curving rod, easily palpable and even visible through the walls of the scrotum. The contractions starting in the appendix were invariably transmitted to the cecum, which became hard and stiff in turn. It even seemed as if the peristaltic movements of the cecum and large intestine started in the appendix, and were propagated thence to the rest of the mechanism as the crank of the automobile starts the machinery to work. In case of disturbances in the cecum the contractions of the appendix might not be passed along; and the result would be invagination of the latter in the former. He has observed 3 cases of this kind. In the first the invagination became spontaneously reduced; in the second it was a casual discovery at an appendicectomy after subsidence of appendicitis, and in the third, symptoms of enterocolitis were accompanied by a tumor suggesting a floating kidney, which appeared and vanished at intervals. The tumor was assumed to be a recurring invagination, and the lower part of the cecum, part of the appendix and the ileocecal valve were found invaginated in the cecum, while the ileum was also invaginated to a depth of 2 cm. The patients were children from 7 to 11 years of age. Nineteen published cases of invagination of the appendix are reviewed and tabulated, and also Wallace's case in which the appendix was passed in stool, the patient having thus performed an auto-appendicectomy.

Semaine Médicale, Paris.

31 (XXV, No. 46, Nov. 15.) *Le syndrome myotonique. L. Lévi.

31. **The Syndrome of Myotonia.**—Lévi proclaims that the sarcoplasmic theory in regard to the origin of Thomsen's disease or myotonia congenita connects all the various forms of this disease while distinguishing them. This theory is based on the comparison between the myotonic syndrome and the functions of sarcoplasm, the interfibrillary substance of the striated muscles. He analyzes the literature on the subject and describes the various forms of acquired and congenital myotonia, citing typical examples of each. His arguments tend to prove that the muscular tonus, the function of the sarcoplasm, exhibits the myotonic syndrome when in exaggerated function. This myotonic syndrome may be the result of imperfect development of the muscle or of toxic or nervous irritation of the sarcoplasm.

Berliner klinischer Wochenschrift.

35 *2 Fälle von Nephritis achlorica mit vikariierender Hypersekretion des Magens (of stomach). H. J. Bing (Copenhagen).
36 *Behandlung des Schnupfens der Säuglinge und kleinen Kinder (coryza in young children). K. Vohsen.
37 Intravenöse Injektionen. T. A. Maass.

33. **Natural Immunity.**—The conclusions of Schütz's investigations are that the new-born child acquires its natural immunity by way of placental transmission. The colostrum has no protective action, and when diphtheria antibodies can be found in the blood serum, they may be entirely absent from the stomach contents. The protecting power of the child's serum is never higher than that of the mother's serum. The presence of diphtheria antibodies in the blood serum of young infants does not indicate that they are actually immune to the disease, only, at most, that their receptivity has been diminished.

35. **Nephritis with Complete Absence of Chlorids.**—Bing relates the particulars of 2 cases of nephritis distinguished by the entire absence of chlorids from the urine. When the salt in the organism accumulated to a certain point it was eliminated into the stomach by an excessive gastric secretion, and this hypersecretion always induced copious vomiting. The vomiting occurred invariably after the patients had eaten much salt. The nephritis was not very severe, and conditions were finally restored approximately to normal. The albuminuria gradually subsided, the chlorids appeared in the urine, and the attacks of vomiting ceased. The freezing point of the blood had remained normal throughout, and there was no tendency to dropsy. The exact similarity between 2 cases suggests that the syndrome observed may be regarded as a special affection. The patients were a laboring man and woman in the thirties, both previously healthy.

36. **Treatment of Coryza in Infants.**—Vohsen calls attention to the fact that coryza paves the way for otitis, gastrointestinal disturbances, pneumonia and cerebrospinal meningitis, and emphasizes the importance of treating it to ward off these secondary affections. He relieves coryza in adults by reducing pain and swelling with a solution of suprarenal extract, cocain and water, applied on a cotton-wound wire. As infants are unable to blow their nose, this measure does not help them. He accomplishes the desired purpose with what he calls the air nose douche. A rubber tube about 25 cm. long, with the nose end cut slanting, is inserted in one nostril and air is blown into the nostril under moderate pressure from a rubber bulb or the mouth. Infants and small children usually resist and scream when the tube is being inserted, and this closes the entrance into the air passages below, so that the air blown in pours out at once through the other nostril. The air douche is always given on the side that is closed the most. It is repeated before the child is fed; the secretions escape with the air and are thus blown out through the other nostril. The same procedure will be found a great help for older children when there is difficulty in blowing the nose. In one instance Vohsen was thus able to release and to evacuate in the most gentle manner a complete fibrinous cast of the nose and nasopharyngeal space in a case of diphtheria in a child of 2. The air douche is also useful for diagnosing adenoid vegetations. He has never noticed anything suggesting danger for the middle ear from the air douche. Others have advocated aspiration of the contents of the nose, but this is liable to increase the hyperemia without insuring as radical cleansing as his technic. The nasal air douche has never failed to relieve the obstructed condition of the nose in young children when the latter is due merely to an acute infection.

42. **Spinal Anesthesia with Elevated Pelvis.**—Freund had occasion to operate in 2 cases of carcinoma of the cervix requiring the elevation of the pelvis. The operation was done under spinal anesthesia induced with 0.06 gm. stovain and a little extract of the suprarenal gland and salt, the combination known as Billon's mixture. The anesthesia was complete in four or five minutes and lasted for an hour and a quarter to two hours. One of the patients showed minimal symptoms of collapse, weaker pulse, cold sweat on the face and slight groaning, but these symptoms were slight and transient. The second patient had only the two last symptoms in an almost imperceptible degree. There was no pain, and after the operation the patients were entirely free from vomiting, headache or fever, and did not present the appearance of having just passed through a severe operation. One left her bed the fourteenth day and the hospital the seventeenth. The other was so debilitated that a longer period was necessary for her to regain strength. In 5 other cases of tuberculous peritonitis, echinococcus of the mesentery, carcinoma of the ovary or myoma with carcinoma of the ovary, spinal anesthesia by this technic, with the pelvis raised, gave invariably excellent results.

43. **Bier's "Passive Congestion" in Gynecologic Practice.**—Rudolph discusses the three ways in which Bier induces artificial congestive hyperemia: by superheated air, by constricting the limb above, and by the suction of an air pump. The superheated air acts in the same way and is fully as effective as irrigation with hot water, and can be used for the same indications. He gives illustrations of the wood, asbestos and metal, bent, flaring tube which he uses when applying superheated air to the vagina. Also of the solid glass speculum with a cork plug in the flaring end, through which passes a tube from a vacuum pump. By inducing suction with the pump the parts can be seen to swell and become dark red in color. Some blood usually accumulates in the speculum. This local suction is indicated in case of inflammatory processes in the cervix or corpus uteri. The result obtained depends on the greater or less stability of the tonus of the vessel nerves. The uterus as a whole is liable to be influenced by this stimulation of the nerves. Most of the women complained of labor-like pains after the suction had lasted some time. Amenorrhea is often favorably influenced. Suction might also prove an excellent preliminary to dilatation of the internal os. It makes the tis-

sues softer, collects blood in them and renders them less sensitive. The suction speculum is merely a glass speculum, syringe and tube, and the *modus operandi* is extremely simple. The blood-drawing action of the vacuum suction suggested to him that possibly the opposite—the compression with air—might have the contrary effect and check bleeding. He tried this measure in 2 cases, filling the vagina with filtered air under pressure. This pneumatic tamponing accomplished the desired result very promptly. He does not think that there is danger of air embolism except in case of a recently delivered uterus, but still great caution should be exercised with this air tamponing. By alternating suction and compression from the vacuum pump, it might prove possible to draw down and to push up the uterus in turn, thus massaging its supporting ligaments and toning them up if relaxed.

44. Nature of Eclampsia.—Reeb has succeeded in isolating from the urine of eclamptic women a yellowish, insoluble mass which induces paralysis when injected into frogs and guinea-pigs. This substance was never found in the urine of normal parturients. He also pulverized the brains of two women dead of eclampsia and found that the powder induced progressive paralysis in rabbits. He suggests the possibility that in the organism of the pregnant woman or in that of the fetus or in the placenta, some tetanizing poison may be produced which is eliminated without disturbance under normal conditions, but which accumulates and causes intoxication in case its elimination is interfered with in any way. He suggests, as an analogy, samandarin which is a normal metabolic product of the salamander, but which has first an exciting and then a paralyzing action.

47. Varying Tonus of Uterus in Response to Intrauterine Stimuli.—Schaeffer proclaims that the varying tonicity of the uterus is due to vasomotor as well as to purely motor influences. It is a co-ordinate function. Every dilating stimulus emanating from the internal os has a regular, dilating influence, even on the non-gravid uterus. The fundus balloons out regularly on all sides and stretches upward. The grating during curettement is due to the formation of ledges by the especially strongly contracting muscularis. The uterus of nulliparæ is not capable of a high degree of relaxation. A predisposition to a high degree of relaxation is afforded by retroflexed and originally hypoplastic uteri, by those with edematous myometritis and in anemic multiparæ, in uteri after abortion with metrorrhagia and in cases of degeneration of the ovaries. The uterus in these cases may bag out or may be asymmetrically stretched. The difference may be from 2 or 3 cm. to 11 or 12 cm., and is noted when the sound is introduced into one of the horns of the fundus. The uterus should be curetted only with a blunt spoon in such cases. If it measures longer than from 12 to 14 or 15 cm., this suggests the suspicion of defective involution of the entire fundus, especially of one horn after an early abortion. Schaeffer's experience has shown further that affections of the adnexa causing metrorrhagia also induce a predisposition to a lively alternating tonus, similar to that of pregnancy, and from this up to paralysis. The sound may show a difference of from 8.5 to 10.25 cm. during a single examination of the subinvoluted uterus. Perforation may occur without the slightest sensation of resistance, and even with a wide metal dilator, but always and exclusively in the vicinity of the tubes.

48. Extramedian Symphyseotomy or Pubiotomy.—These two communications each describe 4 cases in which women were delivered by sawing the pubic bone on one side. The results, both immediate and remote, were most excellent.

50. Operation for Total Prolapse of Climacteric Women.—The main features of the technic which Landau describes are the fixation of the posterior part of Douglas' cul-de-sac to the highest part of a sagittal incision in the vagina. The operation is a kind of incomplete extirpation of the uterus with this permanent fixation of Douglas' pouch. A muscular support is retained from the rear wall of the cervix or corpus uteri or both, and the cul-de-sac is thus strengthened by resistant tissue, so that it can hold up the contents of the abdomen. The operation is a combination of an exaggeration of Wertheim's technic with almost total resection of the uterus.

54. Trauma and Multiple Sclerosis.—Grossmann describes the case of a strong, young laboring man of 28 who fell from a moderate height while cleaning a window; he was leaning against a wire which broke. He was unconscious for a short time and two days later, when examined in the hospital, exhibited a typical case of multiple sclerosis. His friends had never noticed any indications of anything abnormal before the accident, but it seems impossible for the atrophy of the optic nerve, the "intention tremor" (on attempting voluntary movements), and the differences in the knee jerks to have developed in the course of two days. The multiple sclerosis must evidently have developed in two phases. In the first it remained latent and did not interfere with the man's working capacity. With the trauma the affection entered its second, severer phase. The man did not mention the accident, and it was only learned accidentally later. The case illustrates the way in which trauma can exaggerate an existing multiple sclerosis, but it also casts doubt on the assumption that trauma alone is able to induce the affection.

55. Ligation of Ovarian and Hypogastric Veins in Puerperal Pyemia.—Haeckel comments on the 4 cases of this procedure that have been published since Trendelenburg first suggested it. Michels reported one, and Bumm has recently published another successful case. Haeckel applied it in the case of a woman of 42 who presented evidences of pyemia after the removal of a vesicular mole. The fever persisted and severe chills recurred every day, but there were no signs of metastatic suppuration and the genital findings were normal, only in the parametrium something resembling a soft worm could be felt. After two weeks of this condition he opened the abdomen on the median line, but found no indications of inflammation or adhesion; all the organs were exceptionally pale, the ovarian and hypogastric veins were visible as soft cords. The peritoneum was incised over the right ovarian vein and the vein was ligated with a fine silk thread. The incision in the peritoneum was then extended, the ureter and the hypogastric artery were drawn aside and a fine silk ligature was thrown around the right hypogastric vein. The subserous tissue was a little tougher and less easily pushed aside than in normal conditions. The veins on the left side were then ligated in the same way, the incision in the peritoneum was closed with a running suture and the abdominal wound was closed by three tiers of sutures. The next morning there was a single, comparatively feeble chill and no more for two weeks, when there was a slight intimation of one, but the general health rapidly recuperated after the operation, and in less than six weeks the patient was regarded as cured. Except for a slight, transient swelling of the right leg no local reaction from the ligatures was observed. The operation does not remove the focus, but merely prevents the deportation of infectious material from it to other parts of the body. The focus has to be absorbed, and until this is completed there is a possibility that some small collateral route may convey some of the material into the veins and thus at times induce slight temperature. The conditions are much less favorable when the pyemia is of the acute puerperal form. The process in the veins in this case is not so much thrombosis as ulceration of the vein wall, and the germs are much more virulent. In a typical case of the latter kind he performed the same operation, but it had no effect on the temperature and chills. Bumm, however, has been successful in one case of this kind. In the chronic form, in appropriate, carefully selected cases, ligation of the ovarian and hypogastric veins may cure the patient and prove an important progress in the treatment of such cases.

56. Prostatectomy.—Schlesinger's article issues from Israel's surgical service at Berlin. The suprapubic route is preferred there, as the operation is considered simpler, the middle lobes are more easily reached and the danger of consecutive incontinence is regarded as less, while it discloses stones that might be overlooked with the perineal operation. Total enucleation of the prostate was always accompanied by removal of the prostatic urethra, but it is probable that in many instances it might be possible to spare the urethra, especially when the prostate is large and hard. In such cases there seems to be a membrane of connective tissue between the prostate and the urethra. When the condition of the bladder was good, the suprapubic wound was sutured and a permanent catheter left in the bladder for the only drainage. When the urine was infected an external urethrotomy supplemented the suprapubic operation. The perineal wound always healed without a fistula. In the after treatment the patients are soon allowed to be up and about with the permanent catheter, and it is removed after a time, when conditions allow, and merely reinserted once or twice a day, rinsing the bladder afterward, allowing the urine that escapes through the wound above to trickle into the dressings. Out of 12 cases, 3 were partial prostatectomies. In 2 cases the results were excellent, but in the third there was a complicating bladder stone, and there has been retention since. Catheterization was necessary three times a day; the cystitis has now almost entirely healed. Of the other 9, one patient died three months later from pyelitis; nothing is known of a second, who still had incontinence when dismissed. Two cases were complicated with bladder stones and 2 are still under treatment. The other 4 patients urinate normally without disturbances of any kind. Malignant degeneration was evident in one of the total dozen cases.

58. **Spirochetes in Syphilis.**—Siebert examined 125 patients for spirochetes and failed to find the *Spirochæta pallida* in any of the 46 cases of superficial cancer and other affections, while he found it in 52 out of 66 cases of lues. It was not discovered in a case of malignant syphilis, while specimens were extremely numerous in a case of syphilitic rupia. It was never observed in the blood, and it failed to pass through a porcelain filter.

61. **Intubation per Os for Anesthesia Under Increased Atmospheric Pressure.**—Kuhn describes and illustrates his instruments and apparatus and a number of clinical cases in which he has applied them. The Journal has summarized in these columns from year to year his announcements in regard to his technic for introducing the anesthetic directly into the lungs through a tube, thus avoiding all the nose and throat reflexes. Since Sauerbruch invented his method of operating in the air chamber under negative pressure, Kuhn has applied this principle to his intubation technic, but uses plus instead of minus pressure for the purpose. He relates his experiments on himself and in 5 clinical cases. He regards the chloroform-oxygen anesthesia induced by introducing the anesthetic and oxygen directly into the lungs, as a great advance in surgery.

72. **Research on Beriberi.**—Dürck has been making a special study of tropical pathology in the Dutch East Indies. He remarks in regard to beriberi that although we are still ignorant of the agent causing in such a brief space of time such havoc in the nervous and muscular systems, yet one point seems to be established, namely, that the causal agent can not be a living animal or vegetable organism. Until the veil is lifted further, there seems to be little prospect of a rational and successful method of treatment.

73. **Action of Artificial Edema in Bier's "Passive Congestion" Therapy.**—Joseph remarks that the importance of edema as a prominent factor in inflammation has only recently been realized. In the passive, congestive hyperemia induced by constriction of the limb, the edema that forms is static. He measures the amount of the edema by the displacement of water when the limb is placed in a cylinder of water, before and after the constriction. A float on the surface rises, with the water, along a graduated scale in the side of the cylinder. Each cm. that it rises represents a displacement of 200 c.c. The arm of one patient displaced 1,900 c.c. before constriction and 2,750 c.c. after twenty-two hours, showing an accumulation of 850 c.c. of edema in the arm. After removal of the constricting band and suspension of the arm, the displacement was reduced to 2,300 in three hours, showing that 450 c.c. of fluid had passed out of the arm. The displacement varies during the first few hours after removal of the band, the amount of the edema increasing and subsiding in waves, but never regaining its first extent, and gradually subsiding altogether. The accumulation of fluid stretches the walls of the capillaries and dilutes the toxins. Bacteria are unable to live in solutions of their own toxins, and this is one of the reasons why no bacteria are found alive in fresh edema. Toxins are diluted by the edema to such an extent that they are comparatively harmless for the organism. Another factor in the benefits of artificial edema is that absorption is prevented by the mechanical compression of the vessels by the accumulated fluid, and also by the fact that the parts of the body elsewhere are anemic, owing to the local congestion in the constricted limb. In addition to all these advantages of Bier's method of passive congestive hyperemia in the treatment of acute inflammation and wounds, it has the further point in its favor that the treatment of the lesion can be much simpler and gentler than by other technics. After incision of a phlegmon and application of the constricting bandage to the limb above, part of the accumulating serous secretions finds its way out through the wound. If all escaped this way it would be unnecessary to suspend the limb to promote the subsidence of the edema, but enough pours out through the wound to keep it rinsed with a natural irrigation and rendering tamponing or absorbent dressings superfluous. The frequent and painful manipulations necessary to prevent the union of the edges of the wound in severe infections are spared the patient treated with congestive hyperemia. This leaves the wound in peace, and this peace allows the tender structures to recuperate without injury. Under other conditions they suffer from the changing of dressings and absorbent applications, and are liable to fall a prey to necrosis. In conclusion, he remarks that the artificial edemization is only a single factor in the general effect of artificially induced congestive hyperemia. Bier calls the method "Stauungs-Therapie"; "Stauung" means the stowing away of a cargo in a ship, but it is applied to engorgement of any kind, and hence to passive congestion.

76. **Diagnosis of Hernia of the Diaphragm.**—Herz had occasion to observe a case of hernia of the diaphragm in which the descending colon, especially the splenic flexure, rose during inspiration and sank during expiration. He regards this symptom of paradoxical respiration as important for the differentiation of hernia from eventration of the diaphragm. The patient was a man of 30, always healthy, until two years previously he noticed that he was becoming corpulent, perspired more freely and suffered occasionally from dyspnea on exertion. One day he experienced great dyspnea while walking, and coughed considerably. These symptoms becoming more severe, he entered the hospital, complaining of a sense of oppression in the chest, especially at the lower third of the sternum. The percussion findings are illustrated. Herz differentiates the case as one of congenital hernia of the diaphragm with a large defect. The stomach is in its normal place. Lager found in 266 cases of hernia of the diaphragm in which several organs were involved that the stomach was in the hernia in 161 cases and the colon in 145, while in 53 cases in which only one organ was involved the stomach was implicated in 27, the colon in 13, the small intestine in 6 and the omentum only once.

78. **Cardiolysis in Mediastino-Pericarditis with Adhesion.**—Meyer-Westfeld states that besides Brauer's 3 cases and Beck's 3 there is only one other case on record in which an operation was undertaken for the relief of adhesive mediastino-pericarditis. He here describes an eighth case. The results of surgical intervention have invariably been good, accomplishing much more than could be anticipated from medical measures. In his case, the benefit was apparent in the complete subsidence of the symptoms of general stagnation, in the improvement of the symptoms of pseudo--cirrhosis of the liver, the stronger pulse and blood pressure, the vanishing of the relative insufficiency of the mitral valve, and, above all, in the return of an appreciable reserve force in the myocardium. This success is due only partially to the direct relief of the heart by the operation. This consisted in removal of the ribs covering the heart, resecting the fourth and fifth ribs from their attachment to the sternum to the region of the anterior axillary line. The heart thus released from its bonds rapidly recuperated, and soon threw off the disturbance manifested by the relative mitral insufficiency.

83. **Treatment of Acute Throat Affections with Bier's "Congestive Hyperemia."**—Hochhaus has treated 36 patients with diphtheria, 12 with ordinary sore throat and 7 with erysipelas by strapping a rubber band around the neck. Unmistakable benefit was derived in every case, he says, most pronounced in the diphtheria cases. Among the typical instances he reports is that of a child of 5 with pains in the neck and croupy cough for twenty-four hours. The tonsils were covered with false membrane. Antitoxin was injected and the strap applied to the neck. The false membrane was thrown off the third day, the child being dismissed completely well by the twelfth day. A young man with the same symptoms was treated with the congestive hyperemia alone and was dismissed cured in a week. In cases of erysipelas the process seemed to be arrested by the rubber band around the neck, and the patients could be dismissed in from three to five days.

84. **Utilization of Sugar Enemata in Diabetes.**—The sugar in an enema vanishes from the fluid in a short time, and it has been supposed that it is absorbed by the intestine. Bingel here presents evidence to show that the vanishing of the sugar can be explained by fermentation processes. Probably very little has been absorbed. In none of his tests could he trace the influence of sugar on the elimination of sugar or of nitrogen.

85. **Intubation in Asphyxia**—Kuhn protests against the application of the term asphyxia—which means arrest of the pulse—to arrest of the respiration. His method of intubation per os for artificial respiration, with introduction of air or oxygen under pressure above that of the atmosphere, has proved in his hands a wonderful technic for resuscitation in cases of apparent death. Dogs continue to breathe tranquilly and normally with both sides of the thorax open when the air is supplied to their lungs under plus pressure, but the moment the supply of air is cut off their lungs collapse and they apparently die. If the stopcock is turned and the air or oxygen is allowed to flow into the lungs once more, they expand at once, and if the heart has not ceased beating entirely the animal promptly revives. In the prevention of chloroform asphyxia, the pulse is an unreliable guide as, when it varies, the trouble is already too far advanced. As a rule, chloroform asphyxia is due to hindrance in the intake of air, and Kuhn thinks that the falling back of the tongue or of the jaw or other mechanical blunder is responsible for the large majority of such cases, and wonders that it does not occur oftener. The intake of air becomes insufficient and gradual carbonic acid gas intoxication results. The respiration is of much more importance than the pulse for the anesthetist. If absolutely free respiration is ensured, the dangers of anesthesia become reduced to the minimum at one stroke. This is ensured, he proclaims, by administering the anesthetic through a tube passing into the upper air passages and extending through the nose or mouth. He is convinced that intubation should be one of the indispensable preliminaries to anesthesia, or at least, that the tube should be at hand, ready for emergencies. It should also be used at once in all cases of arrest of respiration from mechanical or chemical causes. It is easily introduced in an asphyxiated person, and allows immediate artificial respiration with oxygen or not as indicated. In case of drowning, the pelvis should be raised and the head allowed to hang over backward. The tube is introduced through the mouth, and this allows aspirated fluids to escape, while it ensures free respiration as physical measures to induce artificial respiration are instituted. In case of chemical asphyxia, the tube allows the introduction of oxygen, the measure most urgently indicated. Venesection, infusion and massage of the heart are valuable adjuvants. In short, this method of intubation is the alpha and omega of prevention of asphyxia and of resuscitation in cases of apparent death. Kuhn's tube has a shoulder which prevents it from being bitten by the teeth and also prevents it from slipping in too far. See also 61 above.

87. **Prevention and Treatment of Gonorrhea.**—Sondermann applies aspiration to the urethra, followed by rinsing, and has found the combination remarkably effectual in preventing and curing infection. The cannula is perforated; it screws into the center of a rounding skeleton frame a little wider and longer. The top of the cannula is connected with a suction pump on the right and with a jar of water or some medicated fluid on the left. When the stopcock between the jar and the cannula is closed and the suction bulb squeezed, air is aspirated through the cannula out of the urethra and hyperemia is induced, while all the secretions are drawn away and the remotest crevices cleansed. By turning the stopcock, water flows into the urethra and is aspirated out by the pump, thus producing a constant outward flow. He gives an illustration of the simple combination of cannula, skeleton frame, the two jars and the rubber bulb. It has demonstrated its efficacy in prophylaxis of gonorrhea and also in aborting early cases, and it has even effected a cure in one chronic case in his experience.

96 *Zur Behandlung interstitieller Erkrankungen. Fälle von Tabes dorsalis und Myelitis chronica, mit Keratin behandelt. S. M. Zypkin. (Commenced in No. 32.)

88. **Protecting Action of Liver.**—In Rothberger's experiments on dogs, the animals remained in good health after the liver had been excluded from the circulation by tying off the portal vein. This occurred even when the animals were fed exclusively on meat. Experiences like these shake the foundations of the theory that the liver is the main agent in protecting the organism against toxins from the intestine. If the poisons generated in the intestine do not affect the general organism, he says, we have not the liver to thank for this as much as has been previously supposed. The walls of the intestine probably do not allow the poisons to pass through them.

90. **Radiometry.**—Freund and Oppenheim assert that the chemical appliances which measure the penetrating power of the Roentgen rays behave differently under varying temperatures. All tests to determine the chemical efficiency of the Roentgen rays, therefore, should be made at a standard room temperature, to enable the results to be compared. A temperature of 18 C. (65 F.) they suggest as a good standard. They further assert that biologic effect of the rays does not always parallel the findings of the radiochromometers.

91. **Dilatation of the Heart.**—Selig has been studying the effect of climbing stairs as a test of 40 patients with dilatation of the heart. Comparison of the findings showed that neither the blood pressure nor the pulse rate afforded such accurate information in regard to the functional capacity of the heart as the general aspect of fatigue. The appearance of *exhaustion is more conclusive than any symptom. He was surprised to find so many of his patients still capable of considerable* exertion without exhaustion, especially those who would be classed as cases of "congestion" dilatation. He believes that there must be another kind of dilatation besides that due to distension from defective contraction and that due to distension from over-supply of blood. The patients with dilatation who yet are capable of considerable effort without exhaustion must belong to this other category. He examined four football players after hard games and found that the blood pressure had dropped from 20 to 45 mm. mercury, and that the pulse had increased by 21 beats, while the apex beat had changed its location by 1.5 cm. in two of the players, and three had considerable albuminuria. None was cyanotic or exhausted, and yet Selig accepts the symptoms described as signs of incipient heart incapacity. Similar symptoms are observed in cases of valvular defect and arteriosclerosis after exertion, but in this case the patients all appear exhausted after exertion.

92. **Radium Treatment.**—Kahler gives illustrations of a case in which great improvement was obtained by combining exposures to radium with the usual measures. The accessible parts were treated with Roentgen rays, while the interior of the nose healed under the radium rays.

93. **Influence of Roentgen Rays on Course of Leukemia.**—Franke reports the details of 4 cases of leukemia treated by Roentgen exposures of the spleen alone. The results were strikingly beneficial, but not enduring. It is impossible to speak of a cure, but the results surpass anything ever realized before, so that Roentgen treatment should be instituted, he thinks, as a routine procedure in all cases of myeloid as well as lymphoid leukemia. He ascribes the improvement observed to the destruction by the rays of the leucocytogenetic tissue in the spleen. This destruction is followed by a reduction in the number of leucocytes in the blood and in the size of the spleen.

96. **Keratin in Treatment of Interstitial Affections.**—Zypkin became impressed with the possibilities of keratin in therapeutics *during the course of some experiments on mice in* regard to the synthesis of albumin bodies out of albuminoids. He used keratin and glutin principally in his experiments, and found that keratin seemed to prevent the proliferation of connective tissue which was observed in the course of his research in the animals not ingesting keratin. He describes various premises which led him to the conclusion that the animal organism has the faculty of synthetically binding keratin with glutin (the main constituent of connective tissue), and hence that keratin might prove effectual in the clinic in treatment of interstitial affections of various parenchymatous organs. He has applied this treatment in 4 cases, commencing with chronic affections of the central nervous system, as the slightest variation in the intensity of the pathologic anatomic process becomes clinically manifest in such cases much more perceptibly than in interstitial affections of other organs. The results answered his expectations. Three tabetics and one patient with chronic myelitis took ten or more keratin tablets a day for several months, and the improvement was actually striking in some and marked in all. *He explains the benefit as due to the binding of the glutin in* the connective tissue by the keratin, which permits the reabsorption of the new-formed connective tissue. The idea that keratin is not dissolved in time in the stomach is a mistaken one, he says. In conclusion, he remarks that many infectious diseases are accompanied by extensive parenchymatous changes in the internal organs, and yet the organs regain normal functional capacity afterward. This is due to the regeneration of the parenchymatous cells which proceeds unhindered. If the infectious agent has induced proliferation of the interstitial stroma in the organ, the infectious disease leaves behind it a stationary or progressive affection of the organ. The regeneration of the parenchymatous cells is prevented by compression from the proliferating interstitial tissue. It is especially in such cases that keratin may prove extremely useful, putting a stop to the proliferation of the connective tissue, improving certain symptoms and checking the further progress of the affection or curing it completely in time.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Practitioners' Visiting List (Heretofore known as the Medical News Visiting List) for 1906. A pocket-sized book, containing memoranda and data important for every physician, and ruled blanks for recording details of practice. The weekly, Monthly and 30-Patient Perpetual contain 32 pages of data and 160 pages of classified blanks. The 60-Patient Perpetual consists of 256 pages of blanks alone. Each in one wallet-shaped book, bound in flexible leather, with flap and pocket, pencil and rubber, and calendar for two years, $1.25. Lea Brothers & Co., Philadelphia, 1905.

A Quarterly Digest of Advances, Dis- in the Medical and Surgical Sciences.)., assisted by H. R. M. Landis, M.D., vol. IV. December, 1905. Diseases of the Digestive Tract and Allied Organs: Liver, Pancreas and Peritoneum—Anesthetics, Fractures, Dislocations, Amputations, Surgery of the Extremities and Orthopedics—Genito-Urinary Diseases—Diseases of the Kidneys—Practical Therapeutic Referendum. Paper. Pp. 367. Price, $6.00 per annum. Philadelphia: Lea Brothers & Co., 1905.

Baby Incubators. A Clinical Study of the Premature Infant, with Especial Reference to Incubator Institutions Conducted for Show Purposes, by J. Zahorsky, A.B., M.D. Reprinted from a series of Articles in the St. Louis Courier of Medicine, 1905. Cloth. Pp. 135. Price, $1.00 net. St. Louis, Mo.; Courier of Medicine Co., 1905.

Lectures on Autointoxication in Disease, or Self-Poisoning of the Individual, by Ch. Bouchard. Preface and New Chapters Added by T. Olive Second Edition. Cloth. Pp.342. Price, : F. A. Davis & Co., 1905.

Contribution L'Etude de la Funiculite Lympho-toxique dans les Pays Chauds. By Dr. R. Menocal. Professor de clinique chirurgicale à la Faculté de Médecine de la Havane. Paper. Pp. 28. Havana, Cuba: M. Ruiz y Ca., 18 rue Obispo, 1905.

Measurements of Twins. By E. L. Thorndike. Archives of Philosophy, Psychology and Scientific Methods. Edited by J. McK. Cattell and F. J. E. Woodbridge. No. 11. September, 1905. Paper. Pp. 64. New York: The Science Press.

Professional Education. United States Bureau of Education. Chapter from the Report of the Commissioner of Education for 1904. Advance Sheets. Chapter XXVII. Paper. Washington: Government Printing Office, 1905.

THE ELIMINATION OF CHLORIDS IN NEPHRITIS.

JOSEPH L. MILLER, M.D.

CHICAGO.

Widal and Javal[1] recently called attention to the inability of many nephritics to eliminate sodium chlorid in a normal manner. The salt retained in the tissues required a certain amount of water to maintain it in the proper molecular concentration, thus leading to edema; they offer this as the probable cause of dropsy in nephritis. This chlorid retention was found chiefly in acute and chronic parenchymatous nephritis, and especially in patients who were edematous. This retention was not found in the interstitial form, and we know that when edema develops in these cases it is usually of cardiac origin. They, furthermore, decided that the impermeability of the kidney to urea and salts did not necessarily go hand in hand, as in the terminal period of Bright's disease there may be marked retention of chlorids, but none of urea, phosphates or sulphates. They report a case of uremia, with daily elimination of 28 grams of urea, but only 0.39 grams of sodium chlorid. For this reason they consider the chlorid elimination as a better index of the functioning power of the kidney than the excretion of urea, and that the unfavorable progress of a case is associated with reduced chlorid elimination. With the chlorid retention there is increased elimination of sulphates and phosphates, and as the chlorids increase these salts diminish.

Only small amounts of sodium chlorid are essential for the animal economy. According to Bunge, a person on a mixed diet requires daily 1 to 2 grams; most people, however, consume 10 to 20 grams. The excess of chlorid is eliminated chiefly through the kidneys. The normal feces contain less than a gram daily, but as a result of diarrhea this may be increased to 4 or 5 grams. The skin eliminates on an average 1,000 c.c. of sweat containing 1 to 2 grams of sodium chlorid. The total daily elimination may, of course, be greatly increased by sweating, and some recent results point to increased sodium chlorid in the perspiration of patients with chlorid retention. In diseases associated with polyuria, as diabetes insipidus or interstitial nephritis, the sodium chlorid intake and excretion may be greatly increased, often reaching 25 to 30 grams daily.

The view is generally held that when a large excess of sodium chlorid is administered to a healthy person this rapidly appears in the urine, the maximum excretion occurring three to four hours after ingestion. Since the work of Widal, further study has been made[2] of the normal kidney and it has been found that the daily elimination of sodium chlorid suffers wide daily variation without any apparent cause. Koziczkowsky found on a fixed diet the daily elimination varied from 9.9 to 23.7 grams in one case and from 6.8 to 14.4 grams in another. He gave people with apparently healthy kidneys an additional 10 grams of sodium chlorid daily for three successive days, having previously estimated the daily output, and reports a chlorid retention of from 18 to 25 grams.

Patients with acute or chronic parenchymatous nephritis, when given, in addition to their usual diet, ten grams of salt, show only moderately increased chlorid in the urine. Except in very severe cases, the amount of urine is increased. When this increased ingestion of salt is continued for several days, the patients gain in weight due to the developing edema, the amount of albumin in the urine is increased, headache, nausea and stupor may develop; in short, a condition resembling uremia. Widal and Javal were able to make the edema appear and disappear at will by increasing or withdrawing the chlorids. The weight of one patient fluctuated from 56 to 60 kilos. The edema rapidly disappeared when the patient was placed either on a milk diet or on meat, bread and potatoes. The addition of ten grams of salt to either diet interfered with improvement. During the disappearance of the edema the daily amount of chlorids eliminated exceeded the intake 3.3 grams. The amount of albumin also decreased from 15 to 3.38 grams daily. When ten grams of salt was added to the milk daily, the urine decreased in amount and the daily retention of chlorids was 4.57 grams, the patient increasing 2.1 kilos in weight, the albumin increasing from 2.4 to 12.12 grams. The patient was then placed on a diet containing 400 grams of meat with bread and 2,500 c.c. of fluids. Within eleven days the weight decreased 3.7 kilos and the albumin had fallen to 0.72 grams daily, the edema reappearing when the salt was added to the diet. Numerous investigators have verified the above results. Koziczkowsky reports marked increase in the amount of chlorid in the various organs of patients with uremia. Courmont,[3] in three cases of acute or subacute nephritis, injected subcutaneously normal salt solution. After the second day the urine became scant, and two of the patients developed uremia. Nagelschmidt[4] produced an artificial nephritis in dogs and demonstrated chlorid retention with increase of salt in the blood. Castaigne[5] demonstrated that in animals with nephritis moderate amounts of sodium chlorid would double or triple the amount of albumin. He also reports that in patients with nephritis, without albuminuria, after the administration of salt, albumin appeared in the urine.

Wochft., 1902; 1904, Nos. 24, 25 and 26. Strauss: Zeitft. für klin. Med., vol. xlvii.

[3] Courmont: Lyon Médical, *ci*, 1903.

Kovesi has recently verified Widal's results and given some interesting additional information. Patients with chlorid retention increased in weight and became more edematous after ingestion of excessive amounts of salt, although the fluids taken during this time were not increased and the daily amount of urine not diminished. It must be that the elimination of water by other channels has been lessened. There was no increase in the liquids passed in the stool and there only remain the skin and lungs. He believes as a result of chlorid retention there is a lessening of the invisible perspiration. The amount of evaporation which takes place from the surface of the body is dependent not only on the moisture and temperature of the surrounding air, but also on the molecular concentration of the body fluids. The higher the osmotic pressure the less water is given up.

Soon after Widal's communication I began investigating the subject. The cases for study were obtained chiefly from the wards of Cook County and the Presbyterian hospitals. While no attempt was made to determine the exact intake of salt, the patients were kept on a fairly uniform diet during the period of investigation. In some cases this was milk only; in others, the light ward diet. The chlorids were estimated by the Volhard method. When possible, the patients were weighed daily. The sodium chlorid was administered at first in wafers, but, as this often produced nausea, it was later given in solution. The following method was pursued: The chlorids were estimated daily for nine consecutive days. The first three days the patient had merely the chlorids contained in his food; the following three days he received daily an additional ten grams; then the three following days merely the chlorids in his food.

In the accompanying table the total urine for each of the three-day periods is noted, the total chlorid in each period, the grams of chlorid retained at the end of the period when extra salt was given and the percentage of it in the urine during each period. During the second period ten grams of salt were administered daily, except in the cases indicated by an asterisk, where only five grams were given.

Two cases of acute nephritis were examined: one postdiphtheric with blood, epithelial and granular casts, but only a trace of albumin. There were marked uremic symptoms and moderate edema. The other was of six weeks' duration, the urine containing a large amount of albumin, many granular and epithelial casts, very slight edema. These patients were kept on an exclusive milk diet, consisting of 1,000 c.c. of milk and 250 c.c. of cream. One patient had a chlorid retention of 10.7, the other 24.8. In both there was a visible increase in the edema. One patient was weighed, gaining three pounds during the period, when extra chlorid was given, and losing it quickly after the salt was discontinued. In one case less urine was passed during the period of extra chlorid than in the preceding or following period. The percentage of chlorid in the urine was increased following the administration of the salt.

* Patients received five grams extra chlorid daily.
† Eliminate in excess of chlorids ingested.

Seven patients with chronic parenchymatous nephritis were examined. Six had more or less edema. The patient without edema had probably a secondary contracted kidney. The six patients with edema all had a chlorid retention varying from 8.9 to 29.24 grams during the three days of extra salt. The secondary contracted kidney eliminated 6.7 grams more chlorid than was ingested. In two cases the urine decreased in amount during the period of extra chlorid. Two patients showed marked increase in the edema and both complained of increased headache and stupor. One patient was taking Basham's mixture. A later test was made, with patient taking two grams of diuretin daily, with much better chlorid elimination. The patient with the least chlorid retention died; the one with the greatest retention left the hospital much improved. In two cases with marked edema the albumin was estimated by the Purdy method and the effect observed of potassium acetate, potassium neutral phosphate and theocin on the chlorids and albumin. The results were practically identical in the two cases. During the period of extra chlorid the albumin was decidedly increased. None of the remedies used increased the elimination of chlorid.

Two patients with uremia were examined. Both of these died before the tests were completed, so do not appear in the table. In both cases the urine was scant and the daily amount of chlorids less than two grams. Following the administration of salt, the urine was lessened, one case from 500 to 240 c.c., and scarcely any of the extra chlorid appeared. The edema was decidedly increased and the patient's condition worse.

---

[4] Nagelschmidt: Zeitft. für klin. Med., vol. 42.

[5] Castaigne and Rathery: Arch. de Méd. expér. et d'anat. path., vol. xv, 1903.

A patient with myocarditis, having fluid in the pleural, pericardial and abdominal cavities, showed marked increase in the daily urine following the administration of chlorids, and excreted 24 grams, or 8 grams daily more chlorid than was ingested. This patient showed actual improvement, which continued after the chlorid was discontinued. This might be considered an increased activity of the kidney due to the ingestion of large amounts of chlorid, analogous to the results of Claude, who found increased elimination of urea following the use of chlorids, or the results of Roque and Lemoine, who found increased activity of kidney to the phloridzin test after the use of common salt. In a single case of this sort, however, no conclusion should be drawn. While we are unable to disprove that excessive sodium chlorid stimulates kidney activity in certain cases, it appears doubtful, especially when we consider its action on the healthy kidney.

Four patients without apparent heart or kidney trouble were tested. All these showed a degree of chlorid retention almost, if not quite, equal to the nephritics. This difference might be mentioned in two, viz., the retained chlorid was eliminated within 48 hours after its discontinuance, while in nephritics it took place more gradually. In each case the administration of chlorids caused a marked increase in the amount of urine. Following the ingestion of the salt, the percentage of chlorids in the urine was increased, not, however, to such a degree as in the nephritics. No edema resulted. Assuming that the salt was absorbed from the intestinal tract, it must have remained in the tissues associated with sufficient water to maintain the proper dilution. In other words, these patients had an undemonstrable edema. The tissues of the nephritics were already water-logged so that any increase in edema was readily observed. In support of this view one of the patients was weighed daily and showed an increase in weight of 2¼ pounds following the administration of the chlorids. Novecourt and Vitry's experiments on nurslings is corroborative of this view. They administered daily for a period of seven days 0.25 to 1 gram of sodium chlorid, and found a greater increase in weight than for the same period on the same amount of food, but without the additional chlorid. They believe this is due to improved nutrition, but it is probably the result of water retention.

A summing up of the evidence would indicate that the chlorid retention in moderately severe nephritis is not greater than in the normal kidney. The terminal stages of nephritis, however, are characterized by very marked impermeability of the kidney to sodium chlorid. This difference, however, exists: in nephritics there is a visible increase in the edema, in the healthy individual there is no detectable edema. It is not necessarily true that a chlorid retention, after moderate excess of salt, exists in every healthy individual, but reports from various writers indicate that such is the rule.

Another phase of the question, and it would seem a much more important one, is the increase in the albuminuria and development of uremia symptoms following excessive chlorid ingestion. The view that the so-called uremia of nephritis is, in reality, a chloremia has little support. It appears that the increased cerebral edema is the more probable explanation. From a therapeutic standpoint, whatever the final decision regarding the impermeability of the nephritic kidney to chlorid, there is no doubt that excessive salt should be avoided, as it causes not only water retention, but by increasing the osmotic pressure of the blood lessens perspiration and the amount of water lost by respiration. Two grams of sodium chlorid daily are sufficient for the animal economy. Milk contains from 1.2 to 1.7 grams per liter; 100 grams of bread, on an average 1.3 grams; 1,000 grams of beef, 1.15 grams. Widal reports disappearance of edema and general improvement on a diet consisting of meat, 400 grams; potatoes, 1,000 grams; sugar, 100 grams; butter (unsalted), 80 grams; fluids, 2,500 c.c. This diet contains only 1.5 grams of chlorid. Especially to be avoided are the soups and broths, as they contain large amounts of salt, the broths at the Cook County Hospital containing 11.3 grams per liter, and many patients drink 500 c.c. of this daily. The use of subcutaneous injections of salt is contraindicated, as it may favor the development of uremia. I do not believe that the degree of chlorid retention is necessarily an index of the extent of kidney incompetency. Two cases of nephritis with a mild degree of retention died, while the patient with the highest degree of retention left the hospital much improved.

CONCLUSIONS.

In patients with moderately severe nephritis associated with edema, the ingestion of large amounts of sodium chlorid is followed by a chlorid retention. The patient gains in weight, the edema becomes more marked, the albuminuria increases and symptoms may develop resembling uremia.

In patients with severe nephritis, and especially those with uremia, chlorid retention is very marked, as scarcely any of the extra chlorids administered are eliminated.

In individuals with apparently healthy kidneys, following the ingestion of sodium chlorid, there is a chlorid retention equal to that of mild nephritis. The individual gains in weight, but there is no visible edema, no albuminuria and no uremic symptoms appear.

THE PHARMACOLOGY OF DIETHYLOXYACETYL UREA.*

E. M. HOUGHTON, M.D.
DETROIT, MICH.

Some weeks ago my attention was called to a new group of chemical bodies belonging to the methane series. According to A. H. C. Heitmann and Erik Clemmensen, the discoverers, they are condensation products of urea and the various oxyacetic acids. A consideration of the chemical structure of these compounds led to the belief that all would possess considerable hypnotic power, but the ethyl compound was thought to be the more promising for therapeutic purposes. The originators accordingly prepared and placed at my disposal sufficient quantities of the ethyl derivative in its pure state, and a little later its sodium salt, to undertake a series of animal experiments to demonstrate its pharmacologic properties.

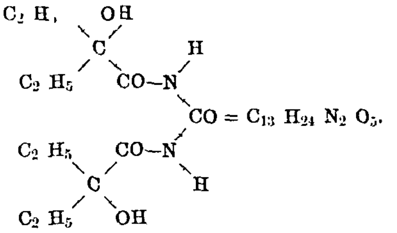
Perhaps the most desirable chemical name that can be given to the compound, as indicating its structure, is the one mentioned in the title of the paper, diethyloxyacetyl urea. The chemical formula is given by

---

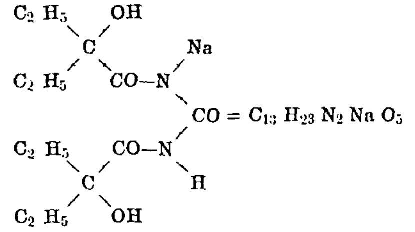
* Read before the central branch of the Am. Physiological Society, March 29, 1905, at Chicago.

Clemmensen and Heitmann as $C_{13}H_{24}N_2O_5$, with the following structural formula:

1. Diethyloxyacetyl urea[1]:



2. The sodium salt of diethyloxyacetyl urea:



A great deal of attention has been given by pharmacologists to the relation between chemical structure and physiologic action, with the result that one may predict beforehand in many instances, with a greater or less degree of certainty, the effects that will be produced on animals by the administration of chemical substances with definite structural formulæ. Schmiedeberg, considering the formula of urea $CO\genfrac{}{}{0pt}{}{\diagup NH_2}{\diagdown NH_2}$, concluded that by replacing one of the amidogen groups with an ethyl alcohol radical the resulting compound $CO\genfrac{}{}{0pt}{}{\diagup NH_2}{\diagdown C_2HO_5}$ would possess the desired hypnotic action.

The ethyl group would depress the cerebral centers, while the amidogen group, by its stimulating action, would correct a too pronounced depression of the respiratory and other important medullary centers. This compound Schmiedeberg called urethane. Tests of it on rabbits showed it to be almost an ideal hypnotic, but, when administered to human beings, it was found to require very large doses, and even then was not certain in its effects. Apparently, the stimulating effect of the amidogen group was too great or the depressant effect of the alcohol group too slight for the changed relations between the size of the cerebral substance and that of the lower portions of the central nervous system of the human being as compared with the rabbit. Computing the amount of C_2H_5 and the nitrogen in urethane, we find that they constitute 31 per cent. and 15 per cent., respectively, of its molecular weight. Emil Fischer and J. v. Mering[2] called attention to urea compounds of the fatty-acid series, and proposed diethylmalonyl urea as a hypnotic. This compound contains 31.5 per cent. C_2H_5 and 12.5 per cent. nitrogen, very nearly the same percentages as are found in urethane. Computing the percentage of C_2H_5 (the ethyl radicals) and nitrogen in the above formula for the diethyloxyacetyl urea, we find it amounts to 40 per cent. and 9.6 per cent., respectively, there being a considerable increase in the percentage of the ethyl radicals and a decrease in the percentage of the nitrogen as compared with urethane. Hence the supposition that it would be more active as an hypnotic than urethane, possibly containing just the right percentage of the depressing alcohol radicals and the stimulating nitrogen compounds to produce as desirable hypnotic action for higher animals and human beings with their relatively large amount of cerebral substance as urethane for rabbits with their comparatively small amount of cerebral substance. While predictions of this kind have often been wofully misleading, further experiments and clinical trials show that the reasoning in the above comparison is worthy of serious consideration.

The diethyloxyacetyl urea is a clear, transparent, slightly soluble, oily liquid, sp. gr. 1.1107, with a peculiar characteristic etherial odor and taste. It is soluble in about twenty parts of water, and is quite soluble in most of the organic solvents, e. g., in alcohol, ether, chloroform, etc. The sodium salt forms beautiful flakelike crystals, which are very soluble in water and have a mild peculiar taste. This latter compound contains 11 per cent. of sodium, and on account of its great solubility, promises to be of more importance than the mother compound. Experiments show that both act in essentially the same manner, but the time has been too short and the supply of the drug too limited to fully complete the investigations. Consequently, this communication should be regarded as a preliminary report to be followed later by a more comprehensive paper dealing with the whole group of urids of the group of oxyacetic compounds.

As Clemmensen and Heitmann are now preparing an exhaustive chemical paper on the subject, I shall not take up the method of preparing these bodies or discuss their chemical relations, but will simply state that they are condensation products of urea and the various oxyacetic acids.

ANTISEPTIC AND GERMICIDAL PROPERTIES.

A series of culture tests, employing *B. pyocyaneus* as a test organism, showed that the drug and its sodium salt possess very slight antiseptic and germicidal properties.

TOXICITY.

Several series of experiments using frogs and guinea-pigs showed that the compound is but very slightly toxic. The minimum fatal dose for frogs, when the substance was injected into the abdominal lymph sac in physiologic salt solution, was 0.005 to 0.006 per gram body weight (Table 1.); for guinea-pigs when administered subcutaneously, 0.8 per kilogram body weight; and for guinea-pig per stomach, 0.8 per kilogram body weight (Table 2). The series of experiments were repeated several times. The tables are typical of the detailed results obtained when the substance was administered in the several ways mentioned.

TABLE 1.—Sodium Salt of Diethyloxyacetyl Urea. Toxic Dose for Frogs when Injected into Abdominal Lymph Sac.

Number.	Weight.	Dose per Gm.	Result.
1	27	.004	Lived.
2	35	.005	Lived.
3	17	.005	Lived.
4	37	.005	Lived.
5	31	.005	Died.
6	25.5	.006	Died.
7	18.5	.006	Died.
8	19	.006	Died.
9	23	.006	Alive.
10	34.5	.007	Died.
11	28.5	.008	Died.
12	37	.009	Died.
13	34	.010	Died.

Minimum fatal dose per gram body weight .006.

In a similar manner the toxic dose for the mother compound was found to be .005 per gram body weight.

---

[1] I shall hereafter call this "the drug," as we have no short name for it. Since the paper was written the name Hypnotal has been provisionally adopted.

[2] Die Therapie der gegenwart, March, 1903.

Frogs.—A series of frogs were injected with small quantities of the drug in the abdominal lymph sac. Very promptly the hypnotic action of the drug was shown, the animals becoming very sluggish, the head falling to the bottom of the cage, but they could be aroused by pinching the toes, when reasonable quantities of the drug had been employed.

Gold Fish.—Small gold fish were immersed in solutions of the drug in well-aërated river water, and it was found that their movements became more and more sluggish, until at the end of about fifteen minutes they would float to the surface. In most instances the fish did not show a stage of excitement, as so often occurs when chloral and similar chemicals are used. After a time all respiratory movements of the gills ceased, but, if the fish were placed in fresh water before the entire cessation of respiratory movements, complete recovery occurred in an hour or two. Recovery was hastened if the fish were placed for a few minutes in a dilute salt solution, and then in the aërated river water.

TABLE 2.—Diethyloxyacetyl Urea. Toxicity for Guinea-Pigs when Administered per Stomach.

Number.	Weight. Average.	Dose per Kilo.	Per Cent. Sol.	Result.
1.	500 gms.	0.5	10	Lived.
2.	500 "	0.6	10	Lived.
3.	500 "	0.6	10	Lived.
4.	500 "	0.7	10	Lived.
5.	500 "	0.7	10	Lived.
6.	500 "	0.7	10	Lived.
7.	500 "	0.8	10	Died.
8.	500 "	0.8	10	Died.
9.	500 "	0.9	10	Died.
10.	500 "	1	10	Died.
11.	500 "	1.2	10	Died.

Minimum fatal dose per kilo 0.8 grams.
The toxicity was found to be substantially the same when the drug was given subcutaneously.

Rats.—A number of gray rats were caught in the stables, and, as they were very wild, were considered desirable subjects for experimentation. Accordingly, a series of them were injected subcutaneously with various doses of the drug, and within a very short time the animals lost their ferociousness, and were soon sleeping quietly in the bottom of the cage. Here again it was possible to arouse them without any great difficulty, but as soon as they were allowed to remain quiet they quickly went to sleep again. The following day they were found as untamable as in their natural condition. They were then destroyed by the use of illuminating gas, and post-mortem examination showed but little irritation at the point of injection.

Guinea-Pigs.—A large number of these animals, weighing from 480 to 500 gms., received the drug subcutaneously and per stomach. They were found to be less susceptible to the hypnotic influence of the drug than rats, dogs or frogs. The animals occasionally, when large doses were given, showed a period of excitement similar to that produced by chloroform, ether, etc., and only became unconscious when very large doses were administered. In a number of instances the animals were destroyed with illuminating gas, and evidence of inflammation searched for at the point of injection. Here, again, as in the case of the rats, very slight reaction had occurred.

GENERAL ACTION ON TEMPERATURE, RESPIRATION AND PULSE.

A series of twenty dogs of different weight and breed were used for the purpose of determining the general action of the drug when administered to the animals in various ways: per stomach, per rectum, subcutaneously, intraperitoneally and intravenously. All the experiments showed conclusively that the compound possesses decided hypnotic properties, that in reasonable doses it did not have much influence on temperature, respiration and pulse. Table 3 is typical of the results obtained, indicating in detail the action of the drug on one of these animals. One characteristic of the action of the drug, which was always particularly notable, was the ease with which the animals could be awakened even when very deeply asleep, and, when so aroused, they readily partook of food and drink and the excretory

7	11:14 "	. . . .	. . . .	. . . .	. . . .	Changed drum.
8	11:47 "	122	10	33	5	25 c.c. sodium.
9	11:48 "	. . . .	. . . .	29	. . . .	
10	11:56 "	. . . .	. . . .	29	. . . .	Stopped drum.

organs were active. In some instances, after very large doses, the animals showed some tendency to dizziness, but this was much less pronounced than is often noticed with drugs of this class. Very large doses produced complete anesthesia, and, if repeated from day to day, the animals would ultimately die of exhaustion, but if the drug was discontinued within a reasonable length of time, even though the animal was completely anesthetized, recovery was complete.

Dogs.—A large number of experiments were made on dogs anesthetized with chloretone and morphin, a method that I have used for several years for rendering animals unconscious when employed for making blood pressure and other experiments.

Blood-pressure tracings were made from the carotid artery by means of a mercury manometer, and the myocardiograph records were taken from the right ventricle by means of Roy and Adami's myocardiograph, the animals being supplied with artificial respiration. Experiment 15 shows the results obtained in one typical experiment.

SUMMARY AND CONCLUSIONS.

1. Diethyloxyacetyl urea is a clear, transparent, slightly soluble, oily liquid, sp. gr. 1.1117, with characteristic etherial odor and taste. Chemical formula $C_{13}H_{24}N_2O_5$.
2. The sodium salt forms flaky, very soluble crystals, having a mild etherial taste. Chemical formula $C_{13}H_{23}N_2NaO_5$.
3. Consideration of its chemical structure warrants the belief that the depressing ethyl group, 40 per cent., and stimulating nitrogen, 9.6 per cent., are in the right proportion to produce a safe and efficient hypnotic.
4. Experiments on warm and cold-blooded animals show that diethyloxyacetyl urea is a relatively non-toxic chemical compound.
5. Prompt hypnotic action is produced in warm and cold-blooded animals when the drug is exhibited in any one of the usual methods of administration.
6. Complete anesthesia is produced by large doses, from which recovery is complete.
7. Pulse rate, blood pressure, heart action and respiration are but slightly, if at all, influenced by reasonably sized doses.
8. While the laboratory results indicate that diethyloxyaceteyl urea will be of practical value, it remains to be demonstrated by clinical experiments whether it will prove to be a desirable hypnotic for human beings.

INVERSION OF THE UTERUS,

WITH REPORT OF TWO CASES REPLACED BY LAPAROTOMY.*

L. V. FRIEDMAN, M.D.
Assistant in Obstetrics, Harvard University.
BOSTON.

Inversion of the uterus is that form of displacement in which the uterus is turned inside out. For some hundreds of years[1] it has been the custom to describe two forms—partial and incomplete. In the partial form the fundus, though indented, does not pass through the os externum; in the complete form the fundus has been expressed through the os, so that the entire uterine cavity is obliterated. As both the method of diagnosis and the treatment vary with the degree of inversion, I would suggest that the first be called "initial," the term "partial" being reserved for those cases in which, although the fundus has passed through the os externum into the vagina, the inversion has not proceeded far enough to obliterate the uterine cavity. This is in accord with the German terminology.[2]

From a study of reported cases and from my own experience in the two cases here reported, I am led to believe that this is by far the most common form, and I shall discuss it more fully in considering diagnosis.

ETIOLOGY.

Any consideration of etiology must be preceded by a word as to the pathologic findings. Authoritative pathologic examinations are necessarily rare, since in recent years it has usually been possible to replace the uterus instead of removing it. Peterson[3] examined the tissues cut from the sides of his anterior incision; these showed an increase of connective tissue in the muscularis with sclerotic changes in the blood vessels. In the meshes of the fibrin deposit on the mucosa were found cell-débris and leucocytes. It has been generally assumed as an hypothesis that inversion occurs only where there has been paralysis of the uterine musculature at some point, which, being inactive, is forced in by the contractions of the surrounding muscular tissue.[4] Such paralysis is most apt to occur at the placental site, and we have consequently a large proportion of puerperal cases.

The statistics of Crosse,[5] based on 400 collected cases, are accepted to-day, and show about 88 per cent. puerperal; 12 per cent. due to fibroids and isolated instances of other causes. Given the pathologic paralysis, almost any muscular exertion, such as coughing or sneezing, may prove an exciting cause. The commonly accepted causes are: Traction on the adherent placenta, precipitate delivery, short umbilical cord, traction by tumors. The remarkable cases attested by Baudelocque, Parker and others of inversion of the virgin uterus in the absence of tumor, are probably to be explained as following an unrecognized dilatation by hematometra. In the great majority of cases the inversion begins either centrally in the fundus, or in one cornu, but another form has been established which is due to a progressive eversion which begins at the cervix. The condition is probably much more frequent than is indicated by the oft-published statistics of Denham,[6] who found but one acute inversion in 100,000 births in Dublin, and C. v. Braun, who did not meet with an instance in 250,000 births in Vienna.

Inversions are considered as acute or chronic. It is impossible to set a definite time limit for the acute stage, but it is probably less than twenty-four hours, and the change in the uterine tissues which constitutes the essential feature of the chronic condition may take place within a few hours of the inversion.

Acute inversion is usually accompanied by sharp pain, shock, hemorrhage and collapse. Yet any one or all of these symptoms may be missing. This is particularly true of pain, as inversion is apt to occur while the patient is still unconscious from the anesthetic given at the close of normal labor or for operative procedures.

---

* I wish to acknowledge my deep obligation to Drs. Charles M. Green and Franklin S. Newell, my seniors on the gynecologic staff at the Boston City Hospital, for the opportunity of operating on the cases here reported and particularly for their skilled assistance (from the vaginal side), without which my procedure would have been futile.

[1] Soranus of Ephesus (A. D. 110) states that "inversio uteri" may follow the careless removal of adherent placenta. Ermerins. Ephesii, Liber de Muliebribus Affectionibus, 1869, Ch. xxii.

Sc., 1866, vol. xlii, p. 181.

Chronic inversion also may have few or no symptoms, or there may be occasional hemorrhage with consequent anemia, disorders of urinary apparatus, difficult defecation or constipation and discomfort in walking or standing. Complications may occur in acute inversion, but are more often met with in old chronic cases. Thus in an acute case the inversion may be the result of the expression of a large sessile intra-uterine tumor, in which case it is difficult to establish the upper limit of the tumor, or the beginning of the uterine tissue.[7] The complicating tumor may be a subperitoneal myoma, which is mistaken for the fundus in normal situation.[8]

In chronic cases, adhesions may form between the extruded endometrium and the cervix or vagina. There may be adhesions between the peritoneal coats abnormally in contact in the peritoneal crater or between the round ligaments, Fallopian tubes and the peritoneal lining of this crater. The contraction of the cervical ring may be sufficiently tight to cut off the circulation and cause gangrene of the uterus, and of the round ligaments and Fallopian tubes in so far as they lie below the cervix in the crater. Finally, where the blood supply is merely diminished we may have atrophy of the inverted fundus, the endometrium of which has been converted into a tissue resembling skin through its constant friction with the vaginal walls or between the thighs.

In spite of the fact that immediate reposition is usually easy and safe, the prognosis in acute inversion probably will remain always a grave one. Death may occur in a comparatively short interval as a result of extreme shock, or of sudden overwhelming hemorrhage. In the remarkable case reported by Anderodias,[9] he saw the patient less than two hours after the inversion occurred, and though reposition by taxis was comparatively easy, the patient collapsed and died instantly after the maneuvre. Crosse gives a mortality of 73 per cent. in 109 cases; Winckel's more modern statistics show a mortality of 22 per cent. in 54 cases.

Considering unrecognized instances, the mortality is probably higher than the last-named percentage. If the patient lives through the acute stage, her life is endangered by the possibility of acute infection of the endometrium, and later by periodic and irregular hemorrhage and by the grave operative risks incurred in seeking relief for the condition. A certain number of spontaneous repositions are recorded. Thomas,[10] in a classical article on the subject, quotes twelve such cases, and the following anecdote: "There is nothing easier than the rejection of the testimony of others, and the discrediting of deductions which we ourselves have not drawn. When De La Barre presented his case of spontaneous reposition to the Academy of Surgery, Baudelocque was appointed a committee to examine into it and reported that it was 'totally false.' Some years afterwards he met with a very similar case, and yielded to the evidence of his own senses a credence which he had presumptuously denied to the assertions of another."

DIAGNOSIS.

The diagnosis of inversion is usually difficult. Apart from numerous instances where the mass has been excised or morcellated as a polyp without considering the possibility of inversion, many eminent surgeons have erred after the most careful attempts at diagnosis, and in no condition is an error in diagnosis fraught with more danger to the patient. The possibility of inversion of the uterus must be considered whenever a uterine, cervical or vaginal tumor is detected by the physician. Even where the microscopic examination of snippings reveals a fibroma or sarcoma, the possibility of a complicating inversion must be borne in mind.

Velpeau[11] said in regard to this diagnosis: "In some cases doubt is the only rational opinion." Gooch,[12] in his essay, writes: "When partially inverted, the tumor in the smoothness of its surface, the roundness of its body, the narrowness of its neck, and its being encircled by the orifice of the uterus, sometimes exactly resembles polypus of the fundus."

The differential diagnosis lies between inversion, uterine tumor (polyp, fibroid or sarcoma) and procidentia. The last named should be ruled out by a careful examination, but a tumor may deceive in various ways. The orifices of the tubes are by no means always obvious. Where the fundus remains in the vagina they can not be detected, and even where the fundus is outside of the vulva these minute orifices, buried in the thickened endometrium, must be demonstrated with difficulty. The sound is not infallible, as a fibroid polyp may be adherent throughout the cervical circumference, and thus prevent the entrance of the sound. In partial inversion, even a fortnight after labor, the sub-involuted uterine cavity may admit the sound to the normal depth, though its fundus has passed through the os. During a protracted examination the uterus is apt to remain in a state of tonic contraction, when it is so hard as to simulate, not merely the body of a fibroid, but also its pedicle. The detection of contractions in the mass and its relaxation under full anesthesia may prove a valuable aid to diagnosis. The differentiation of the subjective sensations of the patient when the mass is touched is certainly of doubtful value. Through a very thin and much-relaxed abdominal wall under full anesthesia it may be possible to detect the depression or crater where the fundus should be (this was true in one of my cases, but not in the other), but where the ring is tightly contracted, filled with both round ligaments and both Fallopian tubes, and capped by the ovaries, there is no depression to be felt. When not in a state of contraction, the inverted uterus, if grasped and held by the examining hand, becomes distinctly diminished in size, and considerable bloody serum is expressed from the very edematous endometrium. In neither of my cases was there sufficient bleeding, as a result of examination and taxis, to be worthy of note.

As inversion may occur after labor without pain, hemorrhage, or pronounced shock, the favorable minutes for replacing may have elapsed before either patient or attendant is aware of the serious complication. Consequently, the obstetrician must always assure himself immediately after the delivery of the placenta that the spheroid of the fundus is convex, and this, fortunately, it is usually easy to do, because of the marked relaxation of the abdominal walls. Where the patient has complained of sharp pain during a forcible expression of the placenta, or where this event is followed by hemorrhage, if the uterus can not be outlined by abdominal palpation, a careful vaginal examination is indicated. It hardly seems necessary to reiterate the prophylactic proverb "do not pull on the cord." Further prophylactic measures are the avoidance of undue force in Credé's method, and the complete abstention from pressure on the fundus while it is relaxed. However, the possibility of spontaneous inversion some hours after the delivery of the placenta has been well established.

METHODS OF TREATMENT.

Peterson[3] gives a perfect summary of the methods of treatment,[13] and I shall detail in regard to treatment only sufficient to make clear my contention for the abdominal route.

In acute inversion, an immediate attempt to replace should be made, if the patient's condition permits. But if there be extreme shock, provided the hemorrhage can be controlled, it is advisable to defer all manipulation. The method of replacing by taxis is simple, but difficult to execute. The theory that the placenta, if still attached to the fundus, should be left as found until after reposition to avoid further hemorrhage, has many objections. Inversion is most apt to occur where the placenta is adherent, and such a placenta can be separated much easier before than after reposition. Further, the placenta increases the bulk of the mass, which is to be returned through the constricted os. After years of discussion there is to-day practical unanimity that the part of the uterus last inverted should be returned first. The patient should be given full anesthesia. The bladder and the rectum having been emptied, one hand passed into the vagina grasps the inverted fundus and compresses it so as to express serum and reduce its bulk. The fingers of the vaginal hand attempt alternately to dilate the cervical ring and to push through it that part of the uterus which lies just below the ring in the vagina. Meanwhile with the other hand, counterpressure is made through the abdominal wall, and where the wall is thin and thoroughly relaxed the fingers may enter the ring from above and aid in its dilatation. In view of the additional shock entailed by prolonged and forcible taxis, and the success of operative procedures, both the force and duration of taxis should be limited sharply. Rupture of the vagina and injury to adjacent organs is not a rare sequel of forcible taxis. When reposition has been effected, the uterus should be washed out with hot saline solution, and if it does not contract firmly, it is to be packed.

In chronic inversion, taxis should always be given a trial, particularly as it will usually demonstrate whether it seems advisable to attempt to replace the uterus intact by the abdominal method, or whether vaginal section of both cervix and uterus are indicated, because of the firmness of the ring and the solidity of the fundus. If taxis fail, the numerous older methods may well be passed by and either the vaginal or abdominal section may be chosen. These older methods were not without grave risks. They attempted reposition by taxis with the whole hand in the rectum or with the fingers in the bladder, by the use of prolonged pressure by means of air or water-bags or spiral springs. Where the conservative operative measures fail, recourse to hysterectomy or amputation is indicated.

Peterson divides the vaginal operations into four classes according to whether the incision is partial, from cervix to fundus, or complete, through the cervix to the fundus, and according to whether the incision is made in the anterior or posterior wall of the uterus.

The ideal vaginal method (known as Spinelli's operation), was used by Peterson. It is the complete anterior colpo-hysterotomy. The vesico-uterine peritoneal pouch is opened, the cervix is stretched from side to side, and an incision is then made through the cervix and uterus to within one-third inch of the fundus. The uterus is then easily reinverted, and the incision closed as in Cesarean section.

There are certain objections to the vaginal route. The tubes and round ligaments are exposed to vaginal contamination and then immediately turned free into the abdomen. As both tubes, round ligaments and sometimes a loop of bowel are packed tightly into the crater, there is the risk of injury to these organs in making the incision. If the vaginal incision is made posteriorly, there is apt to result an adherent retroversion; if made anteriorly, we have the undesirable vaginal fixation. Finally, there is the possibility of a rupture of the uterine scar in a subsequent pregnancy.

THE ABDOMINAL ROUTE.

In 1869, T. G. Thomas published an account of a case successfully treated by abdominal section and intra-abdominal dilatation of the cervical ring. This case was a chronic inversion of two years' duration. Subsequently he reported a second case of eight months' duration, in which reposition was equally successful, but the patient died of peritonitis some days later. Peterson collected fifteen cases of inversion treated by the abdominal route. Of these, eight were successful and seven complete failures. (It does not seem just to consider Thomas' second case a failure, although it resulted fatally.) Of the eight successes, three promised failure until the ring was incised. I have not been able to find any record of a similar operation since the publication of Peterson's paper. Counting Thomas' second case as a mechanical success, and adding my two cases, we have a successful percentage of 73 per cent. This compares poorly with the record of Spinelli's operation, performed six times with six successes. However, if due allowance is made for the small numbers on which these statistics are based, and for the constant recent improvement in abdominal surgery, I believe that the abdominal operation will be developed so that its record will be superior to the vaginal. I certainly do not advise the abdominal operation in all cases of inversion. In this, as in all other surgical diseases, the operation must be chosen after due consideration of the individual case.

Details of Operation.—The bladder and rectum are emptied. The vagina and uterus are thoroughly cleansed by prolonged washing with warm saline solution. After the usual preparation of the abdomen, it is opened by a median incision, the patient being in the high Trendelenberg position, and so draped with the sterile sheets as to permit access to the vagina. Immediately the bowels are pushed upward and "walled off" by a plentiful supply of gauze. If properly done this decreases greatly the shock and danger of the operation, as it limits sharply the extent of peritoneal exposure and trauma. If possible, the ring is dilated with the fingers, but if the constriction is so tight as to prevent this procedure, the ring is dilated first with a steel dilator of the Wathen or Goodell type, then with Reynold's dilator, which is peculiarly serviceable. In inserting the steel dilator and in dilating, care must be taken to avoid pressure on the tubes and round ligaments. Only moderate force should be used, and this must be regulated by the hand and not by any mechanical device on the dilator. In a few minutes it will be possible to partly withdraw the round ligaments and tubes, though no force is to be employed in order to accomplish this, and no attempt should be made to reinvert the uterus by traction on the ligaments or tubes. An assistant places the hand in the vagina and begins to carry up that part of the uterus which descended last; as this rises it is caught and held with volsellum forceps. Thereon the process of dilatation, reinverting and holding are repeated until the operation is complete. No attempt at traction on the volsellum forceps is permissible, as it will result merely in lacerating the peritoneal covering of the uterus itself. Progress at first is very slow, but after a certain point is reached the fundus slides through the ring into position. Meanwhile the abdominal assistant has offered counterpressure against the ring. When the uterus has been replaced, it may be suspended, but as involution proceeds rapidly during the hours following reposition, it is better merely to support the fundus for a few minutes, during which the uterus will begin to contract and retract, and the tubes, if not too long or too severely constricted, will regain practically their normal appearance. The gauze is removed and the abdomen closed in tiers. The table is then lowered, the foot-piece dropped, and two nurses hold the patient's legs in the lithotomy position, while a hot intrauterine douche is given by the vaginal assistant who has not withdrawn his hand until the operator has felt assured that the uterus would remain in place. The operation does not require more than forty-five minutes from beginning to end. As the work of the vaginal assistant requires more skill and is more important than the abdominal maneuvres, the assistant should be chosen accordingly.

---

[13] Excellent bibliographies are given in the articles of Peterson and v. Winckel, already referred to.

If this operation can be perfected so as to insure invariable mechanical success, there can be no doubt that it will be an ideal procedure for reposition of the inverted uterus, which is thus restored intact to its original position without violating the integrity of its peritoneal cover. Further, it permits an inspection of the tubes, which in an old case may require resection.

The two cases here reported were treated within thirteen months on the Gynecologic Service of the Boston City Hospital.

CASE 1.—Mrs. E. R., aged 29. American by birth; i-para. Family and past history negative. Five days before I saw her patient had given birth to a living baby after a rather long and difficult labor. The placenta was expelled naturally without unusual pain or other symptoms. Two hours later she had a moderate hemorrhage which was repeated at intervals until vaginal examination disclosed a tumor, when she was sent to the hospital. At entrance temperature 101.5, pulse 114. Pulse regular, good volume and tension. Abdomen normally tympanitic and not tender. What appeared to be a fibroid the size of a large pear protruded from the vulva and on vaginal examination was found to pass through the cervix. Leucocytosis of 17,800.

The patient was kept under observation for a few days until the sloughing perineum could be rendered clean. Then under ether, a final examination was made, which revealed the error in diagnosis. The sound halted when an attempt was made to enter the os at the side of the mass, and careful abdominal palpation revealed the crater. Attempts to reduce the inversion by taxis failed and after forty-five minutes of careful manipulation the patient was put to bed and prepared for laparotomy on the following day.

Operation.—Patient in high Trendelenburg position. The sterile sheets draped over each thigh separately so as to permit access to the vagina. The abdomen having been opened by a median incision, the bowel was carefully packed towards the diaphragm with gauze strips. The uterus presented the striking picture of complete inversion. Both tubes and both round ligaments were within the inverted cavity, the tubes were deeply injected, purple, and thrice the normal size. The ovaries also wine-colored and tense, rested on the brim of the cavity. The ring was firm and could not be dilated with the fingers. The ring was then carefully dilated with Reynolds' dilators, which were inserted so as to avoid injury to the tubes. The assistant's hand in the vagina then began the process of reposition. The anterior wall was raised, and as it came up it was caught and held with volsellum forceps. As each centimeter was gained, another pair of forceps was applied. The traction from above was reduced to a minimum. As soon as possible the tubes were delivered. This gave more room, and after repeating the dilatation with the Reynolds dilators, the fundus slipped through the ring. The congestion of tubes and ovaries quickly disappeared. The uterus contracted and showed no tendency to invert. However, as the fundus tended to sink back into the fossa of Douglas, it was lightly suspended. When the volsellum forceps were first applied, some traction was made which caused them to tear out and leave a small nick in the peritoneal coat of the uterus. This was readily closed with one stitch of fine catgut.

The operation consumed less than half an hour. It was attended by very moderate shock. At the close of the operation a copious hot intrauterine irrigation of salt solution was given. Six hours after operation the pulse was 104, temperature 101.4. The subsequent convalescence was uneventful.

CASE 2.—Mrs. M. H., aged 37. Irish by birth; iii-para. Patient had an instrumental delivery at her first labor in 1901. Her second labor (1903) had been normal. Her third labor was terminated after twenty-one hours by a high forceps operation. Shortly after delivery the placenta was expelled, without aid, and was found still attached to the fundus, which had come down with it. There was little pain, only slight shock, and no hemorrhage. Attempts to replace by taxis having failed, the patient was sent to the hospital, where I saw her twelve hours after delivery.

Patient did not look anemic, but was pallid. The expression was anxious, the facies typical of shock. The pulse was small and rapid (130), the temperature 100. The abdomen was normally tympanitic, not distended, not tender. Protruding from the dilated os was a round, hard mass, the size of a fist. The examining fingers passed completely around this mass, which appeared to be attached by a thick twisted pedicle which passed through a tightly constricted internal os. Although no depression of the fundus could be felt, a provisional diagnosis of inversion was made, and, under ether, a short attempt was made to replace by taxis. As this did not succeed, even in part, and as the mass remained hard, I decided that I was dealing with a fibroid. There was no hemorrhage, but the patient's condition was such that all further procedure was deferred until treatment for shock had been instituted.

This was at night. The following morning the patient was greatly improved; under ether a slight depression could be felt in the fundus, and the vaginal mass soft, so that the diagnosis was obvious. Taxis having again failed, the patient was prepared and the abdomen opened.

Operation.—Median incision. The conditions were similar to those described in Case 1. The ring was readily dilated with the fingers, so as to admit the half hand; but it contracted again as soon as the hand was withdrawn, so that it was necessary to dilate the ring again and again. Reposition was accomplished with only moderate difficulty in the same manner that was employed in Case 1. The entire operation was completed in forty minutes. It was followed by slight additional shock. Six hours after operation temperature 99, pulse 126. Convalescence uneventful.

Alcohol Is a Poor Cardiac Stimulant.—Dr. J. H. Kellogg of Battle Creek declares in the *Lancet-Clinic* that the theory that alcohol is a stimulant was long ago rendered thoroughly untenable by a multitude of carefully conducted experiments on healthy subjects, showing that alcohol is always and in all doses a narcotic, and not a stimulant; that it depresses, and does not excite the heart and other vital organs; that it lessens vital resistance to disease; and that it is a toxic agent which the body must cast out, and not a food to be assimilated or a source of energy or an aid to any vital organ or function.

THE ROENTGEN METHOD AS A GUIDE IN OPERATING FOR LITHIASIS OF THE URINARY TRACT.*

CARL BECK, M.D.

Professor of Surgery in the New York Postgraduate Medical School and Hospital, Visiting Surgeon to the St. Mark's Hospital and the German Poliklinik.

NEW YORK.

It is one of the strangest phenomena in medicine that in the face of the most abundant proofs of reliability of renal skiagraphy, some of the best text-books still hesitate to recommend the method. Some others even openly warn the practitioner against it. This they do because authors have observed or heard of grave errors committed in its employment. Thus it is said, for instance, that skiagraphs taken by the "best experts" have shown renal calculi, while nephrotomy disclosed the absence of any concretion; and, on the other hand, that cases were reported, in which calculi were found at the operation after skiagraphy had failed to show evidence of their presence. None of these reports is well founded.

Whenever errors have been committed they were of the individual and not of the method, and this should not be held responsible. I have often admired the power of imagination of some novices in skiagraphic work, who demonstrated the outlines of calculi as well as of some abdominal organs to me, when I could only find the possible indications of a dense band of tissue or a spot in the plate or a button of the underclothing of a too modest patient.

Such visionary powers, while immensely useful in the art of Shakespeare or Goethe, can not be too strongly reprehended in the domain of science and in the field of the Roentgen rays.

Now, fortunately, skiagraphic technic is so much advanced to-day, that it stands in no need of the imagination. A definite diagnosis in suspected lithiasis can be made. In each and every instance, or in other words, a renal calculus must invariably show, provided calculus is there.

Lumbar exploration and similar procedures for suspected nephrolithiasis, advised in all text-books, are, therefore, no longer in order, the Roentgen method not only showing whether or not any calculi are present, but giving precise information as to their size, shape and number. It will also show whether there are any calculi in the ureter or bladder.

The revolution which the Roentgen method has wrought in this special field is as great as in that of the injuries and diseases of the bones, which, after years of struggling, thanks to the untiring efforts of a few imperturbable physicians, is gradually beginning to be appreciated by the profession at large.

The chemical composition of the calculi of the urinary tract determines the greater or lesser depth of their shadows. The greater their atomic weight, the greater their density, and consequently the more distinct the shadow. Thus, calculi composed of oxalate of lime show the most distinct shadows. Their shadows are even deeper than those of bone tissue. Next to them we find those consisting of phosphate of lime, while the uric-acid calculi give the faintest shadows.

In practice, however, we often find that calculi are not of one distinct type, and, if they are, layers of various degrees of density are observed. Two types are generally present, then one or the other character predominating. So it frequently happens that there is a nucleus of uric acid surrounded by alternate layers of the other elements.

This explains why, at least, some dense areas are found in all cases of renal calculus; the same is true when the calculi are of small size. The question of composition, however, is of less importance than that of bringing the calculous area as near to the plate as possible, and keeping the field absolutely quiet.

These two requirements are attained by the use of a tubular diaphragm, which offers another great advantage, that of permitting the passage of the focal rays alone, excluding those rays which emanate from the tub l wall.[1] The disadvantage of the tubular diaphragms is that only small areas can be shown at a time. This disadvantage is little felt in the representation of joints, etc., but in renal or biliary skiagraphy it may be responsible for missing the seat of the calculi.

It is evident, therefore, that in skiagraphy of the urinary tract a general exposure must precede that of a limited area, since it can not be known beforehand whether the suspected calculi were situated in one or in both kidneys, or in the ureters. In other words, the Roentgen plate must *a priori* include an area which is bounded by the eleventh rib and the crest of the ilium on one side and by the vertebræ and the anterior axillary line on the other. For this purpose, plates of the size 10x12 or 11x14 are required. Corresponding with each side of the body, wire letters are placed which serve as landmarks for comparison, and at the same time indicate the side of the body. This is emphasized for the reason that cases are reported in which it has happened that on account of the changed relations of the negative, the wrong side was incised.

A few more wire letters may be placed in the renal region, also serving as landmarks for the special exposure. It is useful sometimes to attach the same wire letters to the body by means of adhesive plaster strips and to skiagraph them together with the wire letters on the plate, thus being able to compare the relations of the landmarks of body and plate for better localization.

Now, while with the general tentative exposure, only faint outlines of the calculi are obtained as a rule, they may be distinct enough to show at what area the diaphragm should be adjusted best to attain the most distinct outlines.

If the large plate proves to be negative, although other means of examination point to the presence of nephrolithiasis (hematuria), both renal regions must be separately examined with the aid of the diaphragm, several exposures sometimes being required. This, of course, is troublesome, but in view of the great importance of a correct diagnosis, it can not be omitted. It happens rarely, however, that so many exposures are needed, as a rule, the two sufficing for information. In this manner I have also been able to show calcareous deposits which were produced by renal tuberculosis.

The *modus operandi* in renal skiagraphy is as follows: The general exposure is preceded by a thorough evacuation of the bowels, followed by the administration of a moderate dose of opium. The patient is in the dorsal position on a large plate covering both lumbar regions. For localization, a few wire letters are distributed over the plate, the R. (right side) and L. (left side) being placed directly underneath the outer surfaces of the lumbar regions, so that they appear on the integumental margins of the skiagraph. With a pair of calipers their distances from the spinal column and from the ribs are ascertained and transferred on the abdominal surface to be marked there for the proper adjustment of the diaphragm. The head and shoulder are elevated by a few pillows, while the chin touches the sternum. The knees, after being flexed, are well immobilized by sand bags. The exposure should last from five to eight minutes, in proportion to the thickness of the abdominal tissues to be penetrated. The vacuum of the tube should be soft. I prefer the self-regulating tube of Mueller for renal skiagraphy.

---

* This article was prepared to be read before the Section on Surgery and Anatomy of the American Medical Association at the Portland Session, July, 1905, but the author was prevented by sickness from being present.

[1] Archives of the Röntgen Ray, etc., London, February, 1905.

The criterion of a good plate is that the vertebræ, the eleventh and twelfth ribs and the outlines of the ileopsoas muscle can be clearly defined. On the other hand, a plate which shows a number of calculus-like shadows, but fails to represent these points, must be regarded absolutely misleading, and should never be used as a guide for operation. The only thing to do is to try a second and if necessary a third or fourth time, the latter, however, seldom being necessary in the hands of a man of little experience.

If the plate is good and shows the indications of calculi, the tubular diaphragm is applied now in the same position as advised for the general exposure, with the difference that the shoulder of the exposed side is elevated somewhat more. It is best pushed below the rib arch in an oblique direction in such a manner that its center corresponds with the landmarks indicated on the large plate. The oblique direction permits of pressing the diaphragm deeply into the abdomen, thus reducing the distance between it and the plate to a considerable extent.

The time of diaphragmatic exposure should be two minutes in thin and from four to five minutes in stout individuals.

If the large plate is negative, I resort to a diaphragmatic exposure nevertheless, and if this shows the criteria mentioned above distinctly, I can most positively assure my patient that he does not suffer from nephrolithiasis.

It is not desirable, however, that the bones mentioned should show textural details. As a rule, the longer the exposure lasts, the clearer the bones show and the less marked the calculi will appear.

From this we also learn that rules for the time of exposure can only be laid down in general, the instinct of the operator being an important factor in determining details.

These views apply much more to the technic of biliary skiagraphy. As I have so often emphasized, the reason why so many surgeons have tried in vain to reproduce the calculi is due to the simple fact that they use hard tubes which penetrate them, so that they on account of their small degree of density are irradiated away, so to speak. In all my successful exposures for biliary calculi the bones appear dark and especially show no textural details.

The same principles apply to the skiagraphy of the urinary bladder. Vesical calculi, however, can be well shown without the aid of the diaphragm. In stout individuals the diaphragm may be useful sometimes.

The patient is skiagraphed in the recumbent position, the center of the tube to be directed to the upper margin of the symphysis. A good vesical skiagraph shows the structures of the coccyx well. The sacrum should not show any details. By oblique irradiation, the shadows of the vesical calculi are generally found just below those of the coccyx. An oblique exposure should be made beside, because it may show whether the stone is free or encysted. If the patient bends slightly forward in the lateral position, the calculus, if free, sinks toward the anterior vesical wall and becomes conspicuous directly behind the anterior abdominal wall. If it is not free, it usually shows far back toward the sacrum, since encysted calculi are nearly always attached to the posterior vesical wall. If the stone is of very large size, or if a great number are present, the whole vesical space is filled up and displacement is not apt to occur.

So far as the diagnosis of the number, shape and position of the calculi is concerned, the Roentgen method affords more valuable means than the cystoscope, aside from the fact that a calculus imbedded in a diverticulum will escape the cystoscope, while the rays will always detect it. At the same time, it should be realized that skiagraphy is a far more comfortable procedure than cystoscopy. The time of exposure is two minutes in children and from three to four minutes in adults. A soft vacuum is just as desirable as in renal skiagraphy.

My experience with the Roentgen method has suggested to me that it is invariably necessary to skiagraph the renal regions whenever vesical calculus is suspected. Since I have made this a principle, I have found renal calculus whenever there was a concretion in the bladder. This is not strange, if we realize that most vesical calculi were originally formed in the kidneys. This also explains the frequent recurrence of vesical calculus after operation. Within the last year I have observed three cases in which I operated for recurrent vesical calculus. In all of them skiagraphy revealed the presence of nephrolithiasis.

The first case was that of a woman of 32, who submitted to lithotripsy a year before I saw her. She was greatly relieved at first, but nine months afterward began to suffer from frequent micturition and pain in the vesical region. Skiagraphy demonstrated the presence of a small calculus in the bladder and a larger one in the renal region. I removed the vesical calculus, but the patient felt so well afterward that so far she has not decided to be operated on for the nephrolithiasis. If the size of the renal calculi is such that they may pass the ureter, I do not regard the removal of renal calculi an imperative necessity, but advise antilithiatic medical treatment first, the effect of which is studied by the Roentgen method.

In another case, a man of 24 showed the same history. Suprapubic lithotomy two years before I saw him had brought complete relief, the symptoms of recurrence appearing a year afterward. Skiagraphy revealed a vesical calculus of moderate size and a triangular calculus of large size in the left kidney. The patient submitted to suprapubic lithotomy, and so far has not returned to me.

In the third case, that of a boy of 7, whose large vesical calculus was removed by suprapubic cystotomy three years ago, the relief was complete for about a year, when the patient again began to suffer from symptoms of vesical calculus. The parents at first were unwilling to permit of repeated surgical interference, and while hesitating, the patient became greatly emaciated, the symptoms of light urosepsis finally compelling the parents to give up their resistance. The skiagraph revealed the presence of vesical as well as renal calculi on the left side. Suprapubic cystotomy was performed at the Postgraduate Hospital, and gave immediate relief from painful micturition, but had little influence on the pyelitic symptoms. The extreme exhaustion of the patient seemed to me to be a contraindication to immediate nephrotomy, wherefore I tried to keep the patient up with stimulation, at the same time giving hexamethylenamine internally. Three weeks afterward, when the vesical wound was thoroughly healed, I resorted to nephrotomy. The large triangular calculus was tightly imbedded in the parenchyma, so that it had to be mostly shelled out with the knife. The patient was discharged from the hospital four weeks afterward.

A small calculus was found near the lower surface of the large renal concretion. It would most probably have formed the nucleus for a third calculous formation in the bladder if it had been removed. The calculi consisted of oxalate of lime and the outer layer showed a smaller degree of density than the inner.

In another case of great skiagraphic interest, the patient was operated on at the Postgraduate Hospital. The patient, a woman of 36, began to suffer from violent pain in the right lumbar region thirteen years ago. Examination of the urine revealed the presence of pus. Nephrotomy disclosed the presence of a calculus of moderate size surrounded by pus. It was supposed, then, that the calculus was the source of the suppuration, and consequently a speedy recovery was expected. This expectation was not realized, a fistula remaining. The patient improved considerably, but the fistula did not close, so that after a year had elapsed, nephrectomy was advised, to which the patient, however, did not submit because her general condition had become very good in the meanwhile and the discharge had decreased.

About a year later the fistulous tract closed, more pus appeared in the urine and the left side became painful. Left-sided nephrotomy was done, a large abscess being evacuated. The patient again improved and the opening closed, but the pyuria continued, the patient's condition varying considerably.

When I saw her for the first time I suggested skiagraphic examination beside the other modern diagnostic means (cryoscopy, ureteroscopy), but the patient said: "There is no necessity for examining for nephrolithiasis, because the stone I had was removed by the surgeon." I mention this as an interesting and misleading argument. I, of course, insisted on my proposition, and the skiagraph showed the faint outlines of four calculi in the right lumbar region. A second exposure with the diaphragm showed them very distinctly.

The calculi had to be shelled out with difficulty, the irregular surface forming an impediment. The perirenal structures were matted and hardened, a natural consequence of the long-standing suppuration and inflammation. The adhesions were so dense that the kidney could not be lifted out, and great care had to be exercised during the whole procedure. This observation is another point against the formation of normal blood circulation after decapsulation. One stone had a sharp triangular edge. Recovery took place in two weeks, the patient being able to go around at that time. Three weeks after the operation febrile elevations began and the left side became painful. An abscess formed which was promptly discharged. Exploration of the abscess cavity revealed the presence of a long sinus leading to the opposite side just in front of the spinal column. The patient improved slowly and is up at the present writing, the thorough closing of the wound being expected in a short time.

The epicrisis of this case suggests that nephrolithiasis existed at the time of the first operation, when the Roentgen method was unfortunately not yet available. The very able surgeon who operated at that time undoubtedly examined the kidney carefully, but was unable to palpate the calculi through the parenchyma. The advice given later, when the fistula did not close, suggests that he thought the kidney to be in a state of destruction rather than assumed the presence of the stone, which under the circumstances would have been most natural. Under the most careful wound treatment and the good care which the intelligent patient exercised, the fistula closed, but the pus became retained in the depth and probably found a way to the opposite side which necessitated the incision on the left side. It is evident that if the Roentgen method had been available at the time of the first operation, the remaining calculi which penetrated the whole kidney would have been recognized and removed at once, thus sparing years of suffering. It did not only reveal their number, but also their size and shape, and—last but not least—localized them. After the surgeon has removed the calculi, which are easily identified with those of the plate, no further searching is required, as it was imperative in former years, when the kidney had to be nearly dissected in order to ascertain whether there were any additional calculi left.

INFLAMMATION OF THE EYE DUE TO THE TOXINS OF THE GONOCOCCUS.

SWAN M. BURNETT, M.D., PH.D.
Professor of Ophthalmology and Otology, Medical School, Georgetown University.
WASHINGTON, D. C.

IRITIS.

Under the name of metastatic ophthalmia, or some other such synonym, inflammation of the iris has long been recognized among ophthalmologists as a possible accompaniment of gonorrheal urethral infection. There is scarcely a treatise on diseases of the eye since McKenzie's time, but speaks of it in a more or less extended manner.

The iritis is commonly regarded by ophthalmic authorities, as a part of an intoxication which manifests itself under the form of rheumatism; at least, few cases have been reported which have not been associated with greater or less pronounced symptoms of a rheumatic nature—usually affecting the joints.

Whether the intoxication in these instances is from an entrance into the circulation of the gonococcus itself or from the product known as the toxins, has not been definitely settled to the satisfaction of all. Further investigation and observation along this line are needed. The fact of the association of the diseases with gonorrheal infection, however, is no longer disputed.

As to the frequency of gonorrheal iritis, all authorities are not agreed. By some it is considered as extremely rare. De Lapersonne[1] of Paris, for instance, who is one of the latest writing on the subject, states that he sees only one or two cases in every 7,000 new patients at the Hotel Dieu. Some others, however, seem to regard it as rather common. This discrepancy may be accounted for by the fact that the complication is more frequent in some localities than in others, or, what is more probable, by a failure on the part of some clinicians to inquire into the existence of gonorrhea in the cases of iritis which come under observation. It is a fact not without bearing on the point of frequency, that from the large clinic for genitourinary disease at the Central Dispensary and Emergency Hospital, where my own clinic is located, there has not been a single case of gonorrheal iritis referred to my service during the last twenty-five years, while cases of iritis from syphilis have come to me from that clinic in large numbers. It may be of interest to know that the genitourinary clinic is largely recruited from the negroes, among whom gonorrhea is most rife.

---

[1] Archiv. D'Ophth., March, 1905.

The forms under which gonorrheal iritis may appear are various. It may be the so-called spongy iritis with a deep anterior chamber and dilated pupil, or any of the plastic varieties with various kinds of exudate, and even the hemorrhagic form has been mentioned. The so-called spongy iritis, such as was present in the case to be described, while one of the rarest forms of iritis to be met, generally finds its place here, I think, with greater comparative frequency than the other forms. As another distinctive feature of gonorrheal iritis may be mentioned its tendency to recurrence during the same or subsequent attacks of gonorrhea. The same holds true of the common rheumatic form. The disease may be very intense in its manifestation or mild and slow in its progress. Almost without exception, both rheumatism and iritis show themselves during the declining stage of the urethral disease, quite contrary to what would be expected. One or both eyes may be affected at the same time or in succession.

It seems singular and altogether quite unaccountable that while gonorrheal iritis finds at least a mention in practically every text-book of importance on diseases of the eye, it seems to be completely ignored in all the treatises on genitourinary diseases which I have been able to consult, with the exception of two American text-books.[1]

It is, therefore, not without justification that the subject is brought more closely to the attention of the general practitioner and genitourinary surgeons among whose patients the disease shows itself primarily, and in whom a correct diagnosis should first be made, and, of even more importance, a proper treatment promptly begun. A careless or not sufficiently informed practitioner, not being aware of the possibility of iritis as a complication of gonorrhea would naturally look on any redness or infection of an eye as a beginning conjunctivitis due to an external infection, and treat it as such with astringents and antiseptics, probably for some days, so that by the time the real condition becomes known irreparable damage would already have been done. As is well known, it is more than usually necessary that in iritis the use of a mydriatic be begun early in order to secure at once as full a dilatation of the pupil as possible—since, otherwise, permanent adhesion to the anterior capsule of the lens or complete closure of the pupil is almost certain to occur. A day or two, or even a few hours' delay, may mark the line between the preservation of good vision and partial or even complete blindness. As a clinical contribution to the study of this form of disease the following history is offered:

Patient.—J. A. D., a young white man aged 22, came to me on Oct. 6, 1904, complaining of his eyes, which he said felt uncomfortable but not painful, and as he had been suffering from gonorrhea for some three weeks, he was fearful that this might be the beginning of a gonorrheal conjunctivitis, as he was aware that "gonorrhea often affected the eyes."

Examination and Treatment.—As the conjunctiva was clear and the pupils responded promptly to light, I assured him that there was no inflammatory trouble, but, as an examination revealed myopic astigmia of 0.5 D. with the rule, he was ordered correcting glasses, which gave $V = 5/5$ in both eyes.

Subsequent History.—On October 7 there was some slight injection of the right eyeball, the vessels being fine and coming up to the corneal edge; no mucus or pus. There was no pain and the pupil reacted well to light. He was ordered to make hot applications to this eye and to abstain from work. This condition continued about the same with clear media and a normal fundus until October 12, when the bulbar congestion increased, but with no complaint of pain. Atropin gr. ii to aqua ʒi, was then ordered in addition to the hot applications.

October 13: When he awoke he found that his vision was almost entirely gone. An examination revealed great muddiness of the anterior chamber and a rigid but fair-sized pupil. The fundus could not be made out in any detail, only a dull diffuse redness being visible under the illumination. An examination with the binocular magnifier showed many fine fibers coming out from the pupillary space and reaching to the posterior surface of the cornea. The strength of the atropin was increased to gr. iv to aqua ʒi, a drop in the eyelid three times a day, and dionin (ethyl-morphin hydrochlorate), 5 per cent., was used. The diagnosis of spongy iritis was made.

October 14: The mass in the anterior chamber had assumed its characteristic gelatinous appearance, filling the anterior chamber except for a small section above. The edge of the exudate, as is always the case in spongy iritis, was sharply marked and the mass could be seen to extend from the iris to the cornea, occupying the entire depth of the chamber. The size of the pupil remained about the same.

October 15: There was a still further diminution in the exudate, principally above, so that the pupil was somewhat uncovered.

October 16: All that remained of the exudate was a band about 2 mm. broad with sharp edges, occupying the center of the pupil from above downward. It had some fine offshoots connecting it with the pupillary edge above and below. The iris itself had a clean, unswollen look, the natural rugæ showing up plainly. The pupil was larger and vision was returning. There was still no acute pain complained of, only some slight frontal headache. The conjunctival injection, while pronounced, was not excessive and there was little or no chemosis.

October 17: The pupil was dilated *ad maximum* and the exudate was found to be all gone except a few spots on the anterior capsule of the lens. The fundus could be seen but rather dimly.

October 23: The lens was entirely clear and the fundus only slightly hazy, $V = 5/20$. In the course of ten days more every vestige of the disease had disappeared and vision was normal. Since then there has been no further trouble in either eye. The patient's gonorrhea has also disappeared.

Special inquiry was made as to the manifestations of rheumatism and it was found that some days before the appearance of the uncomfortable feeling in his eye he had a pain and some swelling in the joints of the big toe of the left foot. While not severe, these symptoms were present during the whole course of the eye affection.

---

[1] An examination was made of all the treatises on genitourinary diseases to be found in the library of the Surgeon-General's office with the following result:

Morrow: "System of Diseases of the Genitourinary Organs," New York, 1894.. No mention. Stokes, F. W.: "Diseases of the Genitourinary Organs," London, 1892. No mention. Taylor, R. W.: "A Treatise on Genitourinary and Venereal Diseases," New York and Philadelphia, 1904. No mention. Fuller, Eugene: "Diseases of the Genitourinary System," New York, 1892. Simply mentions it. Will-Ogilvie-Lectures on Genitourinary Diseases, London, 1894. No mention. Acton, W.: "The Diseases of the Genitourinary Organs." Philadelphia, 1888. No mention. Belfield, W. S.: "Diseases of the Genitourinary Organs," New York, 1884. No mention. "American Text-Book of Genitourinary Organs." Philadelphia. No mention. Black, D. C.: "Diseases of the Genitourinary Organs," Philadelphia, 1872. No mention. Guthrie, G. J.: "Genitourinary Diseases," London, 1836. No mention. Morris, H.: "Diseases of the Genitourinary Organs," London, 1895. No mention. Hyde and Montgomery: "Syphilis and Venereal Diseases," Philadelphia, 1900. Quite a full account of eye affections occurring in gonorrhea under the heading of gonorrheal rheumatism—not, however, placed in the index separately.

E. L. Keyes and E. L. Keyes, Jr. "Surgical Diseases of the Genito-urinary Organs," New York, 1903. A full account, similar to the above, of iritis and conjunctival affections in gonorrhea, considered under the heading of gonorrheal rheumatism. Not indexed separately.

CONJUNCTIVITIS.

The existence of conjunctivitis due to an endogenous infection of gonorrheal toxins is certainly rare, and is questioned in many quarters. Before the era of close bacteriologic study it is quite possible that cases of this kind may have escaped observation, since it would be only natural to refer any conjunctival inflammation with a mucopurulent or purulent discharge to an external infection. The case here reported might easily have been classed as an ordinary gonorrheal infection of the conjunctiva had I not followed my invariable custom of examining all conjunctival discharges as to their bacteriologic character.

Patient.—R. C., white, aged 25, came to me on May 22, 1905, with a double mucopurulent conjunctivitis.

Examination.—There was but slight swelling of the lids. The cornea was clear and the iris and other internal structures normal. He first noticed a discharge from his eyes two days ago. As he confessed to having a slight gonorrhea (a second attack), an external infection was considered almost certain. Nevertheless a smear of the discharge was taken. He was given a cleansing wash, to be used three times a day. An examination of the slide by Dr. Le Merle at the Lionel laboratory at the Emergency Hospital failed to reveal any organisms of any kind. The specimen was pure mucopus.

Course of the Disease.—May 24: There was quite considerable thickening of the conjunctiva of the lids. The eyeball itself was not entirely free from infection, and there were a few fine ecchymoses of the conjunctiva near the cornea in both eyes. The discharge was about the same—not creamy, but stringy and in rolls. On May 28 another careful examination of the discharge was made, with the same result as before—no organisms of any kind whatever were found. By May 30 the discharge was much less, and the infection of the ball quite gone.

Remarks.—By June 1 the eyes were practically free from discharge, though there yet remained some thickening of the conjunctiva of the lids, particularly the lower retrotarsal folds. An inquiry into his history revealed the fact that when he had his first attack of gonorrhea, two years ago, about three weeks after the beginning and when it was in the stage of decline, he was seized with rheumatism in the left foot which laid him up for three weeks. During his present attack he has had pain and tenderness of the patellar ligaments of the left knee—not severe, but sufficient to keep him reminded that he has a knee joint.

I am aware, of course, that it may be charged that there is little evidence, beyond that of coincidence, that the conjunctival inflammation was due to an endogenous affection. An external affection, however, I think, can be positively excluded, and we should at least learn from this the importance of a bacteriologic examination in every case of purulent conjunctivitis occurring in gonorrheic patients. If no gonococci are found, the prognosis is quite different from that when their presence is demonstrated.

External inflammations of the eye in gonorrheic infection have been observed and commented on by both ophthalmic and genitourinary authors. They have generally been described as of a mild type.

Taylor, who is one of the few who mention it at all, in his "Text-Book on Genitourinary Diseases," 1904, has characterized it as "serovascular conjunctivitis." Others evidently regard it as a form of scleroconjunctival affection. No author I have been able to consult has mentioned the pronounced mucopurulent form here described. While it is quite true that most of the complications of general gonorrheal infection show themselves under the form of the so-called rheumatic inflammation, that is a plastic form affecting the fibrous structures, there are certain instances in which it assumes the purulent form, as in cases of endocarditis that have been reported. A more careful examination and observation of cases of purulent conjunctivitis in gonorrheic subjects would throw much needed light on this subject, which has an important pathologic, as well as a highly practical interest.

THE MEDICAL FEATURES OF THE PAPYRUS EBERS.*

CARL H. VON KLEIN, A.M., M.D.
CHICAGO.

This is an age of inquiry in researches and excavation, with a constant craving for some new development to assist us in our studies.

The last hundred years is the Niobe of civilization, not only in inventions and productions, but in the remarkable revelations which have materially assisted us in the wonderful development in science. However, whatever we have done to advance the history of civilization was not done by an easy task.

When we look through the magnificent works of discoverers and pioneers, the fruit of hardship, trial and labor, we can not fail to be infected with some of the enthusiasm which animated those who were endowed with superior intelligence and the gift of knowledge to bring forth hidden treasures from the inmost bosom of the earth, and to transmit them to future generations. Of one of these it may well be said: "From the Orient to the Occident," great be thy name (George Ebers).

The Anglo-Saxon nations, though renowned for deep thinking, and philosophizing in every branch of science and art, can not boast of a scholarship in bringing forth the first literature of the science of medicine. A third of a century has elapsed since George Ebers revealed the pages on medicine which were written some seven thousand years ago, and which were concealed for nearly four thousand years between the legs of a mummy. With the assistance of the learned Ludwig Stern and other Egyptologists, Ebers published the fact that Hippocrates of Cos, who for twenty-three hundred years has been known to the world as the "Father of Medicine," and as an original observer, no longer possesses this distinction. It has been wrested from the ancient Greek by the discovery of this papyrus of a date so remote as almost to place Hippocrates within the ranks of modern physicians.

However great the appreciation we may manifest, it is but strictest justice to do homage to the zeal, the remarkable ability and indefatigable activity of this German scholar, whose name is attached to that elaborate work, the "Papyrus Ebers."

The revelation of this important document merits assuredly all praise. In the Ebers Papyrus we have a monument of ancient culture before us, whose medical and historical value is inestimable, as may be seen from the description of its contents.

In this complication we have the most important medical treasure of the Egyptians before us, in a more complete form than any other known work. We learn much, too, of the anatomic, physiologic, pathologic and pathologico-anatomic conception of that time. Furthermore, it gives us information concerning the methods of the examination of a patient and diagnosis of the Egyptian physicians, of methods of teaching and learning, as well as of the medical standing at that time.

---

* Delivered before the Thirtieth Annual Session of the American Academy of Medicine at Chicago, 1905.

DISCOVERY OF THE PAPYRUS.

No better history can be attempted than the one given by the illustrious Ebers[1] himself, which possesses all the characteristics of a romance.

In the winter of 1872-73, George Ebers and his friend, Ludwig Stern, of the University of Leipsic spent several months at Thebes in quest of rare documents. For some time the two scientists made their dwelling place in one of the tombs of Abd-el-Gurnah, and associated daily with the Arabs of Luxor. A wealthy citizen of that place showed Ebers the antiquities which he, little by little, had obtained from a fellah, on the other side of the Nile. One day he exhibited one of those texts that are known under the name of "shai-en-sensen," and a wooden Osiris statuette in which a papyrus was well concealed. As an Arab did not trust himself to unfold the perishable manuscript, Ebers bore in mind the "shai-en-sensen," and let its high-priced possessor know that similar texts known had been found, and that he could not consider its purchase without seeing the contents of this papyrus, but that if he had anything really valuable or rare to offer him, he would not hesitate to pay him well for it. The next day the Arab sent for Ebers and took from a tin case a well-preserved papyrus roll. According to the statement of the Egyptian possessor, the papyrus was found in a tomb in the so-called Il Assiût part of the necropolis of Thebes, between the legs of a mummy. Since the finder of the latter was dead, it was impossible to refer to the exact tomb that formerly contained the treasure.

The costly manuscript was unfolded and on close inspection Ebers made the startling discovery that it was a document of great value and in an unusual condition of preservation. Ebers says he can with difficulty describe the impression that the precious, delightfully written and undamaged memorial made on him. The first lines on which his eyes fell belonged to a fragment of a calendar that he had known for a long time. This little document, so very important to the Egyptian chronology, was years ago shown to the renowned Egyptologists, Dümchen, Naville, Brugsch, Eisenlohr, and in 1870 to Ebers himself, in a copy belonging to a Mr. Smith, an American inhabitant of Luxor, who maintained that he was the possessor of an extensive medical papyrus. Because of an affection of the eyes contracted while copying inscriptions, Ebers could not study the Smith copies; hence Professor Eisenlohr of Heidelberg succeeded in obtaining a drawing (by means of tracing) of the fragment of calendar which was then regularly advertised in a periodical devoted to the Egyptian language and archæology, but without success.

Outside of the already-mentioned fragment of calendar, not a line of the papyrus was known. Mr. Smith claimed to have possessed a roll from which he had copied the fragment of the calendar, while, in reality, he possessed only a copy, which was the product of his own handwriting.

Thus Ebers knew the true possessor of the precious memorial, and he resolved from the first to obtain it. The required price was high, but not higher than that paid for less handsome papyri. The same winter an Englishman of the British Museum was traveling through Egypt, and being aware of the treasure at Thebes, intended to purchase the same from Mr. Smith, whom he believed the true possessor. Ebers longed to possess the document himself, but had not the means to meet the demands of the owner, who was not altogether aware of its full value. However, receiving the financial assistance, graciously advanced to him by Max Günther, privy councilor of commerce at Leipsic, then visiting the Egyptian monuments, Ebers purchased the treasured papyrus.

With the newly acquired treasure on board, they sailed for Cairo, where they had an opportunity to glance over the contents of the fragile roll. His friend, Professor Stern, remained behind. Ebers traveled homeward, and ended the work which he later showed and explained to His Majesty, the lamented King John of Saxony, a man of letters in the broadest sense of the term. It was finally turned over to the University of Leipsic for safe-keeping.

In order better to preserve the valuable antiquity, and so that it may be shown to the many visitors, it has been cut into twenty-nine pieces of different sizes. Each piece lies under a glass, so as to avoid pasting. Those written on both sides are placed between two glasses.

DESCRIPTION OF THE PAPYRUS.

When Ebers came into possession of the papyrus, it consisted of a single, tightly rolled piece of the finest yellow-brown papyrus. The width of the document was 30 centimeters, and the length of the written part 20.23 meters. No other papyrus known to Egyptologists is better preserved.

The text of this perfect ancient record is divided into columns, each of which is numbered. The column numbers are placed over the first line in the middle of each column, which contains either twenty-one or twenty-two lines. With the exception of columns three to twenty-one, which are considerably smaller, the columns are 22 centimeters in width, and run from 1 to 98, and in the back from 99 to 110. Singularly, the numbers 28 and 29 are missing, although the text continues uninterruptedly. The omission is explained on the ground that the Egyptians considered 110 to be a perfect number, and by this means the writer was enabled to complete his book with the required number of pages.

Dr. von Oefele believes the writer was a very fine caligraphist, but evidently a very ordinary and careless subject, and therefore carelessly skipped from number 27 to 30.

There is no lack of figures in the text, and only a few that are repeated time and again, and they are written in red to denote the quantity of the medicament to be used, while the prescriptions are in black. Another particular feature of the pagination is that up to column sixty the same hand paged the papyrus, while another scribe continued in the pagination in a different manner, although the text shows that it was wholly written by one person only. The second pagination may be the work of the physician who added his ( ) signature after many a prescription, or the purist, who wisely added his signature in paler ink, when that of the physician was omitted.

Script.—The script in which the Ebers Papyrus is written is extraordinarily regular, partly in black and partly in red ink. This form of writing is known as the hieratic, and is one of the three forms used by ancient Egyptians. The others are the hieroglyphic and the demotic. The hieratic is the cursive form of Egyptian writing, and is used chiefly on sacred and medical papyri and on wooden coffins. How early the hieratic came into use is unknown, but fragments of papyri in script with those characters have been traced to the I. dynasty. The characters are usually written from right to left. The invention of this script was attributed to Thoth (the Greek Hermes), and was in constant use up to about 100 B. C.

---

[1] Papyrus Ebers, vol. 1, Leipzig, 1875.

About 300 A. D. all knowledge of the meaning of the characters had died out, and it was not until the discovery in 1799 of the Rosetta Stone (by Boussard, a French artillery officer) that any real progress was made in their decipherment.

Rubic or red occurs in almost every heading throughout the papyrus. Also in the statement of the disorder for which a medical prescription is to follow. Those headings, or rubrics, as they are called, show the use of red colors for such purposes in the most remote antiquity. Dr. Christen,[2] in a chemical analysis of this red coloring, found it to contain red lead.

Synonyms.—In the Ebers papyrus there exist a great many synonyms which are so much like the Semitic vernacular, both in expressions and pronunciations, that one is almost led to believe that the ancient Egyptian belongs to the group of Semitic tongues. The language of the papyrus with all its richness of primitive forms possesses such organic arrangements that a single word can be easily recognized, for if a branch of the same is lacking, it may be readily supplied by one from another dialect. Sometimes an abstract conception or a mental function is combined with different things or actions, perceptible through the senses; ordinarily, therefore, things are easily explained; substances of either material or spiritual character are represented according to their characteristics. Each noun contains one of those characteristics; therefore, there exist as many nouns for the same thing as there are characteristics in it. One of the characteristics of the Egyptian, as well as of the Semitic tongues, is that they had different ways to arrive at the expression of the conception, which, however, were not identical in meaning. It is difficult, therefore, to differentiate the co-existing synonyms. Philologists regard the various shades in order to explain the origin of a conception from different sides.

Age of the Papyrus.—The exact date of the writing of this papyrus has not yet been established. Carious opinions exist. The calendar which is on the outside of the papyrus refers to the eighteenth dynasty, in the sixteenth century B. C., and bears the following inscription: "In the ninth year of His Majesty the King of Upper and Lower Egypt, Amonophis I, the Everlasting." Before the last epithet is the framed name of the king.

The Date of Transcription.—According to Lenormant,[3] a royal library was established at Thebes 1670 B. C. (near the place where the Ebers Papyrus was found), under the direction of Amen-em-an, who took great pride in transcribing fragile papyri, which was at that time falling into decay. Therefore, it is possible that the Ebers Papyrus was either compiled, revised or rewritten in 1552 B. C., or 118 years after the establishment of the library. There is still another important supposition concerning the Ebers Papyrus. According to the discoverer's opinion, it is identical with the hermetic books Περὶ φαρμα'κων which are quoted by Clemens Alexandrinus.[4]

The latter is said to be the greatest of all works deposited in the tomb of Osymandias at Thebes, which, according to Diodorus Siculus, contained 20,000 volumes. Among these were the forty-two hermetic books described by Clemens Alexandrinus, six of which were medical works, on the structure of the body, on diseases, on instruments, on medicine, on the eyes, and on women.

Hermetic, which means compiled, or inspired by Thoth, was any work which was written by a priest according to the inspiration of the god, which would correspond excellently to the Ebers Papyrus. However, Lüring[5] believes that the Ebers Papyrus is much older than the book, and argues that there are certain remarkable differential points between them. Whatever may be the truth, the value of the Ebers Papyrus is the same, be it the hermetic work or a compilation from writings of prominent physicians of the earliest ages.

That the writer of the Ebers Papyrus wrote in 1552 B.C. can be proved in three ways, as Ebers[6] shows, namely, first, by the peculiar shape of the letters in which the manuscript is written; second, by the names of kings occurring in the papyrus; and third, by the calendar which we find at the back of the first column of the roll.

The name of the king in whose reign the Ebers Papyrus was transcribed, compiled or written was Amenophis I of the eighteenth dynasty.

von Oefele[7] calls attention to the fact that the language from columns 103 to 110, which are written on the back of the papyrus, is different from that of the rest of the roll, although the handwriting is the same and shows that there existed different dialects in the land of the Pharaohs, the same as exist to-day in many countries. Dr. von Oefele further states that while the style of writing in the Ebers Papyrus does not go back beyond 1600 B. C., yet the text, in other words, the idioms of the language, belong to a much older period, and that the oldest portions of the Ebers Papyrus very likely reach back into the time of the first Egyptian dynasties.

Lepsius[8] and Meyer[9] believe that it was not only written, but also compiled under the government of an unknown Hyksos king. It is thus generally accepted that the Ebers Papyrus is a copy. Moreover, the many corrections made by strange hands and the many critical, marginal notes found throughout the papyrus show that the document was worked on.

CONTENTS OF THE PAPYRUS.

A large proportion of the diseases known to modern medical science are carefully classified and their symptoms minutely described.

Mention is found of the following diseases, with their treatment:

Diseases of the Abdomen.—Abdominal tumors and swellings, obstructions of the abdomen, swellings in the inguinal region, affections of the stomach, esophagus, pylorus and small intestine, obstruction of these organs, inflammations, diseases of the liver, affections of the intestines, intestinal worms, belching, cramps, jaundice, and chlorosis—Ægyptiaca.

Diseases of the Bladder and Urinary Organs.—Obstruction of the urinary passages, cystitis, retention of urine, polyuria, hematuria, diabetes mellitus, blood in the urine, hypertrophy of the prostate, stricture, dysuria, and strangury in children.

Diseases of the Rectum and Anus.—Tumors, inflammatory abscesses, prolapsus, affections of the vessels, inflammations, obstructions, diarrhea, dysentery, constipation, and pain.

Diseases of the Chest and Respiratory Organs.—Diseases of the bronchi, affections of the lungs, asthma, phthisis, general diseases of the chest, and sequels to diseases of the stomach.

[8] Ægypt., Zeit., 1875, p. 145.

[9] Gesch. d. Alt. I, section 402.

Diseases of the Heart.—Fatty degeneration, dilatation, carditis, angina pectoris, hypertrophy, thrombosis, and anasarca.

Diseases of the Eyes.—Conjunctivitis, iritis, blear eyes, hyperemia, granulations, albugo leucoma, vascular cicatrix of the cornea, corneal opacity, staphyloma of the cornea, inflammation, myiodeopsia, hypopyon, stenosis, contractions, strabismus, xanthelasma, fatty degeneration, abscesses, chemosis, suppuration, amaurosis, amblyopia, cataract, paralysis, blepharitis, injury, calcification of the Meibomian glands, distichiasis, and trichiasis.

Diseases of the Ears.—Impaired hearing, inflammation, viscous humor, suppuration, fetid pus, and foreign bodies.

Diseases of the Nose.—Tumors, coryza, influenza, and mucus.

Diseases of the Head and Neck.—Tumors, migrain, neuralgia, shooting pains, and vertigo.

Diseases of the Scalp.—Tumors, alopecia, superfluous hair, and eruptions. There are also prescriptions to prevent hair from turning gray, to produce its growth on bald heads, to promote the growth, to make it grow on cicatrices, to depilate the scalp, to prevent white hairs from coming in the eyebrows, and to dye the hair.

Facial Diseases.—Sunburn, freckles, wrinkles, discoloration, roughness, and blotches.

Diseases of the Tongue and of the Teeth.—The ailments of the tongue are not specified, but for the teeth there are prescriptions to strengthen them, to make them grow, to heal ulcers of the gums, swelling of the gums, and bloody congestions of the teeth.

Diseases of the Skin.—Pains, pustules, prurigo, swellings, tumors with fetid suppuration, lesions, fistulas, leprosy, eczema, scabies, rashes, itching, burning, cankers, boils, carbuncles, and furuncles.

Diseases of the Blood, Arteries, Veins and Nerves.—*Distoma hematobium*, extravasations, congestion, coagulation, numbness of the vessels, loss of suppleness, and weakness of the nerves.

Sores and Wounds.—Blows that have cut the flesh, blood in the opening of the wound, gangrene, eschar formation, pus, contusions, cuts, pricks, bites of man or beast, thorns, splinters, etc., and their treatment.

Burns.—Sores which result from burns, poisonous burns, spots or white cicatrices which such sores leave, and alteration of the hair on the burnt surfaces.

Diseases of the Limbs.—Trembling, pain, swellings, stiffness, bent limbs, itching, tumors, lesions, *Filaria medinensis*, tired limbs, perspiration of the feet, sore toes, corns, bunions, callosities of all sorts, and falling nails.

Diseases of the Female Genitals.—Tumors and abscesses in the vagina, inflammation of the vagina, twinges in the vagina, chafing due to inflammation in the vagina, ulceration of the womb, pain in the labia, abscesses of the labia, menstrual disturbances, *fluor albus*, affections of the mammary glands, etc., and their treatment.

Maternity.—Methods to induce abortion, to prevent abortion, to replace a prolapsed uterus, to deliver a woman, to perform version during delivery, to deliver the placenta, to restore the vagina to its normal condition, to prevent retention of urine, and to stop hemorrhage.

Hygiene.—Deodorizations, fumigations of dwellings, perfumes for women to render odor of the house, clothing and breath agreeable, to destroy insects, reptiles, plant lice, to prevent wasps and mosquitoes from stinging, to prevent mice and rats from gnawing things, to prevent birds from eating crops, to prevent rodents from devouring corn in the granary, and to destroy lizards and scorpions.

Not only diseases producing suffering to mankind claimed the physician's care in those days, but he had also to consider the toilet. Seventy-four prescriptions pertain alone to hair washes, dyes, oils and depilatories. After duly reflecting on important anamnestic facts, on the subjective disturbances or disorders, and the objective or demonstrable changes, the physician prescribed the treatment, and a remedy which was either aimed at the principal subjective disturbance of the patient, or at the most striking objective manifested symptom, and often symptoms of the disease were regarded as the disease itself. It is not improbable that in difficult cases consultations were held.

In this papyrus are mentioned over 700 different substances from the animal, vegetable and mineral kingdoms which act as stimulants, sedatives, motor excitants, motor depressants, narcotics, hypnotics, analgesics, anodynes, antispasmodics, mydriatics, myotics, expectorants, tonics, dentifrices, sialogogues, antisialics, refrigerants, emetics, anti-emetics, carminatives, cathartics, purgatives, astringents, cholagogues, anthelmintics, restoratives, hematics, alteratives, antipyretics, antiphlogistics, antiperiodics, diuretics, diluents, diaphoretics, sudorifics, anhidrotics, emmenagogues, oxytocics, ecbolics, galactagogues, irritants, escharotics, caustics, styptics, hemostatics, emollients, demulcents, protectives, antizymotics, disinfectants, deodorants, parasiticides, antidotes and antagonists.

Medicines are directed to be administered internally in the form of decoctions, infusions, injections, pills, tablets, troches, capsules, powders, potions and inhalations; and externally, as lotions, ointments, plasters, etc. They are to be eaten, drunk, masticated or swallowed, to be taken often, once only—often for many days—and the time is occasionally designated—to be taken mornings, evenings or at bedtime. Formulas to disguise bad-tasting medicaments are also given.

The Ebers Papyrus contains numerous other subjects pertaining to the practice of medicine, which the reader will find in the text.

TRANSCRIPTION FROM HIERATIC TO HIEROGLYPHIC.

In 1874, two years after the discovery of the papyrus, at the Orientalists' Congress, held in London, a method of transcribing hieratic texts into hieroglyphics was devised. Ebers, in working on the papyrus, has followed this method in general, still he transcribed a few signs, especially those which seem to indicate vowels, independently of the London method. The latter, accepted in the main by all orientalists, has been modified in its details by all Egyptologists, so that in every work on this papyrus we meet with various interpretations of the written characters.

In 1875 Professor Ebers, with the financial support of the Royal Saxonian Ministry of Education, had reproduced *fac simile* photo-lithographic plates in size, dimension and color, in two magnificent volumes, in large royal folio, illustrated after the hieratic text.

Volume I contains an introduction written by Ebers himself, a general index of the titles of all the subjects, with explanatory notes and plates I-LXIX. Volume II contains an hieroglyphic and Latin glossary of all Egyptian words alphabetically arranged, with reference to the columns and lines where they are found, and plates LXX-CX. Much credit is due both George Ebers and his traveling companion and assistant, Ludwig Stern, librarian of the vice-royal collection of manuscripts in Egypt, for the reproduction and the translation from a language of which so little is known. The study of Egyptian literature, as a whole, is hardly more than three-quarters of a century old, and too much praise can not be given Prof. Ludwig Stern for his labor and the pains taken in the compilation of the special glossary annexed to this beautiful work, which will ever remain an honored testimonial and a monument to both immortal names.

OTHER PAPYRI AND MEDICAL ANTIQUITIES.

There are now in existence seven papyri on the subject of medicine, those at Berlin (large and small), London, Leyden, Turin, Bulak and Leipsic, the last being the Ebers Papyrus, which, because of its rich contents, the distinctness of its script and its completeness is foremost in importance.

In order to fill the vacuum between Ebers Papyrus and the writings of Hippocrates, we must not overlook the inscription on one of the "Mastabas," or tombs of Egyptian grandees, which surround the pyramids of Sakkarch, that of Sekhet-enankh, chief physician of the Pharaoh Sahura of the fifth dynasty, 3533 B. C. It describes how he healed the king's nostrils, for which his majesty wishes him "a long life in holiness"; and the compilation of medical works assigned by tradition to one of the most ancient kings, Teta, the successor of Menes of the first dynasty. Manetho,[10] the Egyptian priest and historian, tells us that this king wrote treatises on anatomy and surgery and performed surgical operations with flint flakes. About 3300 B. C., during the reign of Cheops, the builder of the great pyramid, a medical papyrus containing anatomy was found by a priest in a temple. We also know that the Egyptians practiced embalming for over 5000 years B. C., and their process surely necessitated a knowledge of anatomy. There can be no doubt, therefore, that this ancient people knew the structure of the body, and without that knowledge they could not have understood even the symptoms of the different maladies enumerated in the Ebers papyrus.

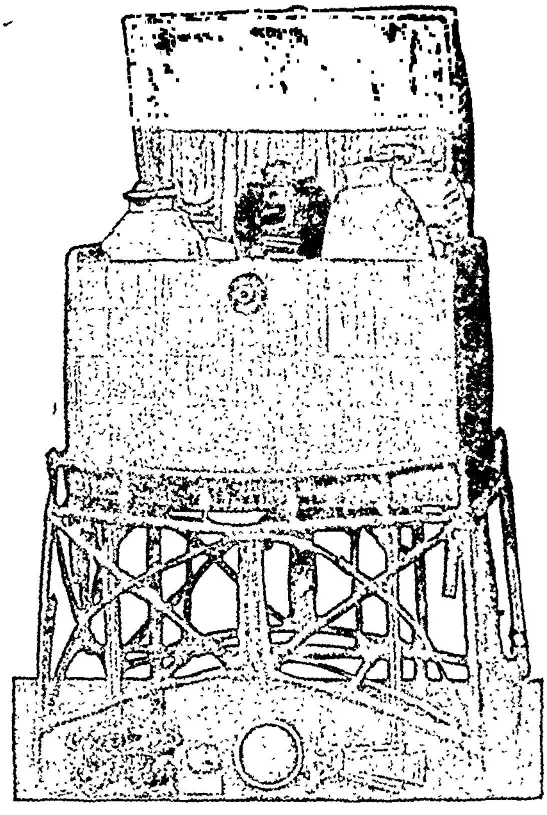

Fig. 1.—A domestic medicine chest of an Egyptian queen.

Pliny (XIX, 5) tells us that the Egyptians examined the bodies after death, to ascertain the nature of the diseases of which they died. There may have been a prejudice against it, perhaps, just the same as there is to-day, but the Egyptians did not shrink from human dissection, consequently the study of anatomy was a matter of course. However, they may not have attained the degree that we might expect in comparison with their other medical knowledge.

Another relic of Egyptian medicine is the domestic medicine chest (Fig. 1) of the wife of the Pharaoh Mentu'hotep of the eleventh dynasty, 2500 B. C. It contains six cases, one of alabaster and five of serpentine, with dried remnants of drugs, two spoons, a piece of linen cloth and some roots, enclosed in a basket of strawwork. It was found in the queen's tomb (Fig. 2).

Beginning with the earliest chronology on the existence of Moses, or his five books in the Bible, and considering the doubtful authority and the most accepted authority, namely, Josephus, who believed that Moses wrote Exodus about 1985 B. C., and Bunsen, who stated that Moses died 1523 B. C., we observe a difference of 462 years in the dates assigned to the life of Moses, hence between the two authorities we naturally come to the conclusion that the five books of Moses must have been written between 1985 B. C., and 1523 B. C. Hence, as between the oldest and the latest parts of the Ebers Papyrus lies a vast space of time, over 3,000 years, the whole dating from various epochs between 4688 B. C. and 1552 B. C., it appears reasonable to conclude that Moses knew Egyptian medicine. Medical literature was considered sacred, and therefore was carefully guarded from the profane eyes of the laity, and was only open to members of the priest class and their matriculants.

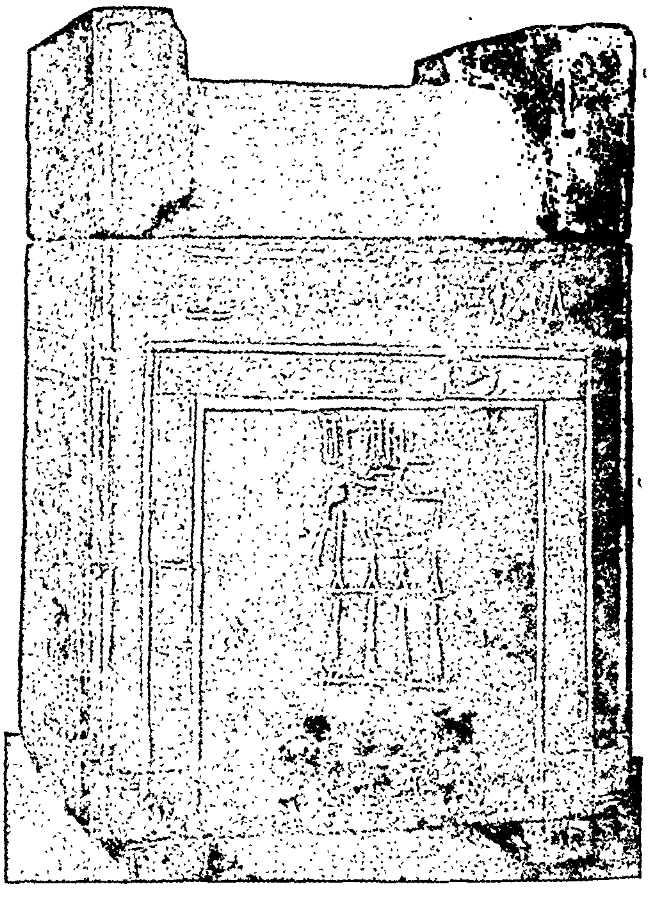

Fig. 2.—Stone case in which medicine chest was found in queen's tomb.

EGYPTIAN AND MOSAIC MEDICINE.

Moses, in whatever period he existed, was known to have resided at the court of Pharaoh, and to have received his collegiate education among the wise men of Egypt, and in the same school in which the Ebers Papyrus was written. The immortal Ebers, in his "Aegypton und die Bücher Moses," Berlin, 1868, has already shown the existing similarity of the Bible and Egyptian writings.

---

[10] Ap. eund, p. 54 c.

Biblical botany no doubt originated with the Egyptians and found its way into the Mosaic writings. The same source led to the knowledge of the plant world and the most remarkable phenomena of plant life.

We find the Bible not poor in the designation of different plants and their various parts. In the very beginning (Gen. i, 11) we read: "And God said: Let the earth bring forth grass, the herb yielding seed and the fruit tree yielding fruit after his kind," etc.

Biblical Medicine.—Moses, who evidently borrowed from the writings and teachings of the Egyptians, gives us in his "five books" information of their anatomic knowledge. In the narrative of the twin birth of Esau and Jacob it is related that the latter grasped the former's heel (Genesis xxv, 26); and in the description of Jacob wrestling with the angel it is remarked that the angel touched Jacob's hollow of the thigh, and put it out of joint (Genesis xxxii, 25); and in the same chapter, verse 32, the "sinew that shrank" is spoken of.

In Exodus (xxviii, xxix) the heart, brow, shoulder, breast, lobe of the ear, hand, finger and thumb are mentioned. In Exodus (xxix, 17) dissection is mentioned, "and thou shalt cut the ram into sections"; some of the visceral portions are also mentioned, such as inwards, caul, liver, fat kidneys; skin also occurs. In Deuteronomy (xxxii, 10) the apple of the eye is mentioned, the lids (Ps. xi, 4), and eyes (Exodus xxi, 24); bones (Gen. ii, 23), and sinews (Gen. xxx, 32); teeth (Gen. xlix, 12); palate, temple (Cant. ii, 3; vi, 7). In Job (xvi, 13) we read of pouring out his "gall" on the ground.

The Bible tells us of physicians (Gen. l, 2): "And Joseph commanded his servants, the physicians, to embalm his father." Isaiah (iii, 7) mentions particularly a healer: "I will not be a healer." We also find that the Jewish prophets, as well as the Egyptian prophets, practiced the art of healing. This may be seen from the narration of a man of God who restored the paralyzed hand of King Jeroboam (I Kings, xiii, 4-6). Elijah brought to life a child, apparently dead (I Kings xvii, 17-22); and his disciple, Elisha (II Kings iv, 18-20, 34-35) performed similar miraculous cures. Isaiah (II Kings xx, 7) cured King Hezekiah of an inflammation by applying a plaster made of figs.

The Bible likewise mentions surgeons and surgery of wounds and injuries in different parts of the body, caused by various weapons—sword, arrow, hammer, etc. (II Sam. ii, 23; iii, 27; iv, 6; xviii, 14; xx, 10; Num. xxv, 8; Judges iii, 21; v, 24; I Kings, xxii, 34; II Chron. xxxv, 23; and many other places). Inflammation and abscesses (Deut. xxviii, 25, 27) are also mentioned. Wounds were treated by the application of wine or oil, bandages or sutures (Isa. i, 6; Jer. viii, 22; xlvi, ii; li, 8; Deut. xxviii, 27). Gangrene and putrid discharges (Ps. xxxviii, 6; Prov. xii, 4; xiv, 30; II Macc. ix, 9) are spoken of.

It is also evident that Moses acquired a knowledge of chemistry from the Egyptians. As Boerhaave aptly remarks, the fact that Moses knew how to reduce gold to powder so as to render it miscible with water, and by this means potable, shows he had acquired a knowledge of chemistry only to be attained by the highest masters of science and art.

The fact that apothecaries (*Rakha*) are mentioned in the books of Moses (Exodus xxx, 25-35, "after the art of the apothecary"; Exodus xxxvii, 29, "according to the work of an apothecary"; Ecclesiastes x, 1, "the ointment of the apothecary;" II Chronicles xvi, 14, "prepared by the apothecaries' art"), and the compounded prescriptions in the Ebers Papyrus, furnish us evidence that a distinct class of apothecaries existed among the ancient Egyptians, who were cultivated pharmacists.

Certainly more competency was required of the ancient pharmacists than of those of our day, for the former had to make their own pills, extracts, infusions, etc., as we can find no proof that there existed manufacturing chemists. Their prescriptions were composed of many ingredients and many remedies. Of the 108 columns in the Ebers Papyrus, seven were devoted to tænia alone.

There can hardly be a doubt that the Ebers Papyrus existed prior to the exodus of the Israelites, and that the Biblical medicine embodied in the so-called Torna shebacsab (written law) had its origin in the valley of the Nile.

Post-Biblical Medicine.—Beginning with the post-Biblical history of medicine, we have the script, which was discovered 623 B. C., but which may have been handed down by oral tradition for many centuries before, and which is called Torha shebalpæ, or oral law. In this work is found a book on medicine (saphar raphout), containing classifications of plants, trees, etc., and their habitations.

We also know that another Egyptian monarch, Nakhepsus of Sais, in the seventh century B. C., wrote on medicine. It is said that he was the first to observe the wonderful virtues of green jasper, which when engraved with a dragon with rays, and hung around the neck, was considered a cure for digestive disturbances.

The employment of numerous drugs in Egypt has been mentioned by both sacred and profane writers; and the medicinal properties of many herbs which grow in the deserts, particularly between the Nile and the Red Sea, are still known to Arabs, though their application has been but imperfectly recorded and preserved.

Homer[11] speaks of the great number of medicinal plants and herbs produced in Egypt, some of which grew naturally, while others were cultivated.

The fame of the Egyptian physicians was spread throughout the ancient world. Homer described them as the "sons of Pæon, skillful above all men." In the third book of Herodotus is the following passage: "Cyrus sent to Amasis (500 B. C.) and bade him for an oculist—the best in the whole land of Egypt." Darius also sent hither for a body physician, and in the time of Tiberius and Nero, Egyptian physicians regularly came to Rome, usually to heal skin diseases. The science of medicine among this ancient people was in the hands of specialists, who were called *Snu.* Homer, and later Herodotus (ii, 37) tell us that there was a specialist for each single disease, and what records we now possess of the Egyptians after thousands of years of continued destruction corroborate the statement of the latter when he says that Egypt swarmed with physicians. They concealed their medical knowledge under the most mysterious formulas, and therefore used a writing or language not understood by the laity. The Latin prescriptions of our modern physicians appear to be an echo of the secret doings of our ancient colleagues.

The subdivision of the medical profession which prevailed among the Egyptians must have had a tendency, in some respects, to advance medical knowledge by specializing it. If we review the contents of the Papyrus, we can not but admit that the Egyptian physicians were well advanced in ophthalmology. The collection of Hippocrates, edited 4,000 years later, did not contain more don, Leyden, Turin, Bulak and Leipsic, the last being the Ebers Papyrus, which, because of its rich contents, the distinctness of its script and its completeness is foremost in importance.

---

[11] Odyss., vol. iv, pp. 228-230.

In order to fill the vacuum between Ebers Papyrus and the writings of Hippocrates, we must not overlook the inscription on one of the "Mastabas," or tombs of Egyptian grandees, which surround the pyramids of Sakkareh, that of Sekhet-enankh, chief physician of the Pharaoh Sahura of the fifth dynasty, 3533 B. C. It describes how he healed the king's nostrils, for which his majesty wishes him "a long life in holiness"; and the compilation of medical works assigned by tradition to one of the most ancient kings, Teta, the successor of Menes of the first dynasty. Manetho,[10] the Egyptian priest and historian, tells us that this king wrote treatises on anatomy and surgery and performed surgical operations with flint flakes. About 3300 B. C., during the reign of Cheops, the builder of the great pyramid, a medical papyrus containing anatomy was found by a priest in a temple. We also know that the Egyptians practiced embalming for over 5000 years B. C., and their process surely necessitated a knowledge of anatomy. There can be no doubt, therefore, that this ancient people knew the structure of the body, and without that knowledge they could not have understood even the symptoms of the different maladies enumerated in the Ebers papyrus.

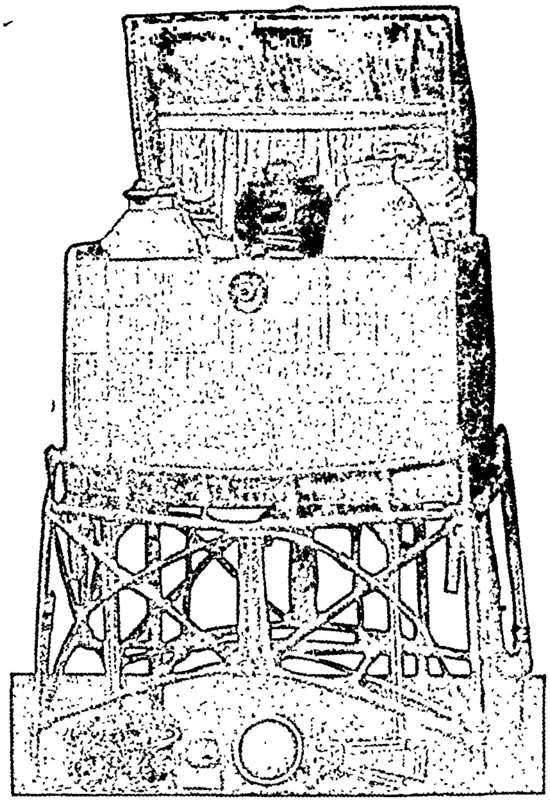

Fig. 1.—A domestic medicine chest of an Egyptian queen.

Pliny (XIX, 5) tells us that the Egyptians examined the bodies after death, to ascertain the nature of the diseases of which they died. There may have been a prejudice against it, perhaps, just the same as there is to-day, but the Egyptians did not shrink from human dissection, consequently the study of anatomy was a matter of course. However, they may not have attained the degree that we might expect in comparison with their other medical knowledge.

Another relic of Egyptian medicine is the domestic medicine chest (Fig. 1) of the wife of the Pharaoh Mentu'hotep of the eleventh dynasty, 2500 B. C. It contains six cases, one of alabaster and five of serpentine, with dried remnants of drugs, two spoons, a piece of linen cloth and some roots, enclosed in a basket of straw-work. It was found in the queen's tomb (Fig. 2).

Beginning with the earliest chronology on the existence of Moses, or his five books in the Bible, and considering the doubtful authority and the most accepted authority, namely, Josephus, who believed that Moses wrote Exodus about 1985 B. C., and Bunsen, who stated that Moses died 1523 B. C., we observe a difference of 462 years in the dates assigned to the life of Moses, hence between the two authorities we naturally come to the conclusion that the five books of Moses must have been written between 1985 B. C., and 1523 B. C. Hence, as between the oldest and the latest parts of the Ebers Papyrus lies a vast space of time, over 3,000 years, the whole dating from various epochs between 4688 B. C. and 1552 B. C., it appears reasonable to conclude that Moses knew Egyptian medicine. Medical literature was considered sacred, and therefore was carefully guarded from the profane eyes of the laity, and was only open to members of the priest class and their matriculants.

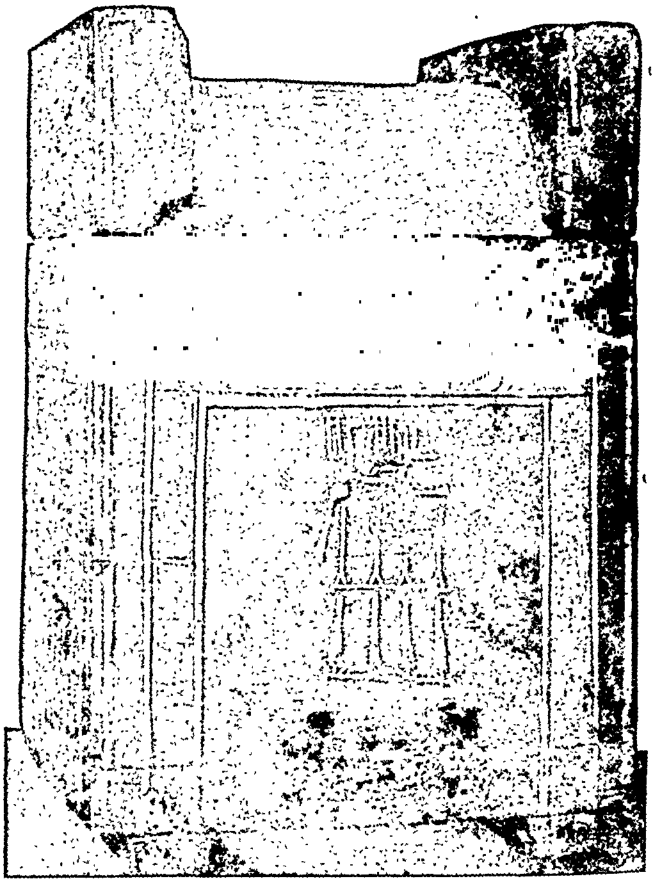

Fig. 2.—Stone case in which medicine chest was found in queen's tomb.

EGYPTIAN AND MOSAIC MEDICINE.

Moses, in whatever period he existed, was known to have resided at the court of Pharaoh, and to have received his collegiate education among the wise men of Egypt, and in the same school in which the Ebers Papyrus was written. The immortal Ebers, in his "Aegypton und die Bücher Moses," Berlin, 1868, has already shown the existing similarity of the Bible and Egyptian writings.

---

[10] Ap. eund, p. 54 c.

Biblical botany no doubt originated with the Egyptians and found its way into the Mosaic writings. The same source led to the knowledge of the plant world and the most remarkable phenomena of plant life.

We find the Bible not poor in the designation of different plants and their various parts. In the very beginning (Gen. i, 11) we read: "And God said: Let the earth bring forth grass, the herb yielding seed and the fruit tree yielding fruit after his kind," etc.

Biblical Medicine.—Moses, who evidently borrowed from the writings and teachings of the Egyptians, gives us in his "five books" information of their anatomic knowledge. In the narrative of the twin birth of Esau and Jacob it is related that the latter grasped the former's heel (Genesis xxv, 26); and in the description of Jacob wrestling with the angel it is remarked that the angel touched Jacob's hollow of the thigh, and put it out of joint (Genesis xxxii, 25); and in the same chapter, verse 32, the "sinew that shrank" is spoken of.

In Exodus (xxviii, xxix) the heart, brow, shoulder, breast, lobe of the ear, hand, finger and thumb are mentioned. In Exodus (xxix, 17) dissection is mentioned, "and thou shalt cut the ram into sections"; some of the visceral portions are also mentioned, such as inwards, caul, liver, fat kidneys; skin also occurs. In Deuteronomy (xxxii, 10) the apple of the eye is mentioned, the lids (Ps. xi, 4), and eyes (Exodus xxi, 24); bones (Gen. ii, 23), and sinews (Gen. xxx, 32); teeth (Gen. xlix, 12); palate, temple (Cant. ii, 3; vi, 7). In Job (xvi, 13) we read of pouring out his "gall" on the ground.

The Bible tells us of physicians (Gen. l, 2): "And Joseph commanded his servants, the physicians, to embalm his father." Isaiah (iii, 7) mentions particularly a healer: "I will not be a healer." We also find that the Jewish prophets, as well as the Egyptian prophets, practiced the art of healing. This may be seen from the narration of a man of God who restored the paralyzed hand of King Jeroboam (I Kings, xiii, 4-6). Elijah brought to life a child, apparently dead (I Kings xvii, 17-22); and his disciple, Elisha (II Kings iv, 18-20, 34-35) performed similar miraculous cures. Isaiah (II Kings xx, 7) cured King Hezekiah of an inflammation by applying a plaster made of figs.

The Bible likewise mentions surgeons and surgery of wounds and injuries in different parts of the body, caused by various weapons—sword, arrow, hammer, etc. (II Sam. ii, 23; iii, 27; iv, 6; xviii, 14; xx, 10; Num. xxv, 8; Judges iii, 21; v, 24; I Kings, xxii, 34; II Chron. xxxv, 23; and many other places). Inflammation and abscesses (Deut. xxviii, 25, 27) are also mentioned. Wounds were treated by the application of wine or oil, bandages or sutures (Isa. i, 6; Jer. viii, 22; xlvi, ii; li, 8; Deut. xxviii, 27). Gangrene and putrid discharges (Ps. xxxviii, 6; Prov. xii, 4; xiv, 30; II Macc. ix, 9) are spoken of.

It is also evident that Moses acquired a knowledge of chemistry from the Egyptians. As Boerhaave aptly remarks, the fact that Moses knew how to reduce gold to powder so as to render it miscible with water, and by this means potable, shows he had acquired a knowledge of chemistry only to be attained by the highest masters of science and art.

The fact that apothecaries (*Rakha*) are mentioned in the books of Moses (Exodus xxx, 25-35, "after the art of the apothecary"; Exodus xxxvii, 29, "according to the work of an apothecary"; Ecclesiastes x, 1, "the ointment of the apothecary;" II Chronicles xvi, 14, "prepared by the apothecaries' art"), and the compounded prescriptions in the Ebers Papyrus, furnish us evidence that a distinct class of apothecaries existed among the ancient Egyptians, who were cultivated pharmacists.

Certainly more competency was required of the ancient pharmacists than of those of our day, for the former had to make their own pills, extracts, infusions, etc., as we can find no proof that there existed manufacturing chemists. Their prescriptions were composed of many ingredients and many remedies. Of the 108 columns in the Ebers Papyrus, seven were devoted to tænia alone.

There can hardly be a doubt that the Ebers Papyrus existed prior to the exodus of the Israelites, and that the Biblical medicine embodied in the so-called Torna shebacsab (written law) had its origin in the valley of the Nile.

Post-Biblical Medicine.—Beginning with the post-Biblical history of medicine, we have the script, which was discovered 623 B. C., but which may have been handed down by oral tradition for many centuries before, and which is called Torha shebalpæ, or oral law. In this work is found a book on medicine (saphar raphout), containing classifications of plants, trees, etc., and their habitations.

We also know that another Egyptian monarch, Nakhepsus of Sais, in the seventh century B. C., wrote on medicine. It is said that he was the first to observe the wonderful virtues of green jasper, which when engraved with a dragon with rays, and hung around the neck, was considered a cure for digestive disturbances.

The employment of numerous drugs in Egypt has been mentioned by both sacred and profane writers; and the medicinal properties of many herbs which grow in the deserts, particularly between the Nile and the Red Sea, are still known to Arabs, though their application has been but imperfectly recorded and preserved.

Homer[11] speaks of the great number of medicinal plants and herbs produced in Egypt, some of which grew naturally, while others were cultivated.

The fame of the Egyptian physicians was spread throughout the ancient world. Homer described them as the "sons of Pæon, skillful above all men." In the third book of Herodotus is the following passage: "Cyrus sent to Amasis (500 B. C.) and bade him for an oculist—the best in the whole land of Egypt." Darius also sent hither for a body physician, and in the time of Tiberius and Nero, Egyptian physicians regularly came to Rome, usually to heal skin diseases. The science of medicine among this ancient people was in the hands of specialists, who were called *Snu.* Homer, and later Herodotus (ii, 37) tell us that there was a specialist for each single disease, and what records we now possess of the Egyptians after thousands of years of continued destruction corroborate the statement of the latter when he says that Egypt swarmed with physicians. They concealed their medical knowledge under the most mysterious formulas, and therefore used a writing or language not understood by the laity. The Latin prescriptions of our modern physicians appear to be an echo of the secret doings of our ancient colleagues.

The subdivision of the medical profession which prevailed among the Egyptians must have had a tendency, in some respects, to advance medical knowledge by specializing it. If we review the contents of the Papyrus, we can not but admit that the Egyptian physicians were well advanced in ophthalmology. The collection of Hippocrates, edited 4,000 years later, did not contain more eye diseases, but they were more clearly and more agreeably described. The number of diseases mentiond in the Ebers Papyrus, as well as the profusion of medicines prescribed, is a source of wonder to modern physicians. The ancient Egyptians must have been experienced diagnosticians. All physicians, however, were required by law to employ the prescribed remedies, and in no case to resort to others unless, as Aristotle (iii, 10) states, the regularly authorized prescriptions proved unavailing. Any transgression of this rule of practice, if followed by the death of the patient, was a capital offense. This may have been but a nominal law, or one, as Finlayson says,[12] "held in reserve to check abuses, for the complicated formulas and large choice of alternate remedies indicated in the Ebers Papyrus would seem to show that no great weight was attached to strict adherence to special methods, deviation from which was fatal."

---

[11] Odyss., vol. iv, pp. 228-230.

Up to a recent period our knowledge of Egyptian medicine was gathered solely from scattered passages from great writers. Praxagoras (though from Cos, the town where Hippocrates was born, and where the temple of Esculapius was built, lived in Egypt), of whom Galen speaks as the greatest symptomologist and diagnostician, and quotes his treatment for acute diseases, and especially gymnastics, was the teacher of Herophilus (400 B. C.), the first anatomist who made postmortems on cadavers. The former went to Egypt for his medical learning, and established a school for Greek physicians; the latter went for the same purpose and founded a system of pathology.

We have a continuous history of Egypt to the extent of about 5,000 years B. C., and a prehistoric account of 2,000 and a continuous culture known to us to cover about 2,000 years more, hence our continuous knowledge probably extends back to about 9000 B. C.

The Ebers Papyrus, therefore, opens a new era for the history of medicine and pharmacology. The work discloses an astonishing knowledge of a great variety of remedies, and shows that four or five thousand years before Christ there were learned men in Egypt who could make intelligent observations of disease, combine complicated prescriptions and use them with judgment. It is hardly possible to exaggerate the literary, scientific and historical importance of this wonderful papyrus, the most complete compendium of Egyptian medical science that is left to us, and we must acknowledge the fact that the copy of the Ebers Papyrus is the genesis of medicine.

TRANSLATION.

My sole purpose in translating the "Papyrus Ebers" into the English language is identical with that of the illustrious Ebers himself, namely, to bring out the origin and to cultivate the prehistoric knowledge of medicine, and to show that there existed in ancient Egypt nearly 7,000 years ago a civilization in which medical knowledge was in a high state of cultivation and in which the foundation of our present system of medicine was established. A careful study of this papyrus will convince the student that the medicine of to-day is essentially the medicine of the ancient Egyptians. Certainly it was in a crude state and on the same footing as our wearing apparel, both in custom and in fashion. Man has always covered his nakedness from the day that Adam ate of the apple. Garments have developed from the leaf covering to our present style of dress. In our latest advancement of civilization we have doffed the turban and donned the hat; we have cast aside the chiton and have clad ourselves in the frock; we have dispensed with the kilt and adopted trousers; we have thrust aside the sandal and have replaced it with the shoe. A similar evolution has taken place in medicine. New garbs adorn anatomy, physiology, pathology, botany, chemistry and materia medica in general, but the fundamental principles of curing disease still remain the same. Even the various methods in the practice of medicine have not changed. From all historical accounts and from the contents and language of this papyrus, we have evidence that the ancient Egyptians had three different classes of physicians—the regulars, the priest physicians and the conjurers, just the same as we have to-day. Our advancement consists merely in a greater variety. We have regulars, irregulars, faith healers and many others, too numerous to mention.

In my translation I have added commentary notes, the aim of which is to establish the fact that medicine up to, and from, the time of Hippocrates until the present day has been built on the foundation of that of the ancient Egyptians.

It was with great hesitancy that I entered on this very difficult task, by reason of a real distrust of my own ability. My knowledge of Egyptology is but superficial, and yet I have been greatly encouraged by medical men in various parts of the world, to whom I had communicated my intention. On their advice, therefore, I venture to offer this work, not only to fill a hiatus in our medical history, but to bring forth for the first time in the English language the ancient treasure of medical knowledge, namely, "Papyrus Ebers," translated from the original, utilizing the labors of Ebers, Stern, Brugsch, Chasbas, Dümchen, Ermann, Lüring, Lieblein, Joachim, von Oefele, Hirschberg, Scheuthauer, Schäfer, Proksch, Lange, Piehl and many other renowned Egyptologists.

The assistance of the above-named scientists, whose labors cover a period of over thirty years, and their criticisms of one another have enabled me to produce probably the best translation in a modern tongue. I have borrowed from these eminent minds not as a plagiarist, but as a kleptomaniac, who steals for the benefit of others. In no place have I failed to acknowledge the theft by a footnote; therefore, I can only appeal for mercy to those who are always ready to engineer some method of criticism, be it just or unjust. I have spared no pains to render the translation as accurate as possible. In a work involving such an infinity of details and interpretations, doubtful to even more scholarly Egyptologists, it would be unreasonable to expect that no errors or misinterpretations would occur.

While the outline of my work is as crude as that of a pioneer, I trust it will serve the labors of others who are more accomplished.

I now come to that which is to me the most painful part of my duty; that is, to inform you that the immortal Ebers had worked on a translation for a period of twenty-five years. His death, however, unhappily cut short his labors. On opening his last will and testament it was found that in case of death the manuscript was to be burned; accordingly, his will was carried out.

In conclusion, gentlemen, allow me to acknowledge my sincere gratitude to Baron von Oefele, the greatest living medical Egyptologist and ancient medical historian, for his consent to review and to correct my translation of the "Papyrus Ebers" before its publication. I also wish to express my thanks to my daughter, Edith, who for seven long years has labored by my side, inspired not merely by the devotion of filial love, but also by the same interest and purpose as that of her father, namely, to cultivate medical history and to elevate the standing of the humane and noble profession of medicine.

THE WATER SUPPLY IN SHIPS FROM ITS BEGINNING TO THE PRESENT TIME.*

HENRY G. BEYER, M.D.
Medical Instructor U. S. Navy.
WASHINGTON, D. C.

(Concluded from page 1852.)

CHANGES IN OUR PRESENT METHOD OF STORING AND DISTRIBUTING WATER, RECENTLY PROPOSED.

Certain well-marked sanitary defects inherent in our present methods of storing and distributing water on shipboard must have been noticed by every thoughtful naval surgeon, no matter how brief his experience at sea. These defects concern the water tanks, the pipe connections and the scuttlebutt. To begin with, one fundamental difficulty about the water tanks, located as they are, near the bottom of the ship, is, that it is at times almost impossible for a man in the hold to distinguish the one containing merely feed or other utility water from the one containing distilled water for drinking. Since much might depend on this under certain circumstances, measures should be taken to prevent such a mistake from occurring. A radical remedy has recently been suggested by Couteaud and Girard,[12] who recommended the establishment of two separate holds, one in the forward part, the other in the after part of the ship; one for utility water, the other for distilled water. Again, the danger of drinking water becoming mixed with utility water on board ship is not alone dependent on a mistake in the tanks; it may likewise be traced to faulty pipe connections, as was shown in a recent experience of mine in this instance, the drinking water, as well as the salt water, were circulating in one system of pipes, separated from one another only by certain cut-out valves. The consequence was that neither sweet water nor salt water could be drawn without taking part of the other into the bargain. Since the quantity of salt water thus added to the sweet water in both kitchen and pantry was very large; and since, moreover, the salt water, in this instance, was in fact undiluted sewage drawn from the harbor of one of our navy yards, it could not help being quickly discovered and remedied. One such experience ought to suffice to show the great necessity for the widest possible separation of both tank and pipes carrying utility water from those carrying distilled water. Each should circulate in its own separate system of pipes and be independent of cut-out valves.

Dr. Le Méhauté, in the article referred to above, has placed the whole subject in an entirely new light before the naval medical profession. He has clearly pointed out present defects and suggested means to remove them. The objects to be aimed at are: (1) The protection of the water from impurities that may originate in the present reservoirs and pipes themselves; (2) its protection from the impurities liable to get into it from the outside; (3) the providing of a method for the disinfection of tanks and pipes.

The measures which Le Méhauté suggests to meet these various demands are as follows: (1) Simplify the pipe system and remove all unnecessary parts of it; (2) hermetically seal the entire system and make the water circulate in a closed system of vessels; (3) protect the metallic sides of the system against attacks by water; (4) provide a method to disinfect the system which shall be simple, efficacious and always at hand; (5) adopt steam under pressure as a means for disinfecting the pipes.

It certainly would seem obvious that by reducing the length of the distributing pipes and by removing all unnecessary parts of the system the danger from inside impurities can be materially decreased. Since, perhaps, the greatest danger from impurities lies outside the system, the hermetic sealing of the entire system, from the tanks to the fountains, would almost suggest itself. The dangers lurking around the water tanks from outside contaminations must have suggested themselves to every inspecting officer who has seen them and appreciated them but once. The changes recommended by Le Méhauté as regards the construction of these tanks, in view of these dangers, would seem to be most opportune and very much to the point. They are: (1) Place the manholes on the side instead of at the top of the tanks; (2) provide every tank with a metallic aspirating tube permanently fixed to one of its sides and closed outside by a screw plug; (3) ventilate the tanks through an **L** shaped pipe, provided at the lower outside end with a tampon of absorbent cotton to filter the air; (4) keep the upper surface free, closed and unencumbered; (5) slightly incline the bottom surface to allow of the accumulation of any deposit of possible iron rust and provide a purging spigot at the most dependent part of the bottom of the tank for an easy removal of the solid impurities collected there. Another suggestion deserving attention in this connection is the one made by Couteaud and Girard.[13] These authors would reduce the large number of small tanks, at present in use, into a small number—say three or four—of large reservoirs or cisterns, containing up to 14 or 15 tons of water each and place them between the two protective decks. They are also in favor of placing the manhole on the side instead of on top.

These suggestions are sound, and every naval sanitarian will endorse them without much hesitation. The hermetic sealing of the pipe system would naturally make disinfection sometime a necessity and hence provision must be made for it. Since it would involve a great deal of difficulty to take the system apart for such a purpose, the method of steam disinfection suggested is the one practically applicable method. For the purpose of disinfecting the tanks, the soldering lamp is no doubt the best means. Whether it is that the pipes are choked up mechanically with iron rust or coal dust, or, whether infected water has passed through them, the method of steam disinfection is equally applicable.

Thus, it will be seen, that hygiene has become exacting. It cannot rest content with half-way measures because these do not meet her ends. It is due to half-way measures that some much useless time and money-wasting experimenting has been done in the past, as we have seen, without producing the desired results. It is also evident that the hermetic sealing of the whole water circulating system and the modifications in the construction of the tanks, as recommended by Le Méhauté, must insure a faultless product inside of them.

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[12] L'Hygiene dans la Marine de Guerre, Paris, 1905.

* Read in the Section on Hygiene and Sanitary Science of the

Having thus far obtained a perfect water inside of our tanks and pipes, we must aim to get it inside the sailors' stomachs in the same uncontaminated condition. To this end, the scuttlebutt system is the next detail to be improved.

DISTRIBUTION OF WATER.

The problem involved in the process of conducting drinking water from the tanks to the individual in an absolutely pure and uncontaminated condition has never until recently been approached courageously and seriously. It is held by some that the greatest and gravest danger lies in the manner of distributing water on board ships; that infectious diseases are more often transmitted and epidemics spread and kept alive through the common drinking cup than in other ways. Even the individual drinking cup appears to have proved a failure and has been abandoned where it was used formerly, because, if the men did not lose it, they would loan it to one another and thus defeat its very object.

To-day, men in most of our ships get their drinking water from what is called the "scuttlebutt." This is a wooden barrel-shaped vessel, somewhat broader below than above, provided with a brass spiggot near the bottom and varying in size with the size of the ship and in number with the number of men on board. On large ships several of these are placed in convenient places. A common drinking cup of some metal is attached to the spigot by a small chain and this the men use to get their water. At one time the interior of the scuttlebutt was divided into an upper and lower carbon, spongy iron, etc., and the lower compartment containing filtered water. At one time, a long stationary metallic tube was inserted, the lower end being immersed in the water, the upper bent into a right angle and terminating in a mouthpiece through which the men were obliged to suck up their water. This method was in general use in the French navy from 1819 to 1850, when the order was passed for mouthpieces to be made of glass; these breaking too easily, the mouthpieces were ordered to be made of iron, of lead and still others of wood. None of these ever proved entirely satisfactory. In 1809 Lefèvre says of the custom of using the mouthpieces, then in general use: "Besides the repugnance which such a method must inspire of being obliged to take into your mouth a nozzle which was a moment before in that of another, does not this practice open the way for the transmission of contagious diseases from one man to another?" And indeed Fonessagrives had already then recommended that these mouthpieces be made detachable and that they be immersed in water before being used. Bressanin likewise recommended immersion in water. Others recommended a detachable mouthpiece, one that could be increased in the suction pipe of the scuttlebutt and was attached to each person by a cord so as to prevent the wearer from either leaving it attached to the mouthpiece or losing it, or even lending it to another. According to Couteaud and Girard, the scuttlebutt in use in France is made of iron, lined with rubber; it has a spiggot to which the common metallic drinking cup is attached with a chain. They recommended the substitution of a *biberon a bec* for the cup. These *becs*, after being used, to be put into a basin where a jet of hot water may disinfect them. The particular mouthpiece they refer to is made of iron and was designed by chief mechanic Estève of the *Iena*. According to Belli,[14] Dr. Carbone has actually succeeded in getting the individual cannula adopted on board the *Pisani*. On this ship every man is provided with a mouthpiece of bone which he attaches to the scuttlebutt whenever he wishes to quench his thirst. An arrangement of three small elevations around the opening of the pipe at the scuttlebutt obliges the man to use his own mouthpiece to get water. While Belli is convinced that this method is theoretically a good one, in practice, it has shown to have several disadvantages.

The cannulas become clogged easily from dirt in the pockets of the men; they also can be passed from one to another, just as the individual drinking cup. Belli raised the question as to the necessity of all men being obliged to get their water by suction. Indeed, since the necessity for so great an economy, as was practiced in former years, on long voyages, has entirely made way for a more liberal distribution of water, this question is very much in order. Belli wants these suction arrangements abolished and thrown on the scrap heap. In the U. S. Navy this arrangement has never been popular, but the common drinking cup is in general use.

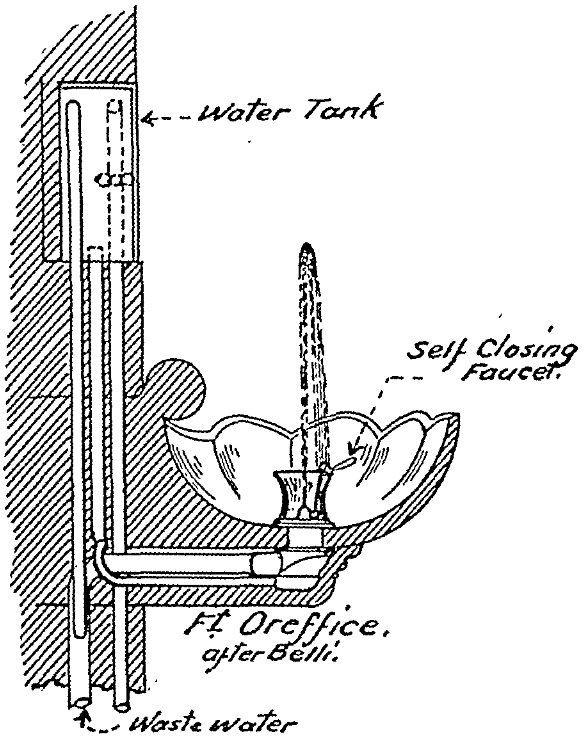

Fig. 7.—Showing water tank and self-closing faucet.

Within recent years, water fountains have been recommended for use on board ship to take the place of the old scuttlebutt. Since, with these fountains alone, the question of the common or individual drinking cups remains the same, only special fountains can come up for consideration. The need for a hygienic distribution of water on board ship is very much the same as it is in the case of public schools and other public places. In 1894 an Italian engineer named Torelli exhibited a fountain at the National Exposition at Milan. This fountain is in actual use in the public schools of Milan. It consists of several little spouts fed by water under pressure and arranged in a circle inside of a basin. Each orifice is protected by a funnel, 15 cm. in height, perforated at the bottom and not permitting the drinker to touch the orifice with his mouth or with his fingers. In drinking the boys simply lean over the spout and allow the water to flow into their mouths. A similar fountain has been constructed by Dr. F. Accorimboni for the normal schools at Foligno in which the jet projects horizontally (Fig. 8) and in which the nozzle is protected from contact with the drinker's lips by a metallic screen.

---

[14] M'Belli, Innovazioni igieniche sulle nave da guerra—ann. di mod. navale. Annovifasc, vol. III, 1900.

The fountains of Milan and of Foligno, however, are without a regulator and the water flows constantly. Such a regulator is found on the fountains designed by the engineer, Oreffice, and introduced by him into all the public schools of Padova and Venice (Figs. 7 and 9). The little jet is provided with a spring lock which the drinker opens at will and which closes automatically, thus avoiding unnecessary waste of water. The little short orifice is protected by a conical cup, the upper margin of which is armed with a metallic fringe which does not permit the drinker to approach it with his lips. The slight overflow rinses the walls of the cup and passes directly into the waste pipe.

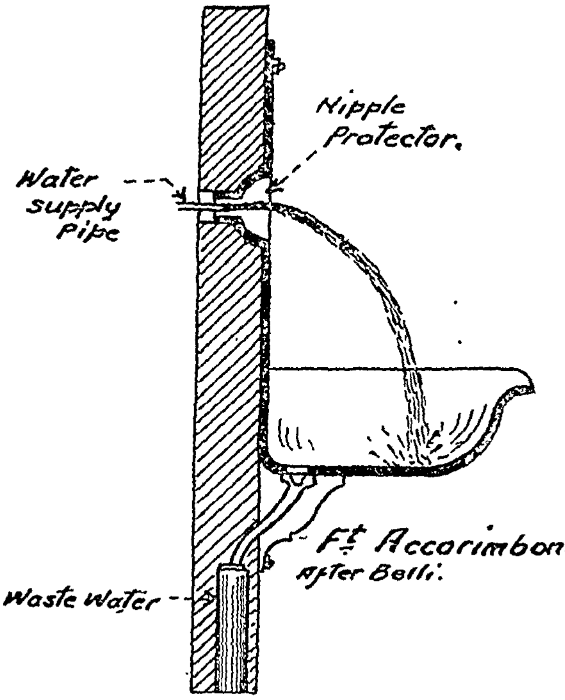

Fig. 8.—Drinking fountain designed by Accorimboni.

Belli suggests that the advantages of these two fountains combined might, perhaps, be adapted to ship's use. A proper combination, no doubt, would do away with the risk of infection and at the same time insure the economical use of drinking water.

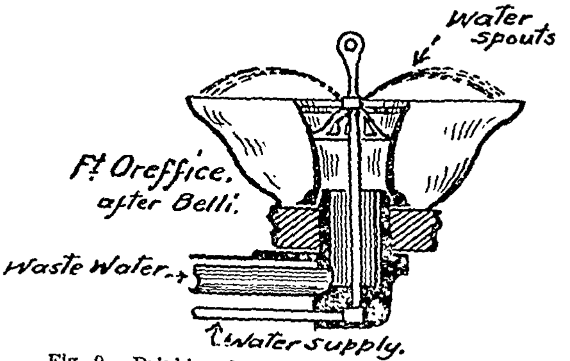

Fig. 9.—Drinking fountain devised by Oreffice.

It certainly has become highly desirable that the old-fashioned scuttlebutt with the common drinking cup as now in common use in the navy be displaced by some form of reservoir of distribution, answering to the present requirements of personal hygiene. Since it has become recognized beyond question that the common drinking cup is one of the worst means of spreading contagious diseases on board ship, efforts are now being made in almost all the navies of the civilized world to do away with it.

Le Méhauté is very strongly in favor of the individual pipette. The fountain which he prefers is shown in the adjoining Figure 10, which shows the pipettes in place. He proposes that a number of these pipettes, duly sterilized, be placed in a vessel near the fountain where any man may take one, put it in place, drink and then put it into another vessel, where it remains until again sterilized by boiling in soda.

DISTILLED OR STERILIZED WATER.

An important sanitary question has only recently been raised by Le Méhauté[15] of the French navy. The question asked by Dr. Le Méhauté is whether it shall be distilled or sterilized water that is used on vessels of the navy or whether both be used under a given set of circumstances and conditions. This question is important and destined to receive considerable attention by naval sanitarians in the near future.

It is, of course, of fundamental importance to hygiene to furnish such a water as shall in composition correspond as nearly as possible to a natural, unpolluted drinking water. There is no longer any doubt about the fact that distilled water for ship's use is no such absolute necessity as it was in years gone by. Since the wooden casks have been generally done away with and a cement lining for iron tanks was adopted, water put into them no longer putrefies, but keeps sweet for an almost indefinite length of time. Most of the large passenger steamers have, for many years past, taken their water supply directly from the water mains of the port in which they happened to be and filled their tanks and double bottoms with it. Steamers rarely resort to distillation, though legally obliged to carry distillers on board, on account of the short duration of the voyages they make. Although vessels of war invariably carry distillers, they, too, fill up with sweet water before leaving port and distill only on long voyages and after their sweet water supply has begun to give out.

---

[15] Arch. de Medicine Navale, Nos. 9 and 10, 1904.

It must be admitted, perhaps, that a sterilized water is more nearly a natural water than is distilled water and as such deserves the preference. The general desire on the part of all civilized governments at present is becoming more and more evident, namely, to make every effort to surround their men-at-arms, whether ashore or afloat, with the most sanitary conditions possible. Already the French war department has begun to introduce water sterilizers in large numbers into the soldiers' barracks, and naval stations are being supplied with them. Le Méhauté strongly urges the introduction of sterilizers into the navy, arguing as follows: "Certain vessels of the navy are destined to remain for a long time on foreign stations and others are obliged to make long cruises, visiting places in which the supply of water is not always good. For such ships distilled water is a necessity. Many other ships, however, stay on the home station or visit places in which the water supply leaves nothing to be desired and where, consequently, these ships may supply themselves with all the water they need. Such water, to eliminate the last possible chance of doubt, need only be sterilized." Méhauté, moreover, says of sterilized water that it bears the same relation to distilled water as does natural food to unnatural or canned food and that it would be both unwise, uneconomical and unhygienic to drink distilled water or to eat canned food when the more natural products were available.

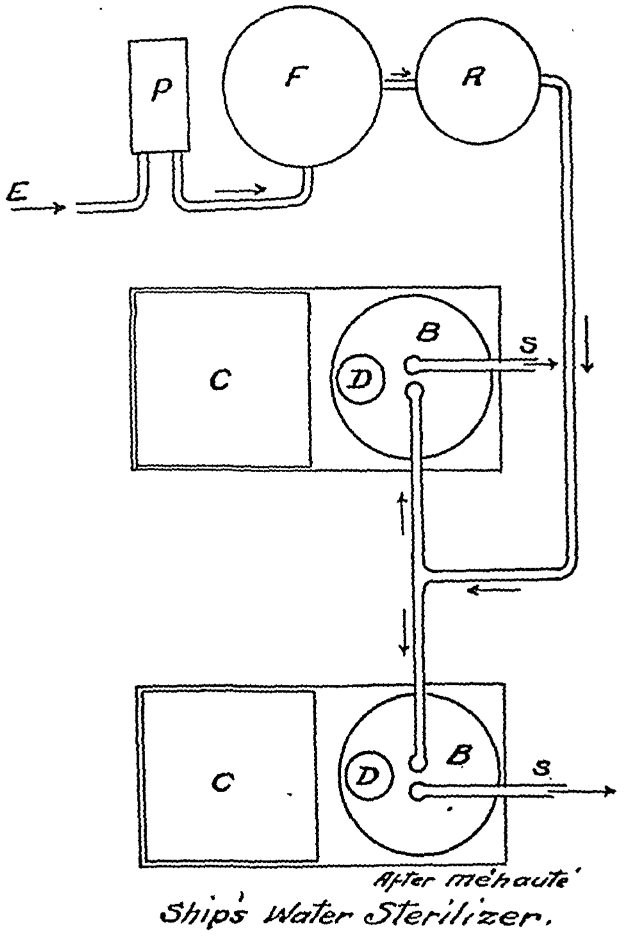

Fig. 11.—Showing the principles of the sterilizer which Méhauté proposes for adoption. P, water reservoir; F, pressure filter; B, where hot water gives off heat to incoming cold water; C, the heater; D, apparatus where precipitates are removed; E, where water enters; S, where sterilized water makes its exit.

The principal reasons for substituting sterilized for distilled water, in which we must all agree, are three: (1) Distilled water is expensive and sterilized water is not. (2) Distilled water is not a natural water; sterilized water answers more nearly to that description than does distilled water and should, therefore get the preference. (3) Distilled water is often offensive; sterilized water is never offensive and always safe, being germ free. Certain objections have, however, been raised against the introduction of sterilizers by Couteaud and Girard,[12] the principal ones of which are the following: (1) The inconvenience of having on board two systems of water purification, since distilling can not be done away with and must remain the last resource; (2) the sterilizers have not worked well either in France or China, where they were used during the campaign of 1900-1901, on account of the hard Chinese waters (Jacquemin). It is also not inconceivable that the different parts attached to the sterilizer might become sources of infection.

According to Le Méhauté, the sterilizer Salvator can be made to produce one ton of water at 7 centimes in French money. Professor Vaillard, at Val de Grace, has calculated that two kg. of coal furnished 2,000 liters of sterilized water, while the quantity of distilled water cost 7 francs the ton. According to Couteaud and Girard, Chief Engineer Danoy has made some calculations on the Iena that would not seem quite so favorable. He calculates that one kg. of coal burned in the furnace would sterilize $\frac{5176 \text{ cal.}}{170 \text{ cal.}} = 30$ kg. of water. This same kg. of coal would produce 5 kg. of distilled water; that is, 1/6 the quantity of sterilized water. The actual daily expenditure in sweet water on board the ship was 9,000 liters, of which 800 liters were distilled water used for drinking. These last cost the state $\frac{800}{5} = 160$ kg. of coal. If it was necessary to sterilize all the 9,000 liters of sweet water, the cost in coal would amount to $\frac{9000}{5 \times 6} = 333$ kg., or just twice the amount required to distill the 800 liters of drinking water.

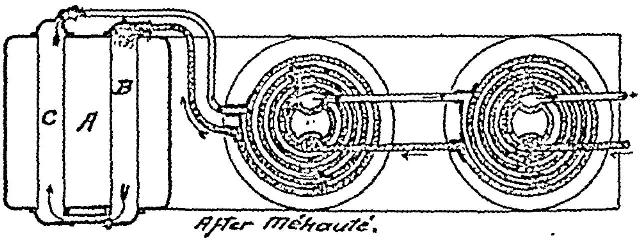

Fig. 12.—This represents schematically the circulation of the water in the recuperator.

The adjoining diagram (Fig. 11) is intended to show the principles of the sterilizer which Le Méhauté proposes for adoption. In this scheme P represents the water reservoir, F the pressure filter, R the accumulator, B where the hot water gives off its heat to the incoming cold water, C is the heater, D is an apparatus in which the precipitates are removed, E shows where the water enters, and S where the sterilized water makes its exit.

Providing a double sterilizer is installed, each one working independently of the other, no check in the process need be apprehended. The heat required for sterilizing comes in the form of steam from one of the main boilers.

The only part of this sterilizer needing special description is the recuperator (B), in which the sterilized hot water parts with its heat, transporting it to the incoming current of cold water. This piece of apparatus it is intended for the adjoining diagram to illustrate and make intelligent.

Figure 12 represents schematically the circulation of the water in the recuperator. The white spiral shows the course which the water takes that is cold and to be sterilized; the shaded spiral contains the warm sterilized product. In order to give back to the sterilized water its refreshing taste, a very ingenious apparatus has been employed.

This apparatus is made of spirally arranged metallic plates, inclosing spaces about 26 cm. high and 5 mm. broad and absolutely tight. These spaces are divided into two separate and distinct channels: The one for the cold and the other for the hot water. The cold water takes the direction toward the heater, the sterilized water passes on the inverse sense; the one goes from the periphery to the center, the other from the center to the periphery. In this circuit the heat is exchanged.

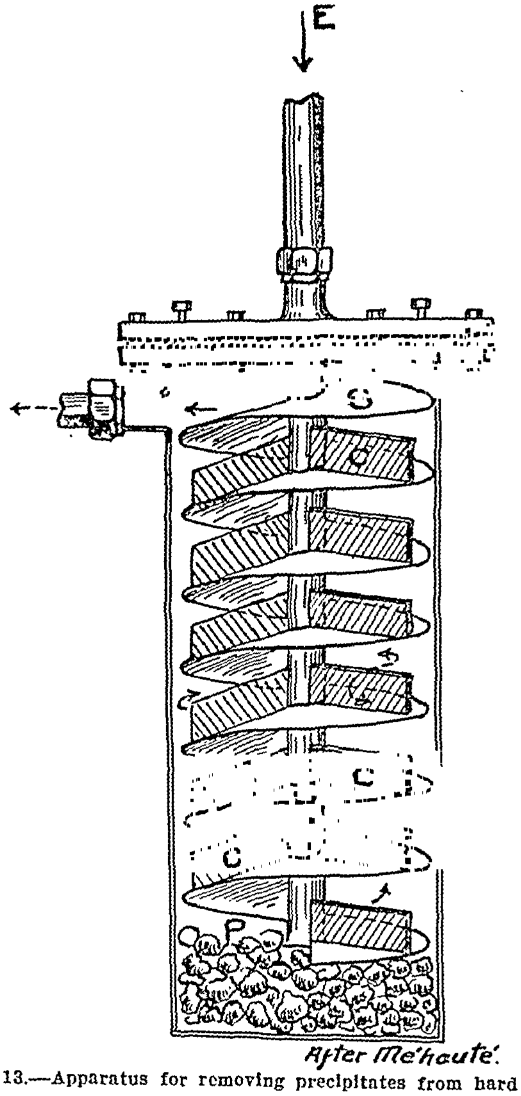

Fig. 13.—Apparatus for removing precipitates from hard water.

When the sterilizer Salvator was tried on board the *Caledonian* and the *Couronne* it did not give entire satisfaction. Preliminary trials demonstrated the necessity of a filter and an attachment in some form for the removal of the precipitates formed during the boiling of an especially hard water. Both these desiderata having been met, the sterilizer works without a fault.

The more [illegible] of these two additional pieces being [illegible]," a brief description will be of interest.

This apparatus (Fig. 13) is intended to remove the earthy precipitates from hard water that formed during boiling. The water enters at E, passes through the central tube to the bottom of the apparatus, where it enters a pile of rough stones, it then gradually rises along the spiral S which carries the vertical plates C intended to retard its progress, and thus compelling it to leave its suspended solid particles behind. The cleaning of the apparatus is very simple. It suffices to remove the cover, to take out the screw-like central part and clean it with a solution of HCL in water, 1/50.

With these two improvements attached, the French ministry of marine has made new trials which have proved unusually satisfactory, according to Le Méhauté, and the report made to him by Dr. Plagneux, the medical director at the depot at Cherbourg. According to these, the sterilizer has worked already for six months without needing any cleaning.

The preceding summary of the water question on board ships contains all the more important features of hygienic interest to-day. The proposed substitution of sterilized for distilled water may seem new to some of us, but it is a question which can not be evaded and which must be answered squarely in the near future.

With such a system as has been proposed by Le Méhauté, we might even question altogether the necessity of sterilization, except perhaps when the water in the tanks or in the pipes or fountains had from some cause been subject to infection or was under suspicion of being infected. With tanks lined with cement, closed on top and connected with a closed and clean system of pipes, pouring their water into a fountain provided with individual and sterilized pipettes, the chances of any possible infection of the water, as well as its transmission from man to man, seems infinitesimal and reduced to a negligible minimum. It is, however, just this negligible minimum which an exacting and consistent hygienist must try to eliminate.

There is no subject within the whole range of naval hygiene in regard to which the prospects for the near future appear as bright and as promising; none concerning which we are as near a satisfactory solution as with the water question on shipboard. At the same time there is no other problem the study of which would lend itself so well for illustrating the slow but sure and progressive influence of hygiene and sanitation on human affairs, near and remote, as does the story of the gradual evolution of the water question on shipboard from the earliest to the present time.

DISCUSSION.

Dr. Denslow Lewis, Chicago, referred to the fact that distilled water may become distasteful, and at times even repulsive and somewhat injurious. He asked if attempts have been made to dissolve any of the normal constituents of water in distilled water with a view of obviating any unfavorable effect on the gastric mucous membrane.

Dr. H. G. Beyer replied that Fonssagrives, the famous French naval surgeon, recommended the addition of small quantities of salines years ago, but the practice did not become popular. Water that is distilled from salt water under ship's conditions is not an absolutely pure product. Chlorin and a few other things were found present constantly at the time Dr. Beyer was engaged in making daily analyses for months.

Dr. C. E. Woodruff, United States Army, said that in hospitals he had tried the use of salts in distilled water. There is great trouble in getting good water at a number of places, but the use of salts has never been tried to improve the general water supply of the post; it is entirely too big a problem for that. But for patients Dr. Woodruff thinks it is easy to put up salts to imitate any mineral water, making it, say, by the gallon. This will obviate all gastric irritation, but it is entirely too big a problem for an entire post.

Dr. L. M. Powers, Los Angeles, Cal., remarked that a great deal of the trouble with distilled water is due to its not being entirely aërated rather than to its want of mineral contents. He thinks aëration very important.

Dr. H. G. Beyer agreed that aëration has a great deal to do with it, but he declared that, strange to say, the modern idea seems to be that these air injectors which were in use formerly, have been entirely eliminated. Some say they are dangerous; they want them eliminated because they introduce millions of germs and other things, which make a filter necessary, and which it is the modern aim to do away with. Another reason for doing away with the aërator is that the water may be depended on to aërate itself, and this is actually the case. Unless the filter is carefully watched it will become a source of infection rather than a means of the prevention of infection. Dr. Beyer said that the water aërator and cooler which he mentioned is a very excellent device for small ships in which the tank capacity is not sufficient to keep the water long enough in the tanks to cool it after being distilled, and if the distilled product is properly protected from impurities by strainers, a distilled water can be produced that is free from dust. The fact remains, however, that the water ought to be aërated to make it palatable.

Dr. M. L. Price, Baltimore, referred to aëration by sterilized air. There is a surgical instrument used to sterilize air, which seems to be very practicable, and he wondered if it could be used to sterilize air for aëration of water.

Dr. L. M. Powers, Los Angeles, Cal., referred to a milk evaporating plant in which the air is forced through a pipe into the vat and trays of cotton batting are placed in the stack so that the air has to pass through the cotton and is thereby filtered. Dr. Powers knew of a fish commissioner who used an atomizer so as to mix air with the water to a great advantage. He thought that a method could be devised for sterilizing the air before using it to aërate the water and thereby supply the necessary oxygen without infection.

Dr. H. G. Beyer said that the object of admitting the air into milk during the process of evaporation is more to facilitate evaporation than to aërate it. In distilling water, if air is allowed to pass through the water while it is evaporating in the distiller twice the amount can be produced, and a similar result follows aëration of milk.

PSYCHOSIS OF MORPHINISM.*

T. D. CROTHERS, M.D.
Superintendent Walnut Lodge Hospital.
HARTFORD, CONN.

All writers have mentioned the general defective conception of truth and the relation of right and wrong which appears to be a prominent symptom in all persons who use morphia. It is difficult to understand whether this is a veritable paralysis of the higher reasoning centers or a defect of the senses by which distorted conceptions of facts are not recognized. In all probability both conditions exist, and what is termed moral paralysis is a symptom of some condition of degeneration which is common to these persons in the later stages. This symptom practically describes a defect in the reasoning faculties and inability to recognize the value of truth and honesty, also a disposition to conceal the facts and distort them, no matter what their relation may be.

I shall attempt to group some of these symptoms which may be termed the psychosis of morphinism. The first is a palsy of the consciousness of right and wrong and the inability or indisposition to discriminate between the real and the false. The second is an intense anxiety and zeal to explain and to give reasons for a certain conduct and an explanation of why this or that was done. Third, there is noted some local irritation and disorder of the language centers in which thought is expressed in the most extravagant and impulsive way; or in the most secretive, hesitating and doubtful words. A fourth psychosis is a morbid impulse to deceive, to take advantage, or a keen delight in swindling, misrepresenting, and acting out new characters while under the influence of morphia. This condition was first described by me some years ago, and has been confirmed in some marked criminal cases since then.

The first grouping, called moral palsies, is an impulse to live under a mask for the purpose of concealing their exact condition, or taking advantage of circumstances that appear to be favorable to some personal interest. Many of these persons show this paralysis only in connection with the use of the drug. On all other matters they are frank, honest and exceptionally truthful, but in regard to the use of opium and its alkaloids they practice the worst kind of deception and unreasoning prevarication. They often show extraordinary childishness in denying the use of the drug and manifest indignation on being suspected. Sometimes this denial is followed by intense zeal and anxiety to explain the conduct and motives. In many instances great ingenuity will be apparent to trace it to some particular cause, generally to objective things. This I call the second symptom.

In the first the drug taker is pleased stoutly to deny the implication that he is using drugs. In the second his denials are less emphatic, but his explanations of motives and conduct are so faulty and strained as to convict himself. Often these explanations refer to acts that are associated with the use of opium and not with matters outside. Some patients will be scrupulously honest and exact on matters of observation and in opinions concerning the surroundings, but in securing and using opium they are falsifiers of the boldest class.

There seems to be in many instances a growth and an increase of this particular psychosis, which begins first with mild denials of the use of the drug, then going on to shrewd explanations and reasons, and finally culminating in profound deception and general demoralization on every topic and subject relating to themselves and environment. Generally, long before this stage is reached, changes of appearance, eccentric conduct and indifference to the opinions of others with general degeneration become prominent. The stage of profuse explanation is sometimes very childish and lacking in skill to conceal the real condition. In others it is bold and ingenious, with unusual cunning and apparent frankness. Running through this is a vein of intense egotism and pleasure to convince others of great honesty and an apparent good judgment and sagacity to discriminate as to the value of certain impressions. Thus, in one case, a concealed morphin taker, who detected the slightest suspicion in other persons concerning his conduct, would drop everything and take infinite pains and care to disarm this suspicion.

A clergyman, who had reached this stage of morphinism that attracted attention, spent a large part of his time in explaining to his friends that he was innocent and was misjudged. Each new explanation, by its intensity and minuteness, failed in a degree and required other efforts and explanation. This man was able to go on with his professional work in the pulpit without comment, but eventually resigned and disappeared. Often this stage is associated with a general failure of vigor and previous mentality. He is duller, sleeps in the daytime, is awake at night, blunders in business affairs, makes mistakes in correspondence, forgets proper names and neglects to pay bills, together with the great variety of marked psychical changes. In business he may be more acute and accurate in collecting bills and contracting debts, or the opposite. A certain irregularity of thought and conduct and a suspicion of others are all typical of his condition.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In a third psychosis, marked from the beginning or only seen in the later stages, is paralysis of the language centers. The manner of expression is changed. Whether loquacious or taciturn, the words that are used to express the thoughts are strange and unusual Often they consist of expletives and forcible exclamations, low figures of speech or low slang words uttered in a reckless way, or the opposite, viz., formal, precise, symbolic expressions that seem rather to conceal than express the feelings of the author. This psychosis is frequently seen in literature, particularly in the variable styles noted in a single article or book, suggesting at once the influence of morphia on the language centers.

A slangy, dogmatic, jerking expression followed by a stiff, pedantic style indicates two stages of morphinism. At the beginning the effects of the drug obscures the consciousness of the value of language and the meaning of the terms used. Later when this wears off, conservatism and secretiveness come on, and the language changes; misty, high-sounding words are used to express the feelings. A great variety of peculiarities in speaking and writing and the sudden change of topics, with apparent inability to keep the mind concentrated on one subject, is very significant of this form of addiction.

DeQuincy had language exaltation, or delirium, but when under the influence of opium he was able to write good English, and careful students of his writings will discover lapses and changes which are clearly due to this cause. One author has described these as defects of consciousness. Another has called them disorders of the sensation, such as hyperesthesia or anesthesia.

There is a marked mental change associated with these symptoms. With it is noted an exaggerated egotism and confidence in the patient's ability to understand the relation of events and shape his conduct so that the real condition may be concealed. In some instances the secret use of morphia exalts some of the senses and depresses others. This may account for some of the confusion states which follow. Probably taste, touch and smell are more or less affected, and the impressions from these disordered senses have much to do in perverting the reason and lowering the consciousness. In the latter stages these conditions are apparent.

A fourth psychosis may be practically called a delirium and morbid impulse to deceive, to take advantage of others, acting out a new character, enjoying the pleasure of taking advantage of others' credulity and the ability to conceal and misrepresent.

It has been noted for a long time that kleptomania was so common that many chronic cases were unable to resist the opportunity to take things. In the police courts it has been noted that some of the shrewdest swindlers, pickpockets and confidence men are addicted to the use of morphia. Under the influence of morphia they exhibit an acuteness of intellect and audacity never seen in the ordinary law breaker, but when the morphia is withdrawn they display the greatest weakness and childishness of manner and conduct.

An example of this kind was that of a man very highly educated and of good social standing who became addicted to the use of morphia and entered on a career of swindling and deception. It seemed to be his greatest delight to go about following the crowds at watering places, hotels and the steamers, making the acquaintances of strangers and securing loans on fraudulent checks, brass jewelry and false diamonds. He had no confederates and never mingled with anybody of the same class. To his friends he represented that he was in the brokerage business, making and placing loans. He used morphia constantly, and after long journeys would return home and remain concealed for days. He carried with him various disguises and changes of clothing, and had a number of cheap crystals set in elegant rings and pins. These he would leave as security for loans made him by strangers. He had numerous letters of introduction and bill heads of prominent firms which he used on all occasions to raise money. His manner was that of great frankness and honesty, and his evident earnestness made friends wherever he went. At times he would solicit loans, giving worthless checks and references or watches and jewelry as security. Then he would pay bills for clothes, jewelry, books or board at the hotel by forged checks, receiving in return balances of money. He would call on leading business men on various plausible pretenses and secure their signatures, which he would copy so accurately on checks that the maker was unable to detect whether they were his own or forged ones. Several times he was arrested, but his great honesty and earnestness of manner completely baffled all investigation. Finally he was detected, deprived of his morphia, and the real condition discovered.

Another man of this class was a sanitarium swindler. and for many years he visited different institutions and was apparently treated for this addiction, but in every instance swindled the proprietor in fraudulent checks and loans on false securities, then disappeared. In a short time he would enter another institution, pay in advance, secure the confidence of the manager, draw back most of the money and deposit checks as securities, then have a telegraphic call to visit a dying mother. This same man traveled on the ocean steamers for two years, making many victims, assuming all sorts of disguises, but finally was arrested and convicted.

A third example was the case of a man who came under my observation charged with larceny. I found it impossible to keep him from the use of morphia. On the trial he was acquitted, but consented to remain with me. I found that he was an excellent type of the Hyde and Jekyll class while under the influence of morphia. His intelligence seemed to be of the most acute character. He reasoned quickly and accurately, was an excellent judge of human nature and adroit to take advantage of every opportunity. If accused of sinister motives, he manifested the honesty and frankness of a saint and could make his accusers regret exceedingly that they misunderstood him. When arrested by a detective he quickly convinced him that he had made a mistake, and his injured innocence seemed so clear that the detective was overwhelmed. He left me to make a visit to a neighboring city, and soon after was arrested in the act of receiving cash for a forged note. He sent for me to confirm his statement that he could not have had such a note and that he was only a patient under my care. So shrewdly did he defend himself that the judge released him.

I found that the criminal instinct to forge notes, sell gold bric-a-brac and do other most adroit pieces of swindling was a veritable delirium and one which he enjoyed when under the influence of morphia. The drug gave him a certain amount of confidence in himself and made him fearless of any results. Of course, he was a moral paralytic. The morphia rendered him more in-sensible to every consideration of duty of right and wrong, and he was able to judge of the weakness of others and take advantage of their circumstances in the most skillful way. He received a yearly annuity from his father's estate, was independent and not engaged in any business. His swindling operations were undertaken as a pleasure, and any gains he received from them were always used to enlarge his sphere of acquaintance and help him enjoy the pleasure of his avocation. He was a total abstainer and used morphia regularly every day, and was finally arrested, sent to state's prison and died a year later from consumption.

No doubt all such persons are moral degenerates at the beginning before the drug is taken. The use of the drug gives a certain courage and shrewdness which for the time being is an exact representation of the real condition; therefore, it is accompanied with evidence of honesty and frankness and disarms all critics. Of course, a career of crime of this class is of short duration, because the use of the drug can not be kept down to the minimum amount. The stimulating stage grows shorter and shorter and the narcotic stage longer.

One of these criminal morphinists was registered in three different hotels in a certain city. At each place he appeared in a different disguise and could so thoroughly conceal his identity and voice that he was not recognized. In each hotel he swindled the proprietor and several of the guests, and then went away without being discovered. Later he tried the same thing in another city, but for some reason his morphia failed to help him out and he was discovered. This psychosis is fortunately not a common one, but it exists and is recognized among detectives more frequently than elsewhere. A physician who belonged to this class for many years has done much to destroy the good will and confidence in the profession of a certain city. He was continually the storm center of slander, dishonest practices, public libels and other thoroughly disreputable acts. His death and the complete subsidence of all discontent and conflict showed that he was the cause of all the deception and intrigue.

The moral paralysis and ethical failures of morphinists show lesions and defects of the higher centers of the brain which undoubtedly may either be inherited or acquired. A study of a number of persons suffering from this form of addiction shows that both the psychical and the physical suffer alike. We have paid great attention to the latter, but the former has received little or no study.

The gross changes seen in loss of pride and degeneration of personal appearance and sharp denials of the use of the drug are common, but the failure of the higher mentality to recognize duty and obligation to others is not studied. This contribution is along these lines. It aims merely to outline a field that is largely neglected, the study of which will enable us to apply therapeutic measures with far more exactness than ever.

A summary of what I wish to make clear may be stated as follows: The psychosis or psychical symptoms common to morphinism are, first, palsy of the consciousness of right and wrong and inability and indisposition to discriminate the ethical principles or responsibility and obligation; second, a delirious stage of profuse explanation and efforts to conceal and explain the reasons for his acts and conduct; third, a special exaltation or depression of the language centers, with a change in the manner of expression and the use of words; fourth, a veritable insanity to deceive, to misrepresent and to take advantage of the credulity of others, not for any purposes of gain, but for the satisfaction of being able to defraud and mislead, also to act in different characters and to elude the efforts of persons who would discover the condition.

DISCUSSION.

Dr. John Punton, Kansas City, Mo., said that the psychopathic features of the morphin psychosis are factors that should be of interest to all because of the medicolegal aspects of the subject. There are two features in reference to this that makes it all the more interesting to the practitioner. One is the ethical and the other is the legal side of the question. Some time ago a man went to Dr. Punton's office and stated that he was taking three grains of morphin daily, and that as a result he thought he was losing his reasoning power. Dr. Punton asked his occupation, and the man said that he was a train dispatcher. Dr. Punton wondered whether or not the patient was a responsible man for such a position. Ethically speaking, Dr. Punton has no right to divulge secrets given him in confidence, but he asked a leading lawyer what would be the probable outcome of the case if he should divulge such a professional secret and be sued for it. The lawyer told him that legally he would be held responsible. Only a short time since the *British Medical Journal* reported a similar case, and the newspapers commented on it and declared that under such circumstances the physician's duty to humanity was greater than to his patients. Soon after this patient's visit to Dr. Punton several serious accidents occurred on the railroad, and he has wondered whether the morphin did not have something to do with their occurrence.

Dr. G. R. Clark, Dearborn, Mich., asked Dr. Crothers if he had ever thought of placing those cases that were due to morphinism alongside of the cases of minor epilepsy and studying them together for six months at a time. Dr. Clark thinks that the same principles are at the bottom of each. The application of morphin in a case of epilepsy, plus the condition of the mind that always goes with that condition, would be very likely, Dr. Clark said, to create this condition of the mind.

Dr. T. D. Crothers said that without doubt in many of these cases there is evidence of an epileptoid taint. Why the continued sedation of the sensory centers should produce exaltation of reasoning and mental activities along certain lines is a phenomenon yet to be explained. The chief of one of the large detective offices of New York City told Dr. Crothers that the most dangerous and difficult cases to detect are criminals who used morphia. He referred to an instance of a man who for over four years traveled about the central cities of the country committing the same kind of crime and eluding the sharpest detectives. One day by accident the morphia was withdrawn, when his usual shrewdness failed and he was arrested. He had a large circle of friends, came from a good family and was highly educated. After a prolonged study it was decided that he was insane and he was permitted to go out under the care of his friends. Within a very short time he entered on another scheme of swindling by making contracts for lightning rods. His great skill consisted in ability to disguise himself and to go back over the same section of country, repeating his swindling schemes more successfully than ever. So long as the man was using morphia regularly he succeeded. These patients develop symptoms of insanity on removal of the drug and are placed in asylums. At present their recognition before this stage is reached is exceedingly difficult, and this study calls particular attention to a new class of psychoneuropaths who are criminals in acts unknown before.

The Great Black Plague.—Tuberculosis has been designated as "the great white plague"; with equal fitness venereal infection may be termed the great black plague", since it most aptly typifies "the pestilence that walketh in darkness." It infects unseen the social body; the vast mass of disease and misery thus engendered is concealed from observation so that there exists on the part of the public the densest ignorance respecting the ravages of an infection which, working in disguise and darkness, ramifies through every rank and order of society. At the present advanced stage of preventive medicine, it may be considered a reproach to sanitary science that this large and important class of diseases is absolutely neglected by the sanitary officials.—*Charities.*

COMPARISON OF THE QUICK AND THE SLOW METHODS OF THE TREATMENT OF MORPHINISM.*

A. J. PRESSEY, M.D.
CLEVELAND, OHIO.

Perhaps an explanation of the title of my paper would make it a little more clear. We will call all forms of treatment where the morphin is withdrawn at once, or where it is withdrawn within five or ten days, a quick method, and where the reduction is gradual and slow and extends over a period of several weeks or months we will term a slow method.

There has, within the past few years, been much advertising of quick cures for morphinism. Nearly every newspaper and magazine, and I am sorry to say some medical journals, contain one or more of these advertisements, and as it has been for the past dozen years my exclusive business to treat narcotic and alcoholic patients I have been much interested in searching for the best method of treatment. I have investigated several of the so-called three, five and ten-day cures. At none of these so-called quick cures do they do anything like what they advertise to do. The morphin is withdrawn within the specified time in some instances, to be sure, but the patient is far from being restored to his normal condition. Often they are in a very much worse condition than as though they had never taken any form of treatment. Hydrobromate of hyoscin is probably the remedy used in all these so-called quick cures. When the remedy is given to certain individuals in proper doses it apparently does remove the desire for morphin. The patient recovers from his hallucinations after five to ten days, soon begins to have an appetite and makes a fair recovery within a few weeks' time, but unfortunately this favorable ending is not the rule but the exception. It appears impossible to decide in advance which patients will tolerate the remedy and be so favorably influenced, and which may be permanently injured by the use of it. While I believe that death from the use of this drug is rare, mental derangement is common. I have known four patients where the mental equilibrium was not restored for several weeks and one patient that was in the insane asylum for six months, when she had somewhat improved and was discharged, but she has never yet returned to her normal condition, and it has been now more than three years since she was released from the asylum.

I have a patient under treatment at the time of writing this paper who was taken to an institution where they advertise to cure the morphin addiction in from 24 to 30 hours. Two weeks later his friends were notified by the physician in charge of the institution that the patient was insane and that he would probably die, and they had better take him home. He was brought to my place and two nurses were required to care for him for two weeks, and he had to be constantly watched for over a month. He was taking as much morphin when he came to me as he did before he took the hyoscin treatment. Now, at the end of two months, he is free of the morphin and seems in a fair way to regain his mental balance.

Dr. Crothers reports having tested the effects of hyoscin in several cases of morphinism and also in alcoholics and always with bad results. In each case delirium with hallucinations and delusions, came on after the second or third dose and continued from two to four weeks. In three instances the delirium lasted two months, and in one instance the mind did not recover and the patient was placed in an insane asylum, where he still remained two years later. Two alcoholics never recovered fully; while not drinking, they have become mild cases of dementia, with great prostration. He also reports a case of a physician who treated himself with large doses of hyoscin, who died suddenly, and that there were reasons for believing that this drug was the cause of death. Also another case treated by a physician with large doses of hyoscin and the morphin removed at once; the delirium lasted for two weeks, then suddenly terminated in coma and death.

Dr. Wagner reports several cases that he treated in the Cleveland City Hospital with hyoscin hydrobromate. He says that this treatment is not devoid of danger, and it is most important that no case be attempted without a special nurse day and night during active treatment, so that the patient is not alone for a minute during this period.

Dr. John Punton says that the treatment of morphinism with hyoscin is unsatisfactory and always contains an element of danger. A large percentage of patients treated after this method regain strength very slowly. One physician, with whom I am acquainted and who had been, up to the time of taking the hyoscin treatment, a strong, healthy man, was unable, after eight months, to attend to his professional duties, and I have known several similar cases.

This method of treatment is irrational and unsafe, and while, as I have previously said, there are some patients treated satisfactorily, the large majority are made only worse by the treatment. There has, as yet, been found no substitute or antidote for morphin, while with the gradual adaptive method we have a perfectly safe and sure form of treatment. Every patient not afflicted with some painful complicating malady who desires to be cured and will co-operate with the physician can be cured, and with very little discomfort. There is no class of patients who shrink from pain and discomfort as do morphinists. There is no other class that has so little fortitude. Why are not these unfortunates entitled to our consideration in making their recovery as painless as possible, just as much so as are surgical patients? There is no class that is more desirous to be relieved of their affliction than is the better element in the bondage of opium, remembering that among the many thousands of addicts there are very, very many of the best educated and most brilliant minds, many with a finely organized, highly developed nervous system, who have worked on a high tension, who have either through their own or some other person's indiscretion or carelessness become the slave of morphin. Others who have been unfortunate in having a long and painful illness, when it seemed almost impossible to endure the suffering, have been given the drug until they have not had the necessary will power to discontinue the morphin after they had recovered from such afflictions. These patients are entitled to our very best efforts to relieve them and with as little suffering as possible.

Thousands of persons are to-day enslaved with the morphin habit that would have taken treatment and become free of the addiction did they not have such a dread and horror of the suffering that they anticipate they must endure in being relieved of it.

There have been several forms of slow withdrawal advocated by different men, such as withdrawing a small fraction of the daily dose each day or withdrawing a certain amount every third or fourth day. Also the adaptive slow withdrawal.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

No patient can be kept anything like comfortable where a certain amount of his daily dose, or a certain part of a grain is withdrawn at a certain time or at fixed periods. Such a plan would assume that every day was the same, that is, that a person felt the same every day and there were no headaches, no neuralgias, no indigestion, and a thousand other causes that will produce extreme discomfort if the quantity of the drug is lessened at such times. Such a system will be necessarily more or less of a failure, unless the reduction is so very slow and is made to extend over a very much longer period than would be required by the adaptive plan. When the above plan is practiced there is sure to be so much discomfort, nervousness and nausea that there will be little or no physical improvement during the period of withdrawal, and consequently there will have to be a longer period of convalescence than as though the patient had been kept more comfortable by the adaptive plan and had been regaining health and strength during the entire time, as a large majority of patients will do.

The adaptive plan, as I practice it, I have described in papers previously read in this section, so that it is unnecessary to go into details. It may be well, however, to give the outlines of the plan of reduction. When the patient comes for treatment he is probably taking from two to four times as much morphin as he requires to keep him comfortable. This surplus may be withdrawn at once. He is also very likely taking one or more other drugs which may be discontinued at once. Perhaps it may require four or five days to find out just how much reduction can be made and still not make him too uncomfortable. We may have reduced the quantity too much and the dose have to be increased a little before we get him started just right. When the quantity has been found that will keep him almost comfortable from one dose time until the next, we make no change in this amount for three or four days, or until the patient is feeling very well, when another small reduction is made, so small that he will hardly be conscious of it. When we are again sure that the amount then being given is going to keep him comfortable, we make another small reduction. These are made only when the condition of the patient has so improved that the reduction will not make him too uncomfortable. Thus we continue the reduction until the quantity used is so small that it can be withdrawn without the patient's knowledge of it. This amount will seldom be more than 1/120 gr. In this way the large majority of morphinists can be kept more comfortable during the entire withdrawal period than while taking the drug themselves. Of course they will require a supportive and tonic treatment, combined with a nourishing diet, during the withdrawal period, which should be continued for some time afterward, depending on their condition.

One of the most difficult and important problems in the management of all cases of morphinism is after they are free of the morphin. Usually within three to ten days after the morphin has been entirely withdrawn they are feeling well and are anxious to get home, and in the large majority of cases it is impossible to get them to stay as long as they should to insure them as much as possible from relapse. For some time after the desire for the drug has been entirely removed there is an unstable, weak and eccentric mental condition, and during this time slight pain, trouble, grief or insomnia will often be sufficient cause to induce him to take a dose or two for temporary relief. Each dose weakens his resistance and the mania is quickly recontracted and is sure to happen if he allows himself to take the first dose. As much time as is necessary to secure a good physical and mental condition should be spent under the personal care of his physician. This is a case where if there is a mistake to be made it is profitable to make it on the safe side.

To recapitulate. The quick cure by hyoscin is irrational, unsafe and unsatisfactory. The diarrhea and vomiting which always occur after the sudden withdrawal of morphin, whether the hyoscin is given or not, which lasts from two to ten days, is very distressing, and the hallucinations, which last for an uncertain length of time are unpleasant, to say the least, and from which the patient may never recover. Relapses, I believe, are much more frequent and convalescence is usually greatly protracted.

The adaptive slow withdrawal is rational, safe and satisfactory. No diarrhea, vomiting, extreme nervousness or any of the severe symptoms shown with sudden withdrawal are ever produced. Convalescence is well advanced when the last small amount of morphin is withdrawn and nearly always rapidly completed. Relapses are much less likely to occur.

900 Fairmount Street.

DISCUSSION.

Dr. T. D. Crothers, Hartford, Conn., said that the subject of morphinism has a personal interest to every physician, because it is one of the most frequent addictions among active workers in the profession. From some studies which he made five years ago and which have since been fully confirmed, he is convinced that at least from 15 to 20 per cent. of physicians in active practice are victims of morphia and spirit-taking. Dr. Pressey's outline of the methods of treatment is very suggestive and demonstrates the efficiency of certain drugs when given with care and skill. Of course, there can be no specifics because the addiction is both a psychosis and a neurosis. All physicians have seen patients make a good recovery by use of hydropathic measures, and often persons recover from the exclusive use of some particular drug. It would not do to reason from this that all patients will recover by the same means. Each case is a law to itself and must be treated individually. There are no rules and no special classes of remedies which will apply to every patient.

Dr. H. G. Brainard, Los Angeles, declared that he was astounded at the statements made by Dr. Crothers and thinks that it is a sad reflection on the condition of the physician. Dr. Brainard said that he knows that in California there is no such proportion as 10 or even 5 per cent. of physicians who are victims of the morphin habit. He is sure that such conditions do not obtain in the profession throughout the country. He is sorry for the people of Connecticut if there is such a condition of affairs there.

Dr. A. J. Pressey said that the figures given by Dr. Crothers must be an estimate, as he does not understand how any one could get exact and reliable statistics on such a subject. Dr. Pressey does not think that there is any such proportion of morphin-users among physicians in any part of the country. More than half of the patients he treats are physicians, but that does not mean that half of all the morphin habitués are physicians. Too many physicians take this drug, but Dr. Pressey does not think there is quite 2 per cent., perhaps about 1 per cent. He does not know just how to get the exact figures.

Dr. T. D. Crothers, Hartford, Conn., said that the facts may be startling, but the evidence on which they are based fully sustains them. A general study of the habits of physicians in four of the largest cities of the country showed that from 10 to 15 per cent. were drug and spirit-takers. In one city a prominent daily paper made inquiries and concluded that at least 15 per cent. of all persons practicing medicine, including members of all the schools, were spirit and drug takers. In other cities the percentage has been estimated as high as 20. In one city over 11 per cent. of all physicians were known or reputed to be using drugs. Dr. Crothers said that he was not prepared to defend any exact statistical percentage as indicating the use of drugs and spirits among the profession, but the discussion of this subject for the past five years since his first study of the habits of 3,500 physicians which were made at that time have amply confirmed the original conclusions. One of the reasons for this is the failure of teachers in medical colleges to make prominent the dangers from both alcohol and opium. The young graduate seldom has any knowledge of the risks and perils from indiscriminate use of these drugs, and as a result many of the profession become victims at first secretly, then openly. This is one of the great personal dangers confronting the profession that should be studied and removed in the near future.

LAWS CONCERNING TEACHING HYGIENE.*

HELEN C. PUTNAM, M.D.

PROVIDENCE, R. I.

It has recently been my work in another medical society to compile and analyze our present laws relating to the teaching of hygiene, 45 state and 1 federal, all more or less elaborated. This time-consuming task was undertaken with ideas that I have been compelled to alter radically in the progress of the study. My anticipations were based on certain general—somewhat pessimistic—statements in lay, scientific and medical current literature; but the exact details now reported should be known to all physicians interested in preventive medicine.

It is not my intention to discuss this legislation further than to give the facts as they stand in the present laws.

The laws existing in 1903 (none have been altered since then) are published in the *Bulletin of the American Academy of Medicine*, April, 1904, as a preliminary report of the committee to investigate the teaching of hygiene in public schools. The details of all the statistics I shall give can be found in appendix A of the first installment of the committee's report published in the *Bulletin*, June, 1905.

It is well known that the initiator of public sentiment that has resulted in this legislation extending over all territory under our jurisdiction, was the Woman's Christian Temperance Union. Its immediate aim has been and is to have hygiene, in connection with instruction as to the nature and effects of alcohol, tobacco and other narcotics, taught on a scientific basis in public schools as thoroughly as is arithmetic or any other branch required by law. We find accordingly in all the laws the phrase "physiology and hygiene with special reference to the nature and effects of alcoholic drinks and other narcotics." There are several variations in this wording, the reasons for which it is not necessary to discuss at this time. The general interpretation of this clause is that physiology and hygiene shall be taught, including the special topic indicated.

The nine other chief details occur irregularly, most of them appearing first during the five years after the original law of 1882 in Vermont. Their *raison d'ètre* is that it seemed necessary to specify them in order to secure enforcement of the spirit of the law. Any physician who has had experience in our political methods can easily imagine the evasions these laws have met, in consequence chiefly of the opposition of one of the largest commercial interests, as well as from certain social influences; from the indifference or ignorance of many, and from teachers' lack of preparation for teaching science. Without going further into their history, let us now examine these nine legal specifications.

I. SPECIFICATIONS CONCERNING WHAT SCHOOLS SHALL TEACH HYGIENE.

The federal law specifies all public schools, including Indian and colored, in the territories and District of Columbia, and military and naval academies.

Twenty-three state laws specify "all public (common, free) schools."

Twenty-two specify "all schools supported wholly or in part by public money, or under state control," Illinois and New York adding all normal schools, teachers' training classes and institutes, and schools connected with reformatory institutions. Private schools having special charters are "under state control," but the law is not generally interpreted to include them. The law of Michigan, however, specifies all such schools, and the law of Massachusetts all private day schools except those solely for instruction in particular branches. Alabama specifies colleges; Indiana, Maryland, Minnesota, Ohio, Pennsylvania, Utah and Wyoming specify "all educational institutions" aided by state funds. This would include state universities, colleges and normal schools, certain institutions for study of special subjects, schools for defectives (blind, crippled, deaf mutes, feebleminded); schools for the neglected, destitute and incorrigible; schools in reformatory and penal institutions. I do not know how literally these seven laws are enforced. As a matter of fact, many of the 22 laws specifying simply "public schools" are interpreted to include normal, reformatory and some others.

This detail of the 46 laws differs little anywhere in actual intent, and the same is true of the next.

II. SPECIFICATION CONCERNING PREPARATION OF TEACHERS.

Fifteen states have only the general school law requiring examinations of teachers in all subjects ordered by law to be taught. Thirty specify examination in this branch as in others, Idaho excepting primary teachers; New Jersey, teachers of music, drawing, manual training, etc. The federal law does not mention examination of teachers in military and naval academies.

III. SPECIFICATIONS AS TO WHAT PUPILS IN THESE SCHOOLS SHALL RECEIVE INSTRUCTION.

Fourteen laws do not specify what pupils shall receive this instruction, and 23 specify "all pupils." California specifies all grades, in all classes, during entire school course; Connecticut, "above third grade and below high school;" Illinois and New York, "below second year of high school;" New Hampshire, "above primary grade;" South Carolina, "as far as practicable."

This detail as to teaching hygiene in primary and grammar grades is influenced by the fact that in round numbers out of five million pupils entering the lowest primary grade only one million go on to grammar grades, and only one-quarter of a million enter high school. Nineteen-twentieths of the pupils, and they of the poorer classes, would receive no instruction in hygiene if it were confined to high schools; sixteen-twentieths, none if it were confined to grammar schools.

IV. CONCERNING METHODS AND THOROUGHNESS OF INSTRUCTION.

Fourteen laws make no specification as to whether the instruction shall be oral or by text-book. Nine laws specify "text-books in the hands of pupils;" nine specify text-books for those able to read and oral instruction for those unable to read. California and Indiana require oral instruction only, but in fact have text-book instruction also.

---

* Read at the Thirty-third Annual Meeting of the American Public Health Association, Boston, September, 1905.

Twenty-five laws specify that instruction shall be as thorough as in any other branch required by law.

V. SPECIFICATIONS CONCERNING TEXT-BOOKS.

Only 14 laws out of the 46 make specifications concerning text-books.

Eight of these specify that they shall be approved by certain authorities; North Carolina, by the state text-book commission; New Hampshire, by the superintendent of public instruction; Nevada and Michigan, by the state board of education. Michigan's original law (1883) also included approval by the state board of health. This has been eliminated, and now Wisconsin is the only state requiring approval by its health officials. Minnesota requires approval of text-books on hygiene by the superintendent of public instruction and presidents of normal schools; Colorado, by the board of directors of the school district.

Four laws specify the minimum number of pages for instruction as to the nature and effects of alcoholic drinks and other narcotics.

Illinois, Michigan, New York and North Carolina require at least twenty pages in high school volumes, i. e., about one-twentieth of the volume. Below this grade Michigan and North Carolina require at least one-fourth of the volume; Illinois and New York, at least one-fifth, also adding that the pages in a separate chapter at the end of the book shall not be counted in this minimum. This provision was introduced, it is stated, to discourage the attempt to place in the schools old text-books to which a "temperance appendix" had been added to conform with the law requiring instruction in hygiene to include instruction in this special subject.

For the same reason the laws of 14 states specify that temperance instruction shall be given "in connection with the several divisions of the subject of physiology and hygiene;" i. e., that when studying the circulation, or the nervous or respiratory systems, pupils shall at that point be given instruction as to the effects of alcohol and other narcotics on each.

The laws of two states, New York and Illinois, specify that text-books shall be graded to the capacities of pupils of fourth year, intermediate, grammar and high schools.

VI. CONCERNING TIME TO BE USED FOR INSTRUCTION.

Three only out of 46 laws have specifications concerning length or minimum number of lessons in hygiene.

North Dakota has a minimum for oral instruction to those unable to read; at least 15 minutes daily, 4 days each week. This means an hour's weekly instruction in hygiene, including temperance, or a possible 24 hours yearly, the minimum school year being 6 months.

Illinois and New York, in the lowest three primary grades, require, respectively, three and two lessons each week, each year. If these are 15 minutes long they amount to 7½ hours and 5 hours oral instruction yearly for three years.

Illinois and New York require for text-book instruction four and three lessons weekly, respectively, for ten weeks each year from the fourth primary year to the second year in high school. Text-book lessons are usually 20 minutes. This amounts, therefore, to a minimum of 13½ and 10 hours yearly for six years; somewhat less for eleven-twelfths of the pupils who do not go through all grammar grades nor continue in high school.

We see from the above that the greatest requirement of any of the three laws is 24 hours minimum oral instruction yearly in physiology and hygiene, including temperance instruction; the other two states not exceeding a minimum 13½ hours for either oral or text-book teaching. The usual minimum time given to either reading and writing, geography or arithmetic is not far from 40 hours yearly. Therefore the laws of Illinois, New York and North Dakota can not justly be said to make undue claims for the subject of health. Certain other states in some schools give even more time to the subject.

VII. PUPILS' EXAMINATIONS IN HYGIENE.

Illinois, Iowa, Ohio and New York specify that pupils must pass the same tests in this as in other branches.

VIII. ENFORCEMENT OF LAWS.

A law, whether good or bad, is not infrequently futile because no one is interested in enforcing it or because, if interested, he has no means of overcoming the hostility or inefficiency of some official. Experience has proved the wisdom of providing a model law with three powers. The duty of enforcement must be definitely placed, the method of enforcement detailed, the penalty for non-enforcement indicated, and provision for complainants is sometimes made. In the legislation under discussion experience seemed to indicate that these provisions were sometimes desirable.

The duty of enforcing these laws is specifically assigned by 31 states, usually to certain local school authorities, occasionally adding the state superintendent or county board.

IX. REPORTS AND PENALTIES IN CASE OF NON-ENFORCEMENT.

Special reports from special sources are stipulated by 13 of these 31 states. They may be from teacher or other local official, or from any citizen or head of family, to some local or state official, or by the state superintendent in his annual report to the public. The report is frequently made to the official who pays out school money.

Penalties for non-enforcement of laws are specially mentioned by 19 of these states. They vary from removal of any guilty official from office, or revocation of teacher's certificate temporarily or otherwise, to loss of salary, or fines from $5 to $200 against any guilty official, or loss of all or part of state appropriation to school, city or district.

Delaware and Washington specify the officer of the law who shall recover the fines. Ohio and Washington specify what shall be done with said fines.

In states where no special mention is made of the enforcement of this law there is the general school law requiring teachers' compliance, subject to dismissal, etc.

I now beg to call your attention to the opportunities which these laws offer for the introduction of any alterations in the present teaching of hygiene. It will be observed that:

1. No law states what shall be taught as to the nature and effects of alcoholic drinks and narcotics; nor that total abstinence shall be taught.

2. No law prevents the teaching of hygiene through "domestic science," physical training, biology, medical inspection; nor from other viewpoints than physiologic, as economic, or sociologic. All these methods have be-

gun and are progressing along with our growing acquaintance with the subjects.

3. No law requires indorsement of text-books by the Woman's Christian Temperance Union.

4. Forty-two laws do not stipulate the space for temperance instruction in text-books on hygiene. Forty-three laws do not specify the number and length of lessons in hygiene (including temperance).

Or, in other words: These laws making the study of physiology and hygiene mandatory, as are other essentials of common education, provide opportunity to introduce text-books, methods, teachings, for any interested in hygiene who have the capacity to do it. They evidence in their details the intention that, so far as the law can secure it, the teaching of health shall be on a par with the teaching of mathematics, language, and physical environment. Certainly it ought to be. The laws are not hindrances, but proffer openings—more than proffer, they command the work to be done.

It is not the province of this paper to discuss the kind of work now doing, nor the kind of work that ought to be done, nor how a change, if desirable, can be effected; but whoever wishes to make a change must accomplish it not by expending vitality and time in altering laws, but by convincing school authorities that some other text-book or method will produce better results than those already in use.

A CASE OF BRAIN TUMOR.*

JULIUS GRINKER, M.D.
Professor Nervous and Mental Diseases, Chicago Post-Graduate Medical School; Assistant Professor in Clinical Neurology, Northwestern University Medical School; Neurologist to Cook County Hospital.
CHICAGO.

Patient.—M. M., a Lithuanian laborer, aged 28, entered Cook County Hospital March 14, 1905, and was assigned to the care of Dr. Kuh. The following April he came under my service and remained under my observation until April 28, when a transfer to the surgical side was recommended. Dr. Schroeder performed an operation May 4, 1905, and the patient died May 5, 1905.

History.—Family and personal history are negative and syphilis is denied. He states that his habits were always good and that he never sustained an injury. Three weeks previous to admission the patient began to complain of severe headaches, which were constant and generalized. At about the same time spells of vomiting appeared which seemed to have no relation to the gastric functions. A feeling of nausea always accompanied these vomiting spells, but sometimes there was nausea without vomiting. Somewhat later in the course of the disease attacks of vertigo came on whenever the patient attempted to stand or walk. Then progressive generalized weakness of the entire muscular apparatus became a marked feature. The before mentioned symptoms soon inhibited any kind of work and compelled the patient to lie in bed most of the time.

Examination.—He is a man of medium height and weight, with well-developed muscles, but staggers in attempts at walking. The face appears slightly asymmetrical, though no paralysis or paresis can be detected when the muscles are at rest. The skin is somewhat muddy; there are no eruptions, but a few insignificant scars from a burn can be seen on his back. The panniculus adiposis is fairly well developed. Glandular enlargements can not be detected. Heart and lungs appear normal in outline and function. Liver and spleen are not palpable. The pulse is rather slow and full, with fairly high tension. The secretions and excretions yielded negative results, with the exception of the stomach contents, which were deficient in free hydrochloric acid, but which did not show the presence of lactic acid, Boas-Oppler bacillus nor sarcinæ.

Nervous System: A slight difference in the innervation of the two halves of the face in favor of the left half becomes evident when the patient attempts to uncover his teeth, blow up his cheeks or move his jaw from side to side, but there is no difference on the two sides in transverse and longitudinal wrinkling of the brow and in the function of the orbicularis palpebrarum muscles. The tongue is somewhat tremulous and when protruded deviates slightly to the right. Although there is no paralysis or paresis of any muscles, the grip is rather weak in both hands, but slightly better on the left side. Strength is not appreciably diminished in the lower extremities except that the right leg is not as strong as the left. Coordination is normal in both upper and lower extremities, but the patient at times presents a peculiar staggering gait which is neither of the tabetic nor the cerebellar type.

The superficial reflexes are normal and equal on both sides. The upper reflexes are somewhat brisk, slightly more so on the right side. The left knee-jerk is about normal, the right is slightly in excess. Ankle clonus is barely indicated on the right and doubtful on the left side. There is no Babinski, Oppenheim nor Gordon reflex. Sensation is unimpaired in all its qualities.

Eyes: The range of vision is normal. There was no diplopia, ptosis, strabismus, exophthalmos nor Argyll-Robertson pupil. The optic fundus findings were considered within normal limits by Dr. Brown Pusey.

Mentality: The patient is mostly depressed and worries greatly over his disease and about his family. He never indulged in flippant talk, the so-called *Witzelsucht* of German writers. His speech is rather slow and labored and is quite unintelligible, perhaps partly because of his ignorance of English.

Course of Disease.—The course of the disease was comparatively rapid. At no time was there a temperature, except immediately before death. The pulse ranged from 64 to 90 and only became frequent toward the end, when 150 to the minute was registered.

March 22, 1905, it was noted that the left palpebral fissure was wider than the right and that the left pupil was somewhat dilated and reacted sluggishly to light.

On April 15, 1905, I could easily make out a double optic neuritis. Dr. Brown Pusey, at my request, examined the patient April 18, 1905, and he kindly reports the following: Double papillitis very distinct on left side; not so well marked on right side. No hemorrhages or exudates. Pupils react to light and in accommodation.

The patient frequently groaned from pain and would place his hands over the frontal region as though to indicate the exact location of his pain. Slight physical or mental strain, such as walking or being interrogated about his symptoms, always aggravated the headache. No bruit could be heard over any portion of the cranium and percussion failed to elicit the cracked-pot resonance occasionally noted in brain tumor.

Somewhat toward the end the right-sided weakness previously mentioned became more pronounced, without, however, developing into distinct loss of power. Not even at this time did Jacksonian or other convulsions make their appearance. The patient became more apathetic and was even stuporous at times, but even now he could be sufficiently aroused to answer questions. A skiagraphic picture taken by Dr. Fischkin of the Cook County Hospital showed nothing of value from a diagnostic point of view.

Diagnosis.—Here is a patient with headache, vomiting, vertigo, general weakness, optic neuritis and gradually deepening mental apathy with staggering gait. In addition there is a slowly developing weakness of the right half of the body, objectively demonstrable in the face and arm, but not so well in the lower extremity.

Following the usual rule of dividing symptoms of brain pressure into general and focal symptoms, we can find both sets of symptoms in this case. Among the general symptoms must be counted headache, vomiting, vertigo, optic neuritis, generalized weakness. Of localizing value was the difference in the muscular strength on the two sides of the body, possibly the more pronounced papillitis on the left side, and the mental apathy and tendency to somnolency. In the absence of symptoms pointing to cortical irritation, such as Jacksonian fits or muscular twitchings of any kind, I considered the neoplasm to be most probably subcortical in location. The right-sided weakness in arm and face determined me to locate the tumor on the left side of the brain in the region of the anterior central convolution bordering the Rolandic fissure and probably extending from about the junction of the upper with the middle third down near to the base, but not involving the base of the brain. This diagnosis was made largely on a consideration of the recent findings of Krause of Berlin, which were published in the *Deutsche Klinik*. In his article Krause states emphatically that our old schemes of cerebral localization have become obsolete and are inadequate for practical needs in brain surgery. In his experience the face, arm and part of the leg center were found principally in the ascending frontal convolution, anterior to the Rolandic fissure, and not, as heretofore taught, in the postcentral convolution. He arrived at his conclusions by his routine method of stimulating the brain with faradism before operating. In his efforts to localize the motor centers he uses the unipolar method instead of bipolar faradization, and he has been able to get uniform results. The motor centers in man, according to his experiments, are situated anterior to the Rolandic fissure, notwithstanding the experiments made on the monkey and with the bipolar method which place these centers principally in the postcentral convolution.

---

* From Cook County Hospital.

Treatment.—The patient was from the first placed on mixed antisyphilitic treatment. He was given inunctions of mercurial ointment and large doses of potassium iodid, but without any benefit.

As the patient was becoming more stuporous and as internal treatment had failed to produce the slightest change in his condition, I recommended a transfer to the surgical side. On April 28, 1905, the patient was assigned to Dr. Schroeder for surgical treatment, who concurred with me in the diagnosis and the advisability of an operation. It was evident to all of us, judging from the patient's condition, that an operation was indicated as affording the only possible chance of prolonging life. It was my opinion that the tumor was subcortical, and probably situated on the left side in the ascending frontal convolution. The symptoms in this case did not justify an expression of opinion regarding the pathology nor whether the growth was circumscribed or of the infiltrating kind.

Operation.—Dr. Schroeder, assisted by Drs. Quick and Dyas, performed the operation May 4, 1905. For the following notes I am indebted to Dr. Schroeder, who has taken an unusual interest in this case:

"A large osteoplastic flap was turned down on the left side of the head, as follows: A horseshoe shaped incision was first made through the skin, then a small trephine hole through the bone on either end of the incision, which openings were then united by means of the DeVilbiss forceps. The bridge was only partially cut across and the flaps elevated. The dura was then incised and reflected to either side. When the brain was exposed no sort of pulsation could be seen or felt. The soft membranes appeared normal, but a dense resisting mass could easily be felt just anterior to the Rolandic fissure, which appeared to be at some depth from the surface. It was decided to cut into the brain mass with a view of exploring the tumor. A dense mass of brownish tissue was encountered which seemed to extend rather deeply and did not appear to be clearly defined from the surrounding normal tissue. At this step of the operation it became evident that the tumor was not removable and after cutting out a piece for microscopic examination, the operation was abandoned. A drain of iodoform gauze was introduced to guard against pressure from hemorrhage and the dura was sutured with catgut. Marked paralysis of the right arm and leg appeared within a few hours after the operation. The patient was in great pain, moaned constantly and never entirely recovered consciousness. His condition kept growing worse, pulse and respiration became rapid and irregular, until toward the end 160 beats to the minute could be counted. The temperature rose to 106.8 just before death, which occurred on May 5, 1905."

Postmortem Findings.—The examination was made by the resident pathologist and internes at Cook County Hospital. Omitting unimportant details, I find recorded the following anatomic diagnosis:

1. Tumor in the left cerebral hemisphere.
2. Purulent right-sided bronchopneumonia.
3. Acute parenchymatous myocarditis.
4. Tracheobronchial adenitis.
5. Parenchymatous degeneration of liver, pancreas and kidneys.

Owing to a misunderstanding the cord was not removed and, therefore, no report could be rendered.

The brain weighed 1,500 grams and showed no abnormal changes in the membranes. An operation wound in the left hemisphere revealed a tumor at some depth from the surface, situated in the region of the ascending frontal convolution. The neoplasm was not sharply defined from the surrounding brain tissue, except that it was more reddish in color and had a denser consistency. Approximately it was three inches in length, two inches in its widest diameter and it seemed to extend from above downward for a distance of about one and one-half inches. Microscopically it showed the following: With low magnification an immense number of nuclei was the most striking picture. With the high power lens many filamentous processes could also be observed to radiate in all directions without any apparent regularity. The cells are mostly small and have round or slightly oval nuclei. The macroscopic and microscopic appearance of the growth leaves no doubt of its being a glioma.

The case just reported illustrates, among other things, that, no matter how ill-defined, focal symptoms must be present before a localizing diagnosis can be attempted. Without some such signs as unilateral weakness, paresis, or exaggerated reflex, slight aphasia, etc., it would have been impossible even to guess at the location of the tumor.

One symptom of localizing value had not been properly appreciated in our case, owing to the patient's imperfect knowledge of English. I refer to his mental dullness early in the disease, which would have been of distinct value in attracting attention to the frontal lobe as the seat of the neoplasm, had we been certain of his former mental state.

An interesting negative symptom was the absence of Jacksonian fits or muscular twitchings of any kind throughout the disease. Its value consisted in excluding cortical involvement and enforcing strict conservatism from a surgical point of view. Even if epileptic fits had occurred late in the disease, their significance as a focal sign would have been doubtful, as spasms often occur in tumors that originate in the white substance of the brain and gradually grow outward, irritating the cortex.

The indefinite symptoms are easily explained by the fact that gliomata of the infiltrating type are usually of slow growth, and the brain tissue gradually accommodates itself to new conditions. It is not rare for patients with brain tumor to masquerade as subjects of neurasthenia or hysteria on account of their supposed functional symptoms until some one discovers a choked disc or until the patient develops more typical signs of brain tumor.

That the topical diagnosis was correctly made was proved on the operating table and postmortem examination. It is true that we have learned something about cerebral localization, but all we know definitely refers principally to the so-called motor area of the brain. And it would appear that even this supposed definite knowledge must be considerably modified in the light of recent acquisition. Heretofore the motor area was considered to be principally situated in the ascending frontal and ascending parietal lobes, but principally in the latter. Now it develops that Sherrington,[1] by his recent experiments on the chimpanzee, has found that the motor area was not as extensive as previously supposed, and that it lies entirely in front of the fissure of Rolando, i. e., entirely within the frontal lobe.

Campbell,[2] in his histologic researches, was able to claim the same situation for man. Bolton[3] unqualifiedly accepts the view of the before-mentioned authors. It was reserved, however, for surgeons of the stamp of Krause[4] to demonstrate the truth of these statements on living human beings, anesthetized and ready for operation.

A point worthy of mention in connection with this case is our utter inability to make a positive, or even probable, anatomic diagnosis of brain tumor; viz., whether we have syphiloma, tuberculoma, glioma or sarcoma.

In conclusion, this case offers an additional example of the well-known fact stated by Oppenheim,[5] Starr,[6] Gowers,[7] and others, that glioma must almost always be considered an inoperable tumor, because of its tendency to infiltrate and because it is usually deeply situated in the white substance of the brain.

In the same sense G. L. Walton and W. E. Paul[8] are worth quoting. They say:

> The prevailing skepticism among pathologists regarding the operability of gliomata seems well founded. Such tumors involve a tendency to faulty growth inherent in the brain substance itself, a tendency to which no boundary can be set, and which can no more be checked than the tendency of fruit to decay after removing the portion obviously decayed, a comparison already rather too favorable for the brain, because the difficulty in determining the extent of brain destruction in case of a glioma by exploratory operation is, as a rule, much greater than that of determining the limit of decay in the fruit.

100 State Street.

THE MANAGEMENT OF TYPHOID FEVER.*

J. F. JENKINS. M.D.

TECUMSEH, MICH.

As soon as a diagnosis of typhoid fever is made, or even in a suspicious case, it is better to place the patient in a recumbent posture, and to keep him in that position throughout the whole course of the disease.

Positive orders must be given to the nurse to change the position of the patient from side to side, or from the back to the side, every two or three hours. One should examine the heart and lungs, as well as the abdomen, from day to day, as long as the patient is under observation, and he should not assume the erect position at any time during the continuation of the fever, either for the purpose of taking nourishment or drink; and, however obstinate the patient may be, one should insist on his using the bed-pan on all occasions when it is necessary.

It is a well-known fact that the diet in typhoid fever is of the utmost importance, and that solid food should not be permitted under any circumstances from the beginning of the fever until ten days after its termination. It is well known that beef tea and broths make an excellent culture medium for the typhoid bacillus, and therefore it is well to omit them from the diet list. This error in diet doubtless accounts for the excessive diarrhea often observed in patients who are allowed to have these broths. Milk, from a quart to a quart and a half, preferably given with pepsin and hydrochloric acid, and two soft-boiled eggs every twenty-four hours, make a very efficient diet during the whole course of the fever. Frequently, barley water or rice water may be given for a change. In the later stages of typhoid fever, a stimulant in the form of old whiskey may be added to the milk, especially if there is a flagging pulse. In the early stage of typhoid fever, fractional doses of calomel, followed by a small dose of Rochelle salts or soda phosphate, is indicated; in many cases the above preparations may be repeated from time to time during the first and second weeks.

The gate of entrance of the typhoid bacillus is the alimentary canal, and Peyers glands, situated in the small intestines, appear to suffer from their attack more than any other portion. Intestinal antiseptics are prescribed by many physicians, but they do not destroy the typhoid bacillus in the intestinal canal, or in the circulatory system, which they frequently invade even before one has had an opportunity of examining the patient. Bacteriologists state, however, that antiseptics do destroy the non-specific bacteria that invest the intestinal canal, combat fermentation to a certain degree and lessen the foul odor emanating from the discharges of the intestinal canal. By their antiseptic influence they lessen the diarrhea, as well as the tympanitis; therefore, they are useful and should be prescribed.

Among the many remedies exerting an antiseptic influence in the alimentary canal, one may mention salol, turpentine, sulphocarbolate of zinc and acetozone.

The temperature in typhoid fever rises from 100 F. to 105 F., and upward. When the temperature of the patient continues up to 102.5, antipyretic remedies are indicated. We have in cold water a remedy that fulfills every indication, either in the form of the sponge bath, the cold pack or tubbing. The cold sponge bath will reduce the temperature, although it may be necessary to repeat the bath every hour or two; occasionally, ice cold water is required to reduce the temperature. Cold drives the blood to the internal organs; hence it is advisable to follow up the bath by vigorously rubbing the surface with a coarse linen or crash towel. Frequently a small quantity of stimulants is indicated after the bath. When delirium, restlessness or coma is a prominent feature, the ice cap continuously applied to the head—although it will be necessary to change its position from time to time—will greatly relieve the patient and often produce a natural sleep. During convalescence a tepid sponge bath of equal parts of alcohol and water two or three times a day has a beneficial effect on the patient. One should insist on the nurse giving the patient from a quart to a quart and a half of boiled water every twenty-four hours, for the typhoid patient does not usually call for water, even when his temperature is high.

In a large proportion of cases diarrhea is excessive; frequently it is aggravated by an excessive quantity of food, or by food which is not assimilated. A change in the quantity and quality of the food will have much to do in lessening the diarrhea. Bismuth subnitrate in large doses frequently repeated will usually check the excessive discharge from the bowels. Subsultus tendinum in the terminal stage of the disease is usually accompanied with great restlessness; for which in recent cases I have found Hoffman's anodyne, as recommended by Hare, a very useful remedy.

In the later stage of typhoid fever, the feeble heart's action calls for support; and one must instruct the nurse relative to the necessary stimulants to sustain the circulation. During convalescence the urine is loaded with the typhoid bacillus. Hexamethylenamin in 5-grain doses, repeated three times a day, well diluted with water, and continued for a week or ten days, will destroy the bacillus in the urine.

Special Article

THE PHYSICIAN AND THE PHARMACOPEIA.

CHAPTER II.

EXPECTORANTS.

The prevalence of coughs and "colds" in the winter months is sufficient evidence of the importance of this class of agents. Their use in domestic practice—largely as "patent medicines," so called—probably exceeds that directed by the physician as ten to one.

Physicians are supplied liberally with literature by manufacturers of proprietary remedies, but the pharmacology of this literature is not always worthy of the faith that some physicians place in it. As an example we quote from a circular distributed exclusively to physicians: "In severe and frequent cough, when little mucus is secreted, as shown by the scanty viscal sputum, morphin, or, better, its derivative, ethyl-morphin, is indicated, which increases secretion and lowers excitability of the respiratory center." For comparison with this interested statement by the manufacturers we quote from the article on opium in Wood's Therapeutics (11th ed., p. 716): "Its tendency to check secretion forbids its use, however, in a very large proportion of cases, notably in those in which there is persistent dryness of the bronchial mucous membrane." Sollmann, Cushny and others state that morphin possesses the same property, though to a lesser degree than opium.

In such circulars manufacturers usually advocate the use of some certain remedy for all coughs, but we may be pardoned if we again quote Wood for comparison: "It is plain that the medical practitioner must study in each individual case the relations between the cough and the amount of work required."

The discovery of a medicinal agent is the signal for a host of imitators whose product may differ, if at all, merely in the substitution of an ethyl for a methyl group, or of one harmless acid radical for another. These are presented in increasing numbers to the physician, who can by no possibility remember them all. Or some well-known drug, whose length of service, if not merit, entitles it to some respect, is seized on to serve as a basis for fabulous claims, perhaps long since voiced, disproved and forgotten.

There is still another interesting phase connected with these various nostrums. Many of us pride ourselves on the fact that we use only "ethical" preparations and also that we insist on knowing just what we are prescribing or using. It must be rather embarrassing, therefore, to find that even the public is more exacting in this respect than we are and that the manufacturers of popular medicines, when they do advertise the composition of their particular mixture, publish a full and complete formula and not an incomplete one such as we frequently find in the advertising pages of medical journals, or in the circulars that come to our desk.

Ayer's Cherry Pectoral Versus Pruni-Heroin.

Concrete examples, however, are so much more effective than mere generalities that we select—almost at random—two advertisements for comparison. Surely no physician of our day would prescribe "Ayer's Cherry Pectoral." How many prescribe the much-vaunted "Pruni-Heroin?" Let us compare these formulas, the one from the lay press, the other from nearly any medical journal. Note that the advantage of complete publicity lies with Ayer; whether correctly or not, the quantities are all given.

AYER'S CHERRY PECTORAL.

Each fluid ounce[1] represents
Wild cherry ......6 grains.
White pine ....4 grains.
Terpin hydrate....4 grains.
Blood root ....2 grains.
Heroin (!)......1/6 grain.
Grindelia robusta..4 grains.
Senega ....4 grains.
Rio ipecac ....2 grains.
Glycerin.
Alcohol ....80 m.
Syrup.
Water.

PRUNI-HEROIN.

Each fluid ounce represents
Wild cherry bark.
White pine bark.
Terpin hydrate.....4 grains.
Blood root.
Heroin ....1/6 grain.
Ammon muriate...16 grains.
Spikenard.
Glycerin.
Solvents.
etc.

If Ayer's "shotgun" Pectoral ought to be considered obsolete, what shall we say of Pruni-Heroin? If a physician prescribe Pruni-Heroin and condemn Ayer's to a patient who has taken Ayer's, what will the patient think of the advice if he learns the composition of Pruni-Heroin?

Expectorants in the Pharmocopeia.

The expectorants official in the United States Pharmacopeia afford a great variety of choice. Innumerable combinations are possible, but we shall merely suggest a few of these, in connection with some of the drugs and preparations available.

It should be remembered that coughing serves to remove mucus from the respiratory tract and usually requires no treatment. If this becomes unduly severe, it may require alleviation; if the secretion is scanty it may be increased or rendered more liquid.

Acute bronchitis may be divided into two general stages, with certain expectorants useful in each stage, but this is not *to be taken as a rigid classification.*

The first stage—that of dryness of the mucous membrane, with considerable cough—calls for sedatives; the second—that of *free secretion—requires stimulant expectorants.*

Sedative Expectorants.

Among the official sedative expectorants to be used in the first, or dry, stage of cough we have the following:

Ipecac.

Ipecacuanha.—U. S.—Ipecac is the dried root of *Cephaëlis ipecacuanha* (Brotero), A. Richard (Fam. *Rubiaceæ*). It is known commercially as Rio, Brazilian or Para Ipecac, or the corresponding portion of *C. acuminata*, Karsten, known commercially as Carthagena Ipecac, yielding, when assayed by the process given in the Pharmacopeia, not less than 2 per cent. of ipecac alkaloids. Ipecacuanha was first described by Piso and Markgraf, in 1648, in their natural history of Brazil. The drug appears to have been well known to the natives of Brazil and to have been much prized for a variety of therapeutic purposes. It was introduced into Europe, about 1675, by John Helvetius, of Paris. The Carthagena variety of Ipecacuanha is a comparatively recent introduction, being first noted as a distinct variety, about 1870. Ipecacuanha is official in all pharmacopeias, but up to the present time the Pharmacopeia *of the United States is the only one to recognize the* Carthagena variety as being the equal of the Brazilian.

Pulvis Ipecacuanha.—U. S.—Average dose: Expectorant, 0.050 gm. (1 grain); emetic, 1 gm. (15 grains).

Fluidextractum Ipecacuanhæ.—U. S.—Fluid extract of Ipecac.—Extractum Ipecacuanhæ Liquidum Br. should contain 1.75 per cent. of alkaloids.

Average Dose: Emetic, 1 c.c. (15 minims); expectorant, 0.05 c.c. (1 minim).

Pulvis Ipecacuanha et Opii.—U. S.—Powder of Ipecac and Opium. (Dover's powder.) This contains 10 per cent. of ipecac, 10 per cent. of powdered opium and 80 per cent. of sugar of milk.

Average Dose: 0.500 gm. (7½ grains); used chiefly as a diaphoretic.

Syrupus Ipecacuanhæ.—U. S.—Syrup of Ipecac. This contains 7 per cent. of Fluidextract of Ipecac and 1 per cent. of Acetic acid in a mixture of glycerin, sugar and water.

Average Dose: Expectorant, 1 c.c. (15 minims); emetic, 15 c.c. (4 fluidrachms).

Vinum Ipecacuanhæ.—U. S.—Wine of Ipecac. A mixture of 10 per cent. of Fluidextract of Ipecac, 10 per cent. of alcohol and 80 per cent. of white wine.

Average Dose: 1 c.c. (15 minims).

---

[1] We give ounces instead of drams to facilitate comparisons.

When the bronchi are inflamed and the secretion is scanty or thick and tenacious, nauseants, such as ipecac, lead to increased secretion which secures its removal by coughing. The choice of nauseants is guided by the general condition of the patient, ipecac being preferred to Antimony and Potassium Tartrate in those cases (children and weakly persons) in which great depression would be dangerous. The active principle of ipecac is not usually employed in the pure state as an expectorant, the syrup of ipecac being preferred, as the tannin present retards absorption and prolongs the action.

The expectorant dose of the nauseants is always very much less than the emetic—approximately one-tenth in the case of ipecac. The average doses given are approximate and the expectorant dose is to be repeated every two or three hours; the emetic dose is to be repeated half-hourly until effective.

For croup in small children few remedies enjoy a greater reputation than syrup of ipecac, which is given alone in doses of from ten to thirty drops, repeated at intervals of thirty minutes until vomiting occurs.

A Typical Ipecac Prescription.

The preparations of ipecac are seldom used alone as expectorants, but are usually added to mixtures of allied use.

The following may be considered a typical prescription for ipecac to be used in teaspoonful doses every two hours; for the syrup of ipecac a corresponding amount of fluidextract or wine may be substituted. When an opiate is imperatively demanded 15 c.c. (4 drachms) of camphorated tincture of opium may be added without other change:

℞.	Syrupi ipecacuanhæ	ʒvi	25
	Ammonii chlorid	℥iss	6
	Syrupi tolutani, q. s. ad	ʒiii	100

Senega.

Senega.—U. S.—Root of *Polygala senega*—Radix Senega—is one of the few drugs of American origin that has found a place in every recent pharmacopeia. It contains a saponin which is locally irritant, but which is not absorbed; hence, the drug is not depressing. It is almost invariably used in small amount as an addition to other expectorants. It has the disadvantage of an unpleasant acrid taste. The official preparations are:

Fluidextractum Senegæ.—U. S.—Average dose, 1 c.c. (15 minims), and

Syrupus Senegæ.—U. S.—This contains 20 c.c. Fluidextract of Senega in 100 c.c.

Average Dose: 4 c.c. (1 fluidrachm).

See also Syrupus Scillæ Compositus.

Sanguinaria.

Another irritant nauseant more notable for its abuse than use is:

Sanguinaria.—U. S.—Rhizome of *Sanguinaria canadensis* (bloodroot). This drug, usually omitted by modern therapeutists or dismissed with a line, contains sanguinarin, belonging to the morphin group, and causing depression of the respiratory center. It is mentioned here more particularly because of its widespread use by the nostrum makers. The common name—bloodroot—appears to possess considerable psychical effect. The Indians, perhaps, displayed more wisdom in its use than we do; they only applied it externally, as war paint. The only official preparation is:

Fluidextractum Sanguinariæ.—U. S.

Average Dose: 0.1 c.c. (1½ minims).

The "Compound Syrup of White Pine" of the national formulary represents the "popular" expectorants. It is not recommended, however, as it is too complicated.[1]

Antimony.

Antimony and potassium tartrate is a more depressing nauseant than the drugs above mentioned. It may be used on robust persons, but not with safety on children or the infirm. Its mode of action is similar to that of ipecac, and here, too, we have a variety of official preparations.

Antimonii et Potassii Tartras.—U. S.—Antimony and Potassium Tartrate; Antimonium Tartaratum Br., Tartarus Stibiatus Ger., Tartar Emetic. Colorless, transparent crystals or a white granular powder, soluble in 15.5 parts of water, insoluble in alcohol. It was discovered in 1631 by Mynsicht, whose process of manufacture was subsequently improved by Glauber. It has long been the most popular and widely used of the medicinal compounds of antimony, and is now official in all recent pharmacopeias, the official nomenclature differing widely, however.

Average Dose: Expectorant, 0.005 gm. (1/10 grain); emetic, 0.03 gm. (½ grain).

Vinum Antimonii.—U. S.—Wine of Antimony. This contains 0.4 per cent. of Antimony and Potassium Tartrate in solution in 1 part of alcohol and 5 parts of white wine, and enters the well-known compound mixture of glycyrrhiza—a deservedly popular expectorant.

Average Dose: 1 c.c. of the wine (15 minims).

Mistura Glycyrrhizæ Composita.—U. S.—See Glycyrrhiza.

Tartar Emetic is an ingredient (0.2 per cent.) in the Compound Syrup of Squill, which see below.

For the administration of Antimony and Potassium Tartrate, the official Compound Mixture of Glycyrrhiza (6 per cent. Wine of Antimony, —0.024 per cent. Antimony and Potassium Tartrate) is used alone or with 4 gms. (60 grains) Ammonium Chlorid to 60 c.c. (2 ounces). A typical prescription follows:

℞.	Vini antimonii	ʒiv	15
	Aquæ chloroformi, q. s. ad	℥iii	100

A teaspoonful every two hours.

Apomorphin.

Apomorphinæ Hydrochloridum.—U. S.—Apomorphin hydrochlorid.—The hydrochlorid of an alkaloid prepared from morphin by the abstraction of one molecule of water. Soluble in 40 parts of water, in the same proportion of alcohol, practically insoluble in all other solvents.

Apomorphin is much less useful as an expectorant than as an emetic, its action being brief.

Average Dose: Expectorant, 0.002 gm. (2 mg. or 1/30 grain); emetic, 0.005 gm. (5 mg. or 1/12 grain).

Ammonia.

Ammonii Chloridum.—U. S.—Ammonium Chlorid Br. Ammonium chloratum Ger. A white crystalline powder, without odor, having a cooling saline taste, permanent in air, soluble in 2 parts of water and in 50 parts of alcohol.

As sal ammoniac, this substance has been known from a very early time. It is popularly supposed to have been first obtained from the neighborhood of the Temple of Jupiter Ammon, in Northern Africa.

Ammonium Chlorid was known to the Arabian physicians and was described by Geber. It is now official in all recent pharmacopeias. Wood recommends this salt in the stage just before secretion becomes free; for this purpose the following may be used:

Trochisci Ammonii Chloridi.—U. S.—Each troche contains 0.1 gm. (1½ grains) Ammonium Chlorid and 0.2 gm. (3 grains) Extract of Glycyrrhiza.

Ammonium chlorid is much used as an addition to Compound Mixture of Glycyrrhiza in the proportion of 4 gms. (60 grains) to 60 c.c. (2 ounces), and it may be added to nearly any expectorant mixture which is not strongly alcoholic.

STIMULATING EXPECTORANTS.

Tolu.

Balsamum Tolutanum.—U. S.—Br.-Ger.—Balsam of Tolu, a balsam obtained from *Toluifera balsamum*, a yellowish-brown, plastic solid that has a pleasant aromatic odor and a mild aromatic taste. It is readily soluble in alcohol, nearly

---

[1] The following is the formula for the Compound Syrup of White Pine:

White pine bark (pinus strobus)	℥iss	75
Wild cherry bark	℥iss	75
Spikenard root	ʒiss	10
Balm of Gilead buds	ʒiss	10
Sanguinaria root	ʒii	8
Sassafras bark	grs. cv	7
Morphin sulphate	grs. viiss	5
Chloroform	ʒiss	6
Sugar	ʒxxvss	750
Alcohol		
Water		
Syrup (U. S.), of each, to make	Oii	1000

insoluble in water. Balsam of Tolu was first described by Monardes, a Spanish physician, about 1574. The drug, it is said, was collected in a district near Carthagena, called Tolu, and appears to have been well known to and used by the natives of Northern South America. Balsam of Tolu, at the present time, is a widely used and popular drug and is official in all of the leading pharmacopeias.

Average Dose: 1 gm. (15 grains).

Syrupus Tolutanus.—U. S.—Syrup of Tolu, containing the water-soluble principles of 5 per cent. of Tincture of Tolu in Syrup.

Average Dose: 15 c.c. (4 fluidrachms).

Tinctura Tolutanæ.—U. S.—Tincture of Tolu, a 20 per cent. solution of Tolu in alcohol.

Average Dose: 2 c.c. (30 minims).

The mildest of the stimulant expectorants is Syrup of Tolu, if, indeed, this can be considered as anything more than a flavored syrup. The balsam is not infrequently used in medicine, but may be given in the form of an emulsion made with acacia and water and sweetened with sugar.

The benzoic acid and volatile oil in the balsam give it the advantage of being mildly antiseptic, the syrup, however, being too weak to be effective in the dose usually employed.

Balsamum Peruvianum.—U. S.—Balsam of Peru may be used in the same dose and for the same purpose as Balsam of Tolu.

Attention is called to the fact that the urine of persons taking such amounts of these balsams gives a precipitate with nitric acid which may be mistaken for albumin, but the precipitated resins dissolve in alcohol, while albumin does not.

Benzoin.

Benzoin.—U. S.—This balsamic resin is also a harmless stimulant, useful in bronchial irritation.

Tinctura Benzoini.—U. S.—A 20 per cent. solution of Benzoin in alcohol, or:

Tinctura Benzoini Composita.—U. S.—"Turlington's Balsam," commonly called "Friar's Balsam" (also containing Benzoin, Aloes, Storax and Tolu), also may be given.

Average Dose: 1 c.c. (15 minims) every two hours.

The fact that these expectorants are harmless is a very great advantage—and is a point to be particularly remembered in the treatment of small children, in whom opiates and such depressants as antimony and potassium tartrate are to be avoided.

Tar.

Syrupus Picis Liquida.—U. S.—Syrup of Tar.—Containing one-half of 1 per cent. of the soluble principles of tar in syrup, is mildly stimulant and the taste is not unpleasant.

Average Dose: 4 c.c. (1 fluidrachm).

Tar itself has a disagreeable acrid taste and is not often used in substance.

Terpin Hydrate.

Terpini Hydras.—U. S.—Terpin Hydrate.—This is a body closely related to turpentine, camphor, etc. It occurs in colorless, lustrous, rhombic prisms, or a white crystalline powder, nearly odorless, of a slightly aromatic and somewhat bitter taste, soluble in about 200 parts of water and in 10 parts of alcohol.

Average Dose: 0.1 gm. (2 grains) in capsules or elixir. Owing to its slight solubility in water, the elixir must be strongly alcoholic and glycerin be substituted for syrup—a serious objection to its general use. It is very commonly associated with codein, which is also not to be recommended for routine practice.[2]

Terpin Hydrate has been known for some time, but was not used in medicine until after Lepine published the results of his physiologic investigations in 1885. It is supposed to possess the antiseptic and stimulating effects of turpentine without possessing its irritating properties. The substance soon became popular and was included in the United States Pharmacopeia for 1890. It is also official in the German Pharmacopeia and in the French Codex.

It has been suggested as a remedy in a variety of ailments, but it appears to be useful mainly as an expectorant, enjoying a reputation particularly among the nostrum vendors. It is, in reality, useful in aiding to get rid of secretion from the bronchial mucous membrane.

Terebene.

Terebenum.—U. S.—Terebene.—This is a polymerization product derived from turpentine which it closely resembles.

It is a colorless liquid, having a rather agreeable odor and an aromatic, somewhat terebinthinate taste, readily soluble in 3 times its volume of alcohol, but only slightly soluble in water.

First obtained by Soubeiran and Capitaine about 1841, it was introduced into medicine by Dr. William Murrell about 1885; it was made official in 1890 and in the British Pharmacopeia of 1898.

It is used in much the same conditions as Terpin Hydrate; its immiscibility with the mixtures usually employed as expectorants has interfered in no small way with its employment. It may be prescribed in alcoholic solution, in capsules or in the form of an emulsion.

Average Dose: 0.5 c.c. (8 minims).

Squill.

Scilla.—U. S.—Squill. The bulb of *Urginea maritrima*, containing several potent principles, it is exceedingly irritant and in large doses toxic.

Average Dose: 0.1 gm. (2 grains).

Of all the official drugs used in the treatment of cough, few are better known than squill, the syrup being the most popular of its preparations.

This drug is both stimulant and nauseant; hence, it is used in both stages of bronchitis.

Syrupus Scillæ.—U. S.—Syrup of Squill. This represents 5 per cent. of Squill; made from Vinegar of Squill and, therefore. containing dilute Acetic Acid; it is, of course, incompatible with ammonium and other carbonates—a fact not infrequently lost sight of by the prescriber.

Acetum Scillæ.—U. S.—Vinegar of Squill. This represents 10 per cent. of the drug extracted with dilute acetic acid.

Average Dose: 1 c.c. (15 minims).

Fluidextractum Scillæ.—U. S.—Average dose, 0.1 c.c. (2 minims).

Tinctura Scillæ.—U. S.—This represents 10 per cent. of the drug.

Average Dose: 1 c.c. (15 minims).

These last three preparations of squill are seldom employed, but the following is widely used:

Syrupus Scillæ Compositus.—U. S.—Compound Syrup of Squill, Hive Syrup. This represents 8 per cent. of the Fluidextracts of Squill and Senega and 0.2 per cent. of Antimony and Potassium Tartrate or about 0.01 gm. (1/6 grain) to the teaspoonful.

Average Dose: 2 c.c. (30 minims).

The use of squill as an emetic is not free from danger and the drug is seldom so employed alone.

Creosote.—U. S.—(or Guaiacol.—U. S., which constitutes up to 90 per cent. of creosote) is used as a stimulant expectorant. There is considerable diversity of opinion as to its mode of action. It seems to possess little germicidal action so far as the lungs are concerned. When it is administered in a bland oil very large doses are tolerated, but this is not necessary for its expectorant effect.

Numerous compounds of creosote and of guaiacol have been suggested as substitutes for the official products, but it is not probable that they possess any decided advantages over the official. Those which are less poisonous are probably absorbed from the alimentary canal to a much less degree than are the official creosote and guaiacol.

Among the guaiacol compounds is the proprietary "Ethacol," containing ethyl-morphin, a fact to be carefully borne in mind, as the name of the preparation is not nearly so suggestive of morphin as of guaiacol. The manufacturers of this article recommend morphin or ethyl-morphin in bronchitis for increasing secretion! to which attention has already been called.

---

[2] It may be prescribed as the unofficial Elixir of Terpin Hydrate and Codein Sulphate. Dose: Two teaspoonfuls, containing 0.15 gm. (2 grains) Terpin Hydrate and 0.024 gm. (½ grain) Codein.

ANODYNES.

When the irritability of the throat causes excessive coughing anodynes are indicated. Morphin, however, must only be used with the greatest caution owing to its tendency to check secretion, "free circular therapy" to the contrary notwithstanding.

Codein.

CODEINA.—U. S.—Codein. Very soluble in alcohol, much less soluble in water.

CODEINÆ PHOSPHAS.—U. S.

CODEINÆ SULPHAS.—U. S.—Both are quite soluble in water, but not in alcohol.

Average Dose: 0.003 gm. (3 mg. 1/20 grain).

Codein, rather than its salts, is suited for combination with Terpin Hydrate, since both require alcohol as its solvent.

CODEIN has come very largely into use in expectorant mixtures in recent years, partly because its action resembles that of morphin without disturbing digestion or causing constipation in moderate doses, partly, no doubt, because manufacturers have popularized it in order to avoid the stigma attaching to the general use of morphin and opium.

Codein undoubtedly lessens cough, but, as already stated, this is not always desirable. Codein phosphate or sulphate, being soluble in water, may be added to almost any cough mixture which is not alkaline.[3]

Ammonium Chlorid is not well suited for combination with Terpin Hydrate, since the latter requires a strongly alcoholic menstruum which precipitates ammonium chlorid.

Numerous substitutes have been introduced for morphin and codein, but it has not been demonstrated that they possess all the advantages and none of the disadvantages of the officials. It must not be forgotten that habit may be formed with any of the morphin derivatives, including codein.

Attention has previously been called to the extreme similarity between Ayer's Cherry Pectoral and Pruni-Heroin, and the reader is invited to compare the extravagant claims made for Glyco-Heroin (Smith) with the action of heroin as stated by Sollmann and other accepted authorities.

Still another of the host of expectorant nostrums is "Syrup Codeia Compound—Bell," said to contain codein phosphate, *terpin hydrate*, eucalyptus and ipecac (compare with formula of Ayer's Cherry Pectoral).

The manufacturers of the "Syrup Codeia Co.—Bell" lay particular stress on the purity of their codein. The United States Pharmacopeia gives a very simple test for the purity of codein, which any physician may apply. We again invite a careful comparison of the *testimony* of accepted authorities concerning the constituents of this nostrum with claims made by the manufacturers.

The bromids of ammonium, potassium and sodium are safer than morphin, and are frequently beneficial when anodynes are indicated. Their doses should, however, be more than proportionately reduced for children.

Hydrocyanic Acid.

HYDROCYANIC ACID may be added to expectorant mixtures, but its action is fleeting and it must be frequently repeated.

ACIDUM HYDROCYANICUM DILUTUM.—U. S.—Contains 2 per cent. absolute HCN.

The average dose is 0.1 c.c. (1½ minims).

DEMULCENT EXPECTORANTS.

Demulcents are frequently employed to allay the irritation of the mucous membrane, and they possess the great advantage of being harmless. They may be administered in the form of lozenges or troches.

The following demulcents may be used as vehicles:

SYRUPUS ACACIÆ.—U. S.

MUCILAGO ACACIÆ.—U.S.

Licorice.

GLYCYRRHIZA.—U. S.—Licorice root is so well known as to require but little comment. Its preparations afford a variety of forms for administering it.

FLUIDEXTRACTUM GLYCYRRHIZÆ.—U. S.—This is the fluidextract of licorice root, from which a satisfactory syrup may be prepared by mixing 25 c.c. of the fluidextract with enough syrup to make 100 c.c.

Average Dose: 2 c.c. (30 minims).

EXTRACTUM GLYCYRRHIZÆ PURUM.—U. S.—This is a semisolid extract prepared from the root and is well adapted as an addition to extemporaneous mixtures.

Average Dose: 1 gm. (15 grains).

TROCHISCI GLYCYRRHIZÆ *et* OPII.—U. S.—This contains 0.005 gm. (5 mg. or 1/12 grain) of opium.

GLYCYRRHIZINUM AMMONIATUM.—U. S.—Ammoniated Glycyrrhizin is an excellent demulcent; it is readily soluble in water, but is *incompatible with acids.*

Average Dose: About 0.25 gm. (4 grains).

PULVIS GLYCYRRHIZA COMPOSITA.—U. S.—*Brust Pulver* Gr. Compound Powder of Glycyrrhiza, a laxative, containing Senna, Washed Sulphur, Glycyrrhiza, Sugar and Oil of Fennel, and is popularly believed to be a desirable adjuvant to expectorant medicines.

Average Dose: 4 gm. (60 grains).

MISTURA GLYCYRRHIZÆ COMPOSITA.—U. S.—Compound Mixture of Glycyrrhiza, Brown Mixture, containing Purified Extract of Glycyrrhiza and Acacia, each 3 per cent., syrup 5 per cent., with Camphorated Tincture of Opium 12 per cent., Wine of Antimony 6 per cent. and Spirit of Nitrous Ether 3 per cent.

Average Dose: 8 c.c. (2 fluidrachms).

This is a deservedly popular expectorant. It is very often prescribed alone, but is also much used as a vehicle for other expectorants, particularly ammonium chlorid.

Ammonia.

AMMONIUM CARBONATE.—U. S.—Ammonium Carbonate Br., Ammonium carbonicum Ger.

White, hard, translucent, striated masses of a strong odor of ammonia without empyreuma, and a sharp, saline taste, slowly but completely soluble in about 4 parts of water and decomposed by hot water.

A condition deserving especial mention is that in which the mucus is particularly thick and tenacious, requiring liquefaction; for this purpose, ammonium carbonate is frequently added to other expectorants; it has the disadvantage of an unpleasant taste, which can not be disguised with diluted acids because these decompose the carbonates.

The cough of chronic bronchitis requires the use of one of the stimulant expectorants, such as Terebene or Terpin Hydrate, bearing in mind the avoidance of those which will prove objectionable with continued use.

While urging the advantage of using the pharmacopeial agents, we particularly suggest that the physician consider the several ingredients of any nostrum instead of accepting the absurd and often grotesque claims of the manufacturers.[4]

---

[3] The following is suggested as a simple prescription containing codein:

R.	Codeinæ sulph.	grs. viii	5
	Ammonii chloridi	ʒiss	6
	Syrupi pruni. virg. q. s. ad	℥iii	100

M. Sig.: A teaspoonful every two or three hours.

Compound Mixture of Glycyrrhiza, Syrup of Tar, Syrup of Squill or Syrup of Tolu may be substituted, wholly or in part, for the syrup of Wild Cherry.

[4] Compare the following, purporting to have been written by a physician, with any text-book treating of the ingredients of which Respiton is alleged to be composed—5 grains, each. Asclepias (species ?) berberis and aromatics to the teaspoonful:

> "I have used Respiton in cases of La Grippe and on a a baby, 9 months old, for severe cough, with excellent results. H. E. Williams, M.D."

Constipation in Anemic and Chlorotic Subjects.—Sir Andrew Clarke recommended one-half grain each of aloin, ferri sulphas exsic., ext. belladonnæ, ext. nucis vomicæ, pulv. ipecac, pulv. myrrhæ and soap: One pill one hour before last meal, should bowels not act during the day. Osler uses a sulphur confection in the morning and a pill of iron, rhubarb and aloes throughout day. Shoemaker prescribes: ℞. Aloes purif. gr. iii; massæ ferri carb. gr. ii; pulv. aromat. gr. i: One or two pills at the bed hour. Exercise in the fresh air is, of course, a valuable adjunct.—*Denver Medical Times.*

Clinical Notes

A CASE OF COMPOUND DISLOCATION, WITH FRACTURE OF THE LEFT ULNA.

LOUIS B. HENKEL, JR., M.D.
ANNAPOLIS, MD.

After a careful search of the literature I have failed to find a case similar to the one described in this paper, and I am reporting this with the hope that it will be of benefit to other members of the profession.

Patient.—On Dec. 29, 1903, C. H., aged 24, was admitted to the Emergency Hospital of this city.

History.—While ascending a ladder in the afternoon of the same day he had fallen about fifteen feet to the ground below. With some building material in his hand he had ascended about two-thirds of the latter and, turning around, he lost his balance and fell to the ground below. He landed on the palm of his right hand, left wrist, knees and face. The injury to the right palm was of the lacerated variety, which required six sutures to close the wound, after which it was dressed with 10 per cent. iodoform gauze and redressed every day for a week. The sutures were then removed, the wound having healed by first intention. The injuries to the knees and face were simple contusions, the former healed completely under iodoform gauze dressing in about five days; the latter healed, except the slight discoloration, in about ten days under bichlorid and later alcohol compresses. More important than the injuries I have just described, and that which has led me to report this case, was the injury to the left forearm. The man, as I have mentioned above, landed on his left wrist, etc., and as soon as his wrist struck the ground dislocation of the ulna occurred, with the free end of the ulna piercing the muscles, fascia, cutaneous and other tissues, the result being a "compound dislocation." From the history which the patient gave and from the appearance of the wound, I concluded that the end of the ulna, which was protruding through the tissues of the wrist, had struck the ground, thus causing the splintering which had occurred of that end of the ulna. I made a diagnosis of "compound dislocation, with a comminuted fracture" of the left ulna.

Treatment.—The patient arrived at the hospital at 6:30 p. m., and was evidently under the influence of alcohol, which I later learned was given to him by his friends in the hope of relieving his pain. His injuries had been dressed by one of the physicians at the Naval Academy Hospital, after which the patient was removed to the Emergency Hospital. I found the patient a little stupid and suffering a good deal of pain, for which I directed the nurse in charge to administer morphia, gr. ¼, with atropia, gr. 1/150, and to repeat the injection, if necessary, to quiet the patient. After an inspection of the injuries I concluded to wait until it was necessary to redress them and not to interfere with what had already been done. I remained with the patient about two hours; then left him in charge of the nurse for the night. The next morning I called to see patient, and was informed by the nurse in charge that the morphia and atropia had had no effect and that the patient had been suffering all night. On inspecting the dressings I found that they were thoroughly blood stained, and deemed it wise to investigate the cause for so much bleeding. Removal of the dressings from the left forearm showed the splintered end of the ulna protruding through a lacerated wound of the soft parts of the left wrist, which had been sutured with catgut and, I am sorry to say, had not proved adequate for the injury. I removed the loosened sutures and could then clearly see that the distal end of the ulna, which was protruding, was splintered to such an extent as to make it triangular, with an apex, instead of being more or less blunt as is the case in the normal bone, the styloid process being broken off.

Operation and Result.—Under general anesthesia I proceeded to repair the injury. I found it impossible to return the free end of the ulna through the opening made by its exit, so extended the opening up the forearm by an incison about three inches, and then, after catching up and ligating all bleeding vessels, I was able to reduce the dislocation by extension, flexion inward and outward of the hand, and manipulation, my assistants retaining the ulna in position while I closed up the wound with ten interrupted sutures. A plaster of Paris bandage was then applied, an oblong window being left over the wound which was dressed with 10 per cent. iodoform gauze after thorough irrigation with 1 to 1000 bichlorid solution. The injuries to the right palm and knee were also dressed with 10 per cent. iodoform gauze after bichlorid irrigation. The lacerated wound of the right palm required six sutures to close it. Both palm and knee had entirely healed by the sixth day, at which time the sutures were removed from the palm. The injury to the left forearm was dressed every second day, then every third day, until the sutures were removed at the end of four weeks, the wound having healed by third intention. The plaster bandage was removed at the end of three weeks. After massage with alcohol I put up the wrist in an anterior and posterior splint, which I kept on for about ten days. After removal of the splints, passive movements and massage were ordered and gradually increased until the patient was allowed to rotate and to flex his hand as much as possible. The wound healed up entirely, and the patient was discharged at the end of the seventh week with fairly good movement.

SUCCESSFUL AMPUTATION OF THE PENIS FOR EPITHELIOMA.

L. SEXTON, M.D.
NEW ORLEANS.

History.—In June, 1898, Y. C. consulted me about an epithelioma of the penis which he and his physician friends had unsuccessfully tried to heal for eight months. Instead of healing, the epithelioma had continually grown larger until it involved not only all the preputial margin of the penis, but the larger portion of the glands as well.

Examination.—It was the squamous variety of epithelioma which had started as a warty excrescence on the folds of the prepuce. Hypertrophied papillæ studded the ulcer where the mucous membrane and skin had previously come together. Several scabs or layers of epithelium had been removed from time to time when finally the base of the growth gradually began to harden and to extend, its surface being covered with a cauliflower-like excrescence. The portions of the tumor that had ulcerated had everted edges which bled freely on manipulation. The granulations were red like a cock's comb—even the friction of the clothing or the removal of bandages was sufficient to start up a slight hemorrhage. Fortunately, the process of infection had not reached the inguinal lymphatic glands as on careful examination they were found to be neither enlarged nor tender, so it was not necessary to remove them. The fact that I had seen several epitheliomata in old people caused me to look with grave suspicion on any warty growth of the penis, even though the patient was a young man—45 years of age, as in this instance.

Diagnosis.—Though the diagnosis was self-evident, the base of the tumor hardened, and the history one of an epitheliomatous growth, the base and every indication pointing to the diagnosis of skin cancer, still I would not amputate such an important organ without first excluding every possibility of doubt of syphilitic gummata or simple papillomata. I therefore excised a small portion of the tumor and had the diagnosis of epithelioma verified by a competent microscopist. Had I not known that the patient had never been infected with syphilis, I should have tried him for a short while on large doses of iodid of potash and mercury. Chancroid is usually a more acute affection than epithelioma, is amenable to proper treatment and, as a rule, occurs in younger men. Buboes and secondary symptoms develop in the early course of syphilitic chancre, and induration is much larger in comparison to the size of the ulcer than in epithelioma. In chancre in from six to eight weeks there is a roseolous rash. In syphilitic gummata the growth is much more rapid and the ulceration after it develops is not so likely to bleed. Its edges are more undermined, its granulations not so fungous. Epithelioma, as remarked before, is usually a disease of middle or old age. It is a chronic ulcer with indurated edges and no disposition to heal, and glandular enlargement comes late in the course of the disease. All these diagnostic points should be taken into consideration, as was done in this case, before a final amputation is made. A competent microscopist can settle the question by a careful examination of a section of the tumor.

Treatment.—As the prognosis of the disease is always grave, I told the patient after the diagnosis had been made positively that the disease would progress from bad to worse and that there was no hope for recovery from local or constitutional treatment, and that his only chance would be immediate removal of the organ. He had heard the siren tale of all the quacks; in fact, he had tested some of their wares at enormous expense and pain to himself, only to see the disease progress with more rapidity than before; hence he was reconciled to radical and rational treatment, and when I assured him that the element of pain would not enter into the case at all he readily consented to an amputation of the organ, which was done in the following manner:

Operation: The pubis and scrotum were shaved and thoroughly cleansed with soap, water and the usual antiseptics. The mechanical cleansing had been done previously. The head of the organ was thoroughly hooded so as to prevent the possibility from infection from the ulcer during the operative proceedings. A strong rubber band was rendered aseptic, doubled on itself, and thrown around the penis, close to the symphysis pubis. The penis was firmly held, though not stretched, and after a cuff of healthy skin had been dissected back the cut was made through the corpora cavernosa about two inches proximal to any evidence of the diseased tissue and a beveled incision made which left the urethral portion one inch longer than the corpora; the diseased portion was thus ablated. At this point the rubber band was loosened and four small vessels were either twisted or ligated with catgut. The urethra was split up for a small distance and its edges stitched to the skin, which had previously been approximated over the amputated stump of the penis. A soft rubber catheter was left in the bladder in order that the wound might not become infected by the urine passing over it. A light sterilized gauze dressing and T bandage were applied to the perineum. The parts were occasionally washed off with boracic acid or carbolic acid solution.

Result.—An uninterrupted recovery was the result and no recurrence of the trouble has appeared, though seven years have elapsed since the operation was performed.

Remarks.—In neglected cases in which the disease has progressed even to the roots of the penis and in which the inguinal glands are enlarged, it becomes necessary to enucleate the glands from the groin as well as to amputate the penis from the symphysis pubis; as a matter of course this is a much more serious operation and the liability to recurrence is much more probable. Castration of the patient at the time this amputation is done has been advocated by some surgeons, but as the operation is required at an age in which sexual passion rarely enters into the case, it occurs to me that the testicles may be left unless they too are involved in the diseased process.

INTESTINAL PARASITES IN CANAL ZONE.

ONE HUNDRED AND FIFTY CONSECUTIVE EXAMINATIONS OF STOOLS.

NORMAN E. WILLIAMSON, M.D.
Pathologist, Colon Hospital,
CRISTOBAL, CANAL ZONE.

Balantidium coli, or *Paramœcium coli*, has not hitherto been reported from this section. It occurred in two cases of our short series. It has also twice been seen by Dr. E. P. Beverley, and in one case by Dr. Lloyd Noland, at Ancon Hospital—five cases in all.

It is oval or pear-shaped, at times round; from 70 to 110 microns in length by from 60 microns to 72 microns in width. It is actively motile, being covered with flagellæ most numerous at the mouth, which is at the small pole. There are a rather large nucleus and two contractile vacuoles.

Intestinal Parasites Found in 150 Consecutive Examinations of Stools.

	Ova of Uncinaria Duodenalis.	Ova of Tricocephalus Dispar.	Ova of Ascaris Lumbricoides.	Ameba Dysenterie.	Rhabdonema Strongyloides.	Cercomonas Intestinalis	Balantidium Coli.	Myiasis.	Trichina Spiralis.	Negative.

A monograph of reported cases has recently been written by R. P. Strong. Access to more recent literature is not available here.

The two cases seen here were complicated by other infections. Both patients, however, had diarrhea, which could be attributed to the balantidium, which was found in great numbers in both cases.

Worthy of note also is the relative frequency of *Rhabdonema strongyloides.* The small, yellow, slowly motile ameba, which I have frequently seen in the Philippines, and which is usually considered non-pathogenic, has not been seen in this series of cases.

A CHRISTMAS STORY.

E. S. McKEE, M.D.
CINCINNATI.

About eighteen years ago I was called to see a patient, a recent arrival from Russia, whom we will call Mrs. Blankstein. She was very ill, indeed, and I found it necessary to see her every day for a month, commencing December 15. She recovered, and in due time I sent my bill. In somewhat overdue time her husband came to my office to pay it. The following was his plea: "Mr. Doctor: dat bill you zendt mein vife, he's all dright, but vone dem visits you make mein vife you makes him on a *Grisdmas* day, and I vandt you make me a bresent dat visit you makes mein vife ond Grisdmas day." The request was so original, coming from the source it did, so different from the usual demand of a per cent. off, that I threw off the visit, made him a "bresent" of it, instead of charging him double as I felt like doing for being taken away from my Christmas turkey.

I have had many times the worth of the presented visit telling it to my friends. Almost every Christmas since this occurrence I have been called to some sufferer, poor in this world's goods, and before leaving I have told the story of the Christmas present of a visit and made the patient a present of the Christmas visit I was then making. The happy smile, the brightened eye of the pale patient has been my reward for working when the rest of Christianity was feasting.

SATURDAY, DECEMBER 23, 1905.

ACCIDENTS AND THE DUTY OF THE STATE.

We all have a hazy understanding that there are too many industrial and other accidents in this country. We realize indistinctly and shudder sympathetically over those appalling federal statistics as to railroad accidents which have convicted us before all Europe of reckless disregard of human life. Indeed, we seem to accept the accident column as a natural accompaniment of our breakfast. It is a permanent feature of the daily papers, though its proportions tend to shrink as the material monotonously increases, so that the death of an obscure person by street-car accident is now not worth more than an inch of type. Yet, in fact, we are all curiously ignorant as to the actual extent and portent of accidents. We have no knowledge of the numbers of non-fatal accidents nor of the disability which results from them, and our only trustworthy figures as to fatal accidents are those concerning railroad accidents and to some uncertain extent accidents in mines. We do know from German statistics that the greatest burden of accidents is borne by certain classes of manual workers: such occupations as those of diggers, teamsters, sailors, miners—occupations in which the man must depend on his own personal strength—are those showing the heaviest proportion of disabling accidents. Recent statistics[1] only confirm the observation of those familiar with the accident wards of our great hospitals. Their occupants belong on the whole to the humblest ranks of the industrial army, and death or disabling injury means in their case usually the reduction of themselves and their families to pauperism. Physicians who have served in such wards will recall many instances of patients technically cured, yet evidently incapable of returning to their former work. The subsequent history of such cases, the long-delayed convalescence, the resulting dependency and even pauperism have never been reckoned up, yet it is the public which must bear the expense of the patient through his hospital treatment and the public which, in many cases, must support him and his family after he leaves the hospital.

Whether it could ever be considered the function of a public hospital to inquire into the nature and causes of the accident cases in its wards is, of course, open to question; yet there can hardly be a question but that the public which pays for the costly hospital service, and in many cases for the maintenance of the family, may properly ascertain through some agency where the responsibility for a given accident actually rests. At present, this work of investigation and of fixing responsibility is not only ignored by the public, but because of public neglect the whole matter has fallen into the hands of exploiters on every side. First, there are the great corporations which maintain private hospitals and impregnable secrecy. Second, there are the employers' insurance associations, which secure the individual employers against the third element, "the personal inquiry lawyer" and his indispensable colleague, the "ambulance shark."

The employer does indeed seem forced to use this expedient of insurance, which relieves him of the costly annoyance of defending suits reasonable and unreasonable, but which at the same time cuts him off from the friendly sense of responsibility for men injured in his service—a responsibility he would naturally both feel and express. The workman, on the other hand, by means of this employers' insurance, is prevented from dealing with his employer directly, and as he has no money with which to pay lawyers', physicians' or court fees, he is driven to practitioners who will accept his case on shares. The patient is really the victim at every point of circumstances over which he can never hope to exercise control. He bears the penalty of the law's delays and sets his puny strength against that of highly organized business enterprises. If after years of waiting he obtains adequate damages, he must content himself with but the share of the monkey in the old fable.

The governmental insurance of Germany shows the first successful effort to bring some sort of order out of this chaos. It has been now a matter of twenty years' experimentation there, and the results are worthy of study. We have not space to give more than the merest outline of the system now in operation in Germany, and already extensively imitated in Austria and other countries. There are already three forms of compulsory insurance established, against sickness, accident and old age. The insurance funds against sickness are contributed one-third by the employers and two-thirds by the employes, accident insurance is a charge against employers only, while the old age or disabilities indemnity is made up of about equal contributions from the employers and the employes, supplemented by a small fixed contribution by the government. These various funds are managed under strict governmental supervision at an astonishingly small expense. The administration charge is stated as less than 8.5 per cent. Embezzlement and misappropriation are unknown. The annual receipts are more than $130,000,000, and 17,000,000 work men and women are contributing to and receiving these funds. It is, however, to the accident insurance and its direct and incidental results that we wish to refer. The following points are especially to be noted: 1, All manner of safeguards of life and limb have been introduced by employers of the various insuring groups;

---

[1] "Statistisches Jahrbuch für das Deutsche Reich," 1903.

2, hygienic conditions in places of employment have greatly improved; 3, all possible methods of treatment tending to shorten the period of convalescence after accident and to restore the working power of the patient have been introduced into the hospitals; 4, country convalescent homes have been greatly developed. It is true that superficially there appears to be in Germany a large increase in the number of accidents; that, however, is acknowledged to be due to the fact that all accidents, however slight, are now reported, and a man with a cut finger is sent to a physician. The serious complications which may follow neglect of trivial hurts is thus avoided by prompt attention.

Thus the public does not cease to enforce the employers' responsibility for the injured man until the latter is restored to active labor. The United States is the only great civilized country which continues a wasteful *laissez-faire* policy toward industrial accidents. Russia's new law enforces the employer's responsibility in a way second only to that of Germany, and in like manner France, Belgium and even England have laws which recognize the inevitable powerlessness of the workman to protect himself from the dangers of his occupation.

Doubtless it will be long before we shall see in this country any system of compulsory insurance. Indeed, the very suggestion is repugnant to the average American. Yet no candid observer, least of all any physician of large hospital experience, can doubt that the whole subject of industrial and trade accidents needs examination and publicity and some intelligent and authoritative supervision.

DRUGS AND DIET AND MIND AND STOMACH.

In the deluge of new drugs that has come on the medical profession during the last decade nothing has been more remarkable than the number of remedies suggested for gastric affections. Surely if it were possible to relieve gastric symptoms by drug treatment some one or more of the many remedies offered to the profession would have proved successful. The mineral, the animal and the vegetable kingdoms have been diligently searched and put under contribution to supply therapeutic substances. From the silver and gold which were much more recommended as gastric tonics a decade ago than they are now, down to the almost innumerable forms of ferments of all kinds which have been suggested there has been a veritable flood of remedies for dyspepsia. It has been found in most cases that any one of these remedies if given with proper suggestions as to its efficacy and, if the patients were curiously inquisitive, with added details of information as to its source, would do good for a time at least, though inevitably before long the therapeutic effects ceased to be obtained.

There has come to be a rather general impression, then, that most of these new-fangled gastric remedies, except for a certain amount of tonic stimulation, which their composition always assured for them, owed most of their beneficial effect to the influence on the patient's mind of a new form of drug treatment. In a word, there has come to be a suspicion at least that in this as in the many tonic remedies of less ethical pretentions the only therapeutic effect directly produced has been that of the stimulant, while the supposed specific efficacy was due to mental influence. It has become more and more clear in recent years that a large number of persons—in the words of a distinguished London physician—have not enough brains to run their business and their digestion. If their brains are occupied most of the day with intellectual affairs of any serious kind this is especially sure to be the case. It is the people of the educated classes who know that they have stomachs, who are constantly pestered by the subjective symptoms which that organ gives and who are looking for remedies and modifications of diet that will save them from further annoyance.

There is no doubt that, while their minds are open to receive them, new suggestions often prove of therapeutic benefit, but these suggestions are also to no little extent responsible for the dyspeptic symptoms of which the patients complain. Too much attention is paid to the stomach and its functions, and as a consequence it does not get on well. The centipede, when asked how he could possibly walk with all his legs without getting them confused, is said to have tried to explain how it was done, but got so mixed up that he lay absolutely unable to move. Something of the same thing seems to be true with regard to these dyspeptic patients who nurse their ailments and know all the dietetic rules, especially with regard to getting up from the table hungry, not taking liquids with meals, avoiding certain foods because they have an idiosyncrasy for them, and all the other details whose safeguarding must require such an intense attention at meal time as sadly to demoralize the trophic influences flowing down from the central nervous system.

Long ago, in the early forties, Prof. Austin Flint, the elder, insisted on this connection of dyspepsia with the mind, and then nearly half a century later, in an article[1] read before the New York State Medical Association, called particular attention to the fact that his experience as a physician had completely confirmed the ideas expressed in his original paper. He insists especially that the most important direction that can be given to dyspeptics is to avoid thinking too much about themselves, about their symptoms, their diet, their personal peculiarities as to food and the like, and to tell them frankly that they should not follow so-called rules of health in this matter, but should consult their tastes and their appetites.

He said in a passage which should be in the notebook of every physician: "Do not adopt the rule of eating only at stated periods; twice or thrice daily. Be governed in this respect by appetite and eat whenever there is a desire for food. Eat in the morning or at bedtime, if food is desired. Insomnia is often attributable to hunger. In the choice of articles of diet be distrustful of past personal experience and consider it to be a trustworthy rule that those articles will be most likely to be digested without inconvenience which are most acceptable to the palate. As far as practicable let the articles of diet be made acceptable by good cooking. As a rule, the better articles of food are cooked, the greater the comfort during digestion. Never leave the table with an unsatisfied appetite. Be in no haste to suppose that you are separated from the rest of mankind by dietetic idiosyncracies and be distrustful of the dogma that another man's meat is poison to you. Do not undertake to estimate the amount of food which you take. In this respect different persons differ very widely, and there is no fixed standard of quantity which is not to be exceeded. Take animal and vegetable articles of diet in relative proportions as indicated by instinct. In the quantity of drink follow Nature's indication, namely, thirst. Experience shows abundantly that, with a view to comfortable digestion, there need be no restriction in the ingestion of liquids."

---

[1] Transactions of the New York State Medical Association, vol. I, p. 143.

There seems to be no doubt that if this common-sense method of dealing with these frequent and bothersome patients who usually want to take so much time in explaining their idiosyncrasies should be more generally followed we should hear much less of the multitudinous stomach remedies and especially of the far-fetched ferments of whose efficacy there is *prima facie* doubt, though they come lauded with all the alluring pseudoscience of the professional advertising agent. Along this line lies peace and progress for both physician and patient. With intestinal function carefully regulated, it is not digestive specifics, but freedom from worry and a return to pristine habit and instinct that will restore dyspeptics to their place among those with *mens sana in corpore sano.*

THE TREATMENT OF BACTERIAL DISEASES BY VACCINES.

The discovery of the diphtheria antitoxin at the end of the last century gave rise to hopes regarding the treatment of other bacterial diseases, which were soon dashed to the ground. In the years succeeding the discovery of diphtheria antitoxin, a mass of facts bearing on the general subject of infection was collected, and bacteriologists soon realized that bacteria secreting so-called exotoxins were very much in the minority. Most of the bacterial infections to which the flesh is heir are due to germs which produce endotoxins which cannot be combated by the methods used against diphtheria, botulism and tetanus. In his introduction of tuberculin, Koch was the first to suggest a procedure having in view the destruction within the body of an endotoxin-producing organism, the tubercle bacillus. The failure of this treatment, under Koch's own method of administration, is known to all, and has led to its almost complete abandonment.

Some three years ago A. E. Wright, in England, suggested what was a modification in the method of administration, rather than a modification in the principles of manufacture of bacterial vaccines. Wright's work, however, was based on some new observations on the protective mechanism of the human body, in that it was preceded by the discovery that besides antitoxins and other reactive substances, the blood serum normally contains protective bodies which Wright called opsonins. These opsonins, which seem to be present in normal individuals in an almost equal quantity, are reduced before or in the early stages of a bacterial infection, and vary greatly during the course of a bacterial disease. The method of treatment which has been applied to diseases produced by bacteria having endotoxins, such as the *Bacillus typhosus,* has usually been that of inoculation with a vaccine composed of the dead bodies of the bacteria and their soluble products. Hitherto such inoculations have not been based on any accurate method, the dose has been gauged empirically, and the administration has been rather a haphazard performance. The work of Wright has shown that under such methods it was just as easy to do harm to the patient as to benefit him, perhaps a little easier. Wright and other workers, such as Bulloch,[1] have shown that there are times during a bacterial infection when the system is not manufacturing opsonins in normal quantities, and, on the other hand, there are times when large amounts of opsonin are being produced. According to Wright, the manufacture of opsonins, or antitropins as he now calls them, follows a definite law. He calls this the law of the ebb, flow and reflow, and subsequent maintained high tide of immunity. If a patient with a given bacterial disease, say for example, tuberculosis, is inoculated with tuberculin during the ebb in antitropin formation, the result is an actual increase in the poisoning of the individual, and naturally an increase in the severity of the symptoms. If, on the other hand, the individual is inoculated at a time when the system is producing large numbers of antitropins, i. e., during the flow, the inoculation stimulates the system still further to the production of antitropins, and the result is the improvement of the patient.

So far Wright has applied his method mainly to two conditions: tuberculosis and staphylococcus infections. The results of his treatment have been exceedingly encouraging. Most of his work has been done on patients who had been given up after the utter failure of ordinary treatment, and the percentage of cures and improvements is quite high. The method is in many ways quite complicated, requires for its carrying out a laboratory, and needs the supervision of one who has had experience in the work. It is a form of treatment which will almost of necessity fall into the hands of the large hospitals, and which can never be carried out by the general practitioner. So far but little practical work has been done outside of London, where Wright and his associates have worked, but the treatment promises so much, and if successful, will be applicable to so many diseases, that it is to be hoped that it will be given an extensive trial.

---

MAGNESIUM SULPHATE AS AN ANESTHETIC.

Few greater boons have been conferred on humanity than that which has resulted from the discovery and application of ether and chloroform as anesthetics. America may well be proud of the part that has been given to her to play in this matter, and if we read the indications aright further honor is to come to her for new and important discoveries of scarcely less magnitude. The American mind has shown itself to be an eminently practical one, but it is none the less scientific. It is practical because its discernment is clear and its reasoning correct—and science is but applied precision.

The latest exemplification of the foregoing statements is found in the results of a series of experiments carried on by Dr. S. J. Meltzer in association with Dr. John Auer and reported at a recent meeting of the New York Academy of Medicine.[1] These investigators were able to demonstrate the possession by magnesium-salts of hitherto undescribed inhibitory and anesthetic properties susceptible to therapeutic application. Dr. Meltzer had formulated the view that the phenomena of life result from the interaction of excitation and inhibition. Of the four main inorganic constituents of the body it has been shown that sodium, potassium and calcium have a stimulating effect on muscle and nerve. It was, therefore, concluded that the inhibitory activity must reside in the magnesium, and accordingly a study of the salts of this body was undertaken. It was found in animals that intracerebral injections of magnesium sulphate induce a state of general inhibition. It was next discovered that intravenous injections of various magnesium-salts in small amount inhibit respiration and cause paralysis of the entire body; that local applications to nerve-trunks blocked conductivity and abolished excitability; that subcutaneous injections cause deep narcosis, with complete muscular relaxation, while subarachnoid injections cause almost immediate anesthesia and paralysis of the posterior extremities. In addition it was found that intravenous injections of magnesium-salts almost instantly check intestinal peristalsis, while severe tetanus and opisthotonos induced in monkeys by tetanus-toxin can be completely removed for many hours by subcutaneous injection of magnesium sulphate.

The several procedures mentioned having proved innocuous in animals it was decided that they might be applied to man with safety. Accordingly, twelve patients were given intraspinal injections of magnesium sulphate prior to operation at the hands of several surgeons. It was found that the best amount to employ is one cubic centimeter of a sterile 25 per cent. solution to every twenty-five pounds of body weight and the best time for operation is three or four hours after the injection. The effects observed consisted in paralysis of the legs and of the region of the pelvis, with analgesia sufficient to permit surgical operations. Larger doses give rise to profound general anesthesia, with marked depression of respiration. There is also retention of urine, which may persist for one or two days. Sensibility and motility return as a rule within from eight to fourteen hours.

It is not likely that intraspinal injections of magnesium-salts will replace inhalation of ether or chloroform for purposes of surgical anesthesia, but there are times when the latter cannot be practiced with safety, and although the former is not wholly free from risk, it has advantages over other forms of intraspinal anesthesia, and it may be found that it is susceptible of application under the circumstances mentioned. In any event the method is worthy of careful trial.

RECOGNITION OF MEDICAL ORGANIZATION.

In New Orleans there is a popular movement in favor of permitting the Louisiana State Medical Society to nominate the president of the State Board of Health. The Governor, who has the appointing power, has not yet announced his position toward this proposal, but all classes of citizens in New Orleans seem to favor the innovation. This can only be regarded as a genuine recognition of the altruistic services of the medical profession to the community and as an expression of confidence in the purposes and principles of medical organization. We shall hear more of this sort of thing as organization proceeds and fulfills its proper duties.

SUICIDE AND SELF MANSLAUGHTER.

A person who is supposedly sane and who sacrifices his life through willful neglect—whether this be due to pride not permitting him to ask for help or to religious delusions forbidding him to take the needed measures for his preservation—is little different from an ordinary suicide. The London coroner at Rotherhithe, however, makes a distinction. A man had deliberately refused to seek medical aid on account of his belief in faith-healing, and the coroner instructed the jury that since there was no evidence that the man had refused medical advice with the sole object of ending or shortening his life, the verdict could not be suicide by omission or self-neglect. It was, therefore, not a case of self-murder but of self-manslaughter—an offense not recognized in the criminal code. There is a distinction here with a difference, if the man really believed he was going to get well by faith alone, spurning all material aid thereto, but it is hard to see how the criminal law can safely consider such proceedings as without its pale. There seem to us to be large possibilities for evil in such a course. So far as the results to society and the individual are concerned, there is little difference between such a course and suicide, and the law is for the protection of society and the individual. When it comes, moreover, to the aiders and abetters of such transactions, no matter what are claimed to be their motives, it does seem as if the law should have power to intervene, especially when they attempt to apply their principles to the irresponsible and helpless. We must remember also that suicide does not itself always imply moral obliquity. A very large proportion of suicides are clearly irresponsible, and the degree of responsibility in many others is difficult to decide. The distinction, therefore, between self-murder and self-manslaughter seems to be rather a vague one, and we believe it would be better for the community if a coroner's verdict of suicide or homicide by neglect were brought in every case of avoidable death under Eddyism, faith cure and similar methods.

[1] Medical Record, Dec. 16, 1905, p. 965. See abstract in The Journal, December 30.

BIRTH RATES.

It is a well recognized fact and needs no verification that the poor are more prolific than the rich; the reasons are also well known. According to the *New York World* of November 30, out of 55,000 babies born in the borough of Manhattan only 13 came to fashionable Fifth avenue below Ninety-fifth street. That is only 13 babies in a thoroughfare bordered by the homes of the well-to-do for four and one-half miles. The contrast between these figures and those of the populous sections inhabited by the proletariat is certainly striking enough, and we must think that there are some elements in the statistics that are perhaps deceptive. New York is in the registration area and the figures ought to be correct, but it seems to us as possible that many of the offspring of the rich New Yorkers may be born away from home and thus affect the figures.

THE PRECIPITIN TEST FOR HUMAN BLOOD.

The importance of the precipitin test in determining biologic relationships has been clearly set forth in Nuttall's fine monograph on the subject, and it must be admitted that the facts there instanced certainly tended to diminish the value of the test from a medicolegal standpoint. The relationship between man and the ape, for example, is shown by the fact that the serum of a rabbit inoculated with human blood gives a precipitate not only with human blood, but also, though in less degree, with the blood of the ape. The precipitation of an immune serum by the blood of allied species as well as by the specific blood used for inoculation is a circumstance that naturally prevents the formulation of any such dogmatic statement as seems required by the exigencies of the law. Uhlenhuth's[1] discovery, however, seems to remove this difficulty. The inoculation of rabbits with the blood of the closely-related hare gave rise to a serum which precipitated when mixed with hare's blood, but had no action on the blood of the normal rabbit. Similarly apes inoculated with human blood produced a serum that had high precipitating power for human blood, but was inactive for apes' blood even in low dilution (1:10). These results are somewhat at variance with those obtained by other observers who have found it difficult to produce potent antisera with the blood of closely-allied species. Uhlenhuth explains this, however, by individual idiosyncrasy in the experiment animals, and considers that while some individuals may not lend themselves readily to the production of antisera with the blood of kindred species, others are favorable for this purpose. If his results are confirmed it is evident that when sera produced by this method are used the value of the precipitin test in legal medicine will be greatly enhanced.

THE PATHOLOGIC ANATOMY OF EXOPHTHALMIC GOITER.

So many and such varied anatomic conditions have been found in connection with exophthalmic goiter that it is not easy to decide which are essential and distinctive and which non-essential and accidental. The most common of these consists in certain histologic alterations in the enlarged thyroid gland, to whose overaction the principal symptoms of the disorder appear to be due. Such alterations were found with great frequency by Dr. W. C. Mac Callum[1] in a series of 28 cases studied histologically. They involved the form and size of the alveoli, the character of the epithelial cells, and of the colloid, the vascular supply, the connective-tissue framework and the lymphoid structures of the thyroid gland. The alveoli vary greatly in size and form, the epithelium of many being folded in such a manner as to yield an appearance of sending off long diverticula, which frequently become constricted off and form new alveoli. The epithelium changes from a flat or cubical type to the high cylindrical form. The colloid is markedly diminished in amount and presents a ragged appearance. The vascular supply is extraordinarily rich, the veins being especially large and distended with blood. The latter lie for the most part in the abundant connective-tissue framework of the gland, which is increased in density, considerable bands of fibrous tissue passing through the gland and giving rise to distinct lobulation. The walls of the veins are unduly friable and the connective tissue contains a good deal of lymphoid tissue in the form of circumscribed scattered nodules. In addition circumscribed prominent nodules, composed of a more homogeneous tissue are found in varying number. These are made up of uniform, small, round alveoli, usually separated one from another and embedded in a hyaline connective tissue. They are lined with plump, rather cubical, epithelium, and they may or may not contain colloid material. Cysts of varying size, usually containing a clear greenish, somewhat glutinous, fluid, are also present at times. No bacteria or cell inclusions could be demonstrated and the parathyroid glands were found practically normal in the nine cases in which they were examined. The anatomic picture, it will be seen, corresponds most closely with that of compensatory hypertrophy, which it may be presumed has followed a previous injury to the gland inflicted perhaps by some infectious disease.

Medical News

CALIFORNIA.

Sanitarium Opened.—Loma Linda Sanitarium, near Redlands, was opened to the public October 1 under the management of Dr. George K. Abbott. It is operated under the methods of the parent institution in Battle Creek, and its régime includes all branches of physiologic therapeutics.

October Vital Statistics.—The returns from 53 out of 57 counties for October show an annual birth rate of 13.1 and an annual death rate of 14.9 per 1,000. During the month 1,873 living births were reported, and 2,117 deaths, not including stillbirths. Tuberculosis was the leading specific cause of death in the state, but of those who died from the disease 11.4 per cent. had lived in the state less than one year.

Personal.—The Point Richmond Board of Health met November 23 and elected Dr. Hawley N. Barney health officer.——Dr. Louis C. Deane, San Francisco, has gone to Germany.——Dr. D. C. Strong, Redlands, has assumed his duties as superintendent of the San Bernardino County Hospital.——Dr. H. Miller Robertson, Arlington, has been elected county physician of Riverside County, vice Dr. Isaac A. McCarty, Corona, resigned. ——Dr. Warren T. Barr has been appointed a member of the Fresno health board vice Jacob H. Parseghlan, resigned.—— Dr. William H. Brooke has resigned as a member of the Alameda board of health on account of removal from the city.—— Dr. Lewis Q. Thompson, Gridley, is seriously ill with septicemia.

GEORGIA.

Insanity Among Negroes.—Dr. T. O. Powell, superintendent of the Georgia State Sanitarium, Milledgeville, is reported as saying that there are 900 negroes now at the State Hospital and that many more are awaiting admission.

Personal.—The governor on December 5 reappointed Dr. Charles J. Montgomery, Augusta, and Dr. William F. Brunner, Savannah, as members of the trustees of the Georgia State Sanitarium, Milledgeville.——Dr. Thomas P. Waring, Savannah, was operated on December 2 for appendicitis and is making satisfactory progress.——Dr. Owen T. Kenyon, Dawson, shot and killed R. E. Dickinson in Atlanta, November 25, in self-defense. No charge was preferred against Dr. Kenyon.

IDAHO.

Epidemic Diseases.—Diphtheria is prevalent to such an extent at Burke that the public schools have been ordered closed and public meetings prohibited.——The publication committee of the Boise Medical Society has issued a circular denying the rumors that typhoid fever is epidemic in the city and stating that the disease is sporadic and that in fully one-half of the cases it was contracted outside of the city.

Society Upholds Dr. Nourse.—Dr. Robert L. Nourse, Hailey, has been fined $300 and costs for contempt of court because of language used in his address before the Idaho State Medical Society, criticising the action of the Fourth Judicial District Court in the case of Dr. Raff against the Idaho Board of Medical Examiners. Dr. Nourse is supported by the state medical society and will make application for a writ of review.

ILLINOIS.

Reappointments.—Dr. Vaclav H. Podstata has been reappointed superintendent of the Cook County Institutions, Dunning, and Dr. Haim I. Davis, county physician.

Smallpox.—Several cases of smallpox have appeared in Jersey, Greene and Macoupin counties, and on December 17 reports were received of the appearance of the disease at Galesburg and Spring Valley.

For a Visit Only.—Dr. Lemuel Tibbetts, Rockford, requests the correction of the statement in The Journal that he was about to move to California. He expects to visit California for two or three months, leaving about the middle of January.

Physicians Vindicated.—In the case of Dr. Joseph R. Hollowbush, Rock Island, charged with perjury by Jerry McCarthy, the state's attorney authorized the dismissal of the case, completely vindicating Dr. Hollowbush.——After a trial occupying ten days the jury in the case of C. E. Demsey against Dr. St. Elmo M. Sala, Rock Island, for damages on the charge of alleged malpractice, returned a verdict for the defendant.

Coroner's Cases.—The coroner of Cook County in his annual report shows that 3,482 cases were investigated in his office since Dec. 1, 1904. Of this number 1,185 deaths were from natural causes and 453 were suicides. Of the latter 159 died from gunshot wounds, 83 from asphyxiation, 11 by jumping from heights, 20 from drowning, 2 from setting fire to clothing, 26 from cutting or stabbing, 6 from jumping under trains, 43 from hanging, and 103 from poisoning.

Dedication of Ottawa Tent Colony.—On December 12 the Tent Colony for the Treatment of Tuberculosis, Ottawa, was formally dedicated. Dr. Frank Billings, Chicago, made the principal address, in which he told in plain terms the latest decision of science regarding the treatment of tuberculosis, and eulogized Dr. James W. Pettit for his work in the cause of humanity. Two years ago the state medical society authorized Dr. Pettit to make this experiment at his own expense. In closing, Dr. Billings said the greatest work that Dr. Pettit has done has been to humanity in general by setting a great living example of right living to all the world, "and these things I say not in flattery, but in envy of the great work that Dr. Pettit has been permitted to do at a great sacrifice to himself." Dr. George A. Zeller, superintendent of the Illinois State Hospital for the Incurable Insane, Bartonville, in his address, praised Dr. Pettit for reducing the per capita cost for the care of tuberculous patients and stated that the modern method of treating tuberculosis was being followed as far as possible in the state institutions. A buffet luncheon was served at the club house and public exercises were held in the pavilion.

Chicago.

Deaths of the Week.—During the week ended December 16, 489 deaths occurred, equivalent to an annual death rate of 12.80 per 1,000, which is nearly 12 per cent. less than the rate of the previous week and the rate of the corresponding week last year, 15 per cent. less than the average December rate of the last decade and 1 per cent. less than the lowest previous recorded rate. Of the deaths 81 were due to pneumonia, 60 to consumption, 35 to nephritis, 33 to violence (including suicide), 32 to cancer, and 30 to heart disease. One death was caused by scarlet fever, 11 by diphtheria, and 4 by typhoid fever.

INDIANA.

Golden Wedding.—Dr. and Mrs. T. B. Noble, Greenwood, celebrated their golden wedding anniversary November 30.

Medical Faculty Entertained.—The University Club of Purdue University entertained the faculty of the Purdue School of Medicine, Indianapolis, at the Hotel Lahr, Lafayette, December 9. President W. E. Stone of Purdue University officiated as toastmaster. Drs. George Kahlo, Indianapolis; Christian B. Stemen, Fort Wayne, and Myles F. Porter, Fort Wayne, responded to toasts.

Laboratory Instruction.—At the health officers' school, held in Indianapolis under the direction of the State Board of Health, December 14 and 15, instruction was given in the work of the pathologic and bacteriologic divisions of the State Laboratory of Hygiene, including demonstration of the Widal test, diphtheria cultures, tubercular bacilli, bacteriologic analysis of water, preparation of specimens for shipment, methods of obtaining analysis from the laboratory, and general laboratory procedure.

Personal.—Dr. William B. Fletcher, Indianapolis, was seized with cerebral hemorrhage December 11, and is critically ill.—— Dr. John M. Nickels, Sellersburg, has been appointed physician for the poor farm of Clark County, succeeding Dr. Charles M. Bottorff, Charlestown.——Dr. Brose S. Horne, Marion, has located at Jonesboro.——Dr. Albert H. Combs has been appointed a member of the health board of Marion.——Dr. Frank G. Jackson has resigned as a member of the Muncie board of police commissioners.——Dr. Samuel E. Smith, superintendent of the State Hospital for the Insane, East Haven, has been appointed expert advisor to the Southeastern Hospital commission.——Drs. Edmund D. Clark, Thomas B. Noble and Frank A. Morrison have been appointed the board of health of Indianapolis.——Dr. Norman E. Jobes has been appointed superintendent of the City Hospital, Dr. Eugene Buehler city sanitarian, and Dr. Edgar F. Kiser superintendent of the city dispensary.——Drs. John C. Wood and Roscoe W. Payne have been appointed members of the Franklin board of health.—— Dr. Frank W. Black, Ligonier, has been appointed coroner of Noble County.——Dr. Irvin J. Becknell, Goshen, has been appointed secretary of the Elkhart County board of health.

IOWA.

Fire Loss.—The residence of Dr. Cassius C. Cottle, Marshalltown, was destroyed by fire November 27, with a loss of $12,000.

Typhoid Fever.—Typhoid fever has assumed an alarming proportion at Estherville. Four deaths occurred in one day last week.

In Fashion.—Des Moines is being visited with an epidemic of grippe, with the neuralgic symptoms recently reported to be prevalent in London.——Sioux City is said to be suffering from a similar epidemic.

Illegal Practitioner Fined.—Dr. J. C. Wilhite, who was convicted November 25 of the illegal practice of medicine, was sentenced to pay a fine of $300 and costs. Wilhite says he will appeal to the Supreme Court.

Personal.—Dr. Benjamin O. Kittleman, Des Moines, was operated on for tuberculosis, December 3, and is making a good recovery from the operation.——Dr. Nicholas Schilling, New Hampton, sailed for home from Naples, December 8.——Dr. Henry C. Young, Bloomfield, was operated on for appendicitis, December 3, and is doing well.——Dr. George M. Kline, Mount Pleasant, has accepted a position on the medical staff of the new State Hospital for the Insane, Ann Arbor, Mich.

KANSAS.

Personal.—Dr. James A. Trowbridge, La Harpe, expects to leave early in January for Europe.

Donation to Hospital.—Dr. Simeon P. Bell has added $20,000 to his donations to the Kansas University Hospital, Rosedale, making a total of $90,000, including the site on which the medical buildings are erected.

Diphtheria.—Yates Center has had 3 deaths from diphtheria. Five residences are under quarantine and schools and other public meeting places have been closed.——During October there were 364 cases of diphtheria reported in the state, with 41 deaths, an increase of 140 over September and an increase of 30 in deaths. The disease is said to be prevalent in 33 counties.——Quarantine measures are being enforced in Oakland.——The schools in Toronto and in Neal have been closed.

Physicians and Political Appointments.—Kansas physicians believe that in the interest of the public welfare the State Medical Society should have something to say as to who should be on the State Board of Health and the State Board of Examination and Registration. The governor of the state, however, seems to think differently. The following excerpt from an editorial in the *Journal of the Kansas Medical Society* gives some idea of the situation:

> At the Wichita meeting three men from each county were selected as representatives of the profession and presented to Governor Hoch with the request that he select new men from this list. The governor saw fit to ignore us utterly, and appointed men who, doubtless on account of their relation to politicians or of their business ability, seemed to him the ideal physicians. But not one of the appointees was in touch with the modern movement in medicine, and, therefore, in spite of their personal charms, were hardly fitted to make and execute laws affecting so vitally our profession.
>
> We do not wish to mix up in politics, but it looks as if Governor Hoch were going to force us to do so. He thinks us a negligible quantity simply because we have not flocked before him and pestered his life with importunities. We evidently must change our policy and get after every politician in every county where we are organized. We can have great influence on even Governor Hoch's renomination and election. We can see to it that every new assembly man is pledged to give us the "square deal"—and to take our side against the vacillations of our Nicolaian governor. Every member will please do what he can for himself in this matter, but more especially hold himself in readiness to respond to Secretary Huffman's telegraphic or written directions.

KENTUCKY.

Medical College Opens.—The Louisville Medical College opened its thirty-eighth annual session December 10, with a lecture by Dr. Clinton W. Kelly.

Sanatorium Opened.—The new sanatorium at Hopkinsville was opened by Dr. C. B. Petrie, November 19, and on that day the Christian County Medical Society held its regular meeting in the building as the guest of the proprietor.

Railway Hospital Service Wanted.—Representative Rihnock, Covington, has introduced a bill into Congress asking for the establishment of a railway hospital service, organized along the same lines as the United States Marine-Hospital Service.

Diphtheria and Smallpox.—Diphtheria has developed at Turner's Station and Smithfield, Henry County. At the former place the school has been closed on account of the disease.——Smallpox has appeared at Middlesboro, where 48 cases are reported.——Several new cases of smallpox are reported in the vicinity of Nepton.

Kentucky Railway Surgeons Organize.—About 40 railway surgeons of the state met at Lexington, December 1, and organized the Kentucky State Association of Railway Surgeons. Dr. Richard C. Falconer, Lexington, was elected president; Dr. Clarence H. Vaught, Richmond, vice-president, and Dr. James B. Kinnaird, Lancaster, secretary and treasurer. The next meeting will be held in Richmond, June 15, 1906.

Health Officer Wins.—The suits filed against Dr. Maverell K. Allen, health officer of Louisville, by George Churchman, a dairyman, to recover $145 alleged damages for loss on milk and to recover $50 for alleged damages to the plaintiff's business, have been decided in favor of the defendant. Last summer Dr. Allen instigated proceedings against Churchman because he failed to produce a certificate that milk furnished him by a Shelby county farmer was from perfectly healthy cows, as required by the city ordinance.

LOUISIANA.

Children's Sanatorium.—A sanatorium exclusively for children is to be located at 850 Carondelet Street, New Orleans, in charge of Dr. Erastus D. Fenner.

Wish to Name State Health Officers.—At a meeting of the governing committee of the New Orleans Health Association, December 5, the following resolution was adopted: "*Resolved*, That it is the sense of this association that the nomination for state health officer be made from the recommendations of the State Medical Society."

Personal.—Dr. Arthur Weber has resigned as a member of the New Orleans Board of Health.——The Shreveport Medical Society on December 6 adopted a resolution indorsing the selection of Dr. Clifford H. Irion, Benton, for president of the State Board of Health.——Dr. J. Ashton Blanchard, Shreveport, has been indorsed for appointment as a member of the State Board of Health by Dr. T. E. Shumpert, a majority of the city council and 25 members of the local medical fraternity.

MAINE.

Released.—Dr. Charles A. Eastman, Old Orchard, convicted of manslaughter a year and a half ago, completed his sentence in the county jail and was released November 29.

Medical Club Meets.—The twenty-eighth annual meeting of the Portland Medical Club was held December 7, at which the following officers were elected: President, Dr. Herbert J. Patterson; vice-presidents, Drs. Chauncey R. Burr and Owen Smith; secretary and treasurer, Dr. George H. Turner, and censors, Drs. Stanley P. Warren, Walter D. Williamson and F. P. Webster.

Fight Smallpox.—In order to prevent the introduction of smallpox from New Brunswick into Maine the State Board of Health has established a provisional inspection service at Vanceboro under the care of Dr. Melvin L. Young, and has petitioned the surgeon general of the United States Public Health and Marine-Hospital Service to establish a permanent station at Vanceboro.

General Hospital Report.—The fourteenth annual meeting of the Central Maine General Hospital Association, Lewiston, was held December 5. The number of patients treated during the year was 1,127, an increase of 65 over the preceding year. At the close of the fiscal year there remained under treatment 49 patients. Of the number under treatment in the hospital 668 were discharged cured, 109 improved, 12 unimproved, 58 were given advice but not treated, and 47 patients died.

MARYLAND.

Graduates Gather Medical Articles.—The graduates of the Johns Hopkins Medical School have sent their "Collected Papers" to Dr. William Osler. They are contained in 12 superbly bound quarto volumes with index and also a table of contents for each. They represent eight years of work and embrace 465 separate contributions relating to a great variety of subjects.

New Hospital Opens.—The new Allegany County Hospital, Cumberland, held its formal opening December 8. The following comprise the directors of the medical staff: Dr. E. B. Claybrooke, president; Dr. C. H. Brace, vice-president; Mr. Arch A. Young, secretary and treasurer; Drs. George L. Broadrup and Arthur H. Hawkins, and Messrs Lloyd Lowens and R. A. Claybrooke. The attending staff is composed as follows: Surgical, Drs. W. R. Foard, E. B. Claybrooke, Henry S. Wailes, Arthur R. Hawkins, George L. Carder and Edwin Harris; medical, Drs. C. H. Brace, George L. Broadrup, C. L. Owens, Willys R. Hodges and E. H. White; eye, ear, nose and throat, Drs. Robert Y. Fechtig and E. L. Jones, and pathologist, Dr. W. R. Foard.

Baltimore.

Opie's Portrait.—A movement is on foot at the College of Physicians and Surgeons to have a portrait of Dr. Thomas

Opie, the late dean, painted, to be hung in the college building. Dr. Opie has given the college library a large number of books.

Personal.—Dr. Howard Kelly, accompanied by four of his children, will leave for a hunting and fishing trip in Florida the last of this month.

Hospital Incorporated.—St. Luke's Hospital was incorporated December 13 by a number of physicians, to conduct a hospital. dispensary and training school for nurses.

Internes Resign.—The four internes at the City Hospital whose resignation was recently noted severed their connection with the hospital, it is reported, because one of their classmates had been placed in authority over them. The vacancies have been filled.

Pasteur Institute Report.—In his annual report of the Pasteur department of the City Hospital, Dr. Nathaniel G. Keirle, director, claims that there has been but one death out of the 775 cases. Three other patients died, but before they had received the full treatment.

Visiting Nurses' Work.—The Instructive Visiting Nurses' Association held its annual meeting December 5. It was addressed by Dr. Lewellys F. Barker and Miss Damer, president of the Association of Nurses of the United States. The report showed that eight nurses had made 23,811 visits, and that a deficit existed of $541. Dr. Barker urged that there was eight times as much work to be done, and that the hospitals can not begin to care for all who need medical attention.

Personal.—Dr. James D. Iglehart is in New York City.——Dr. Santiago U. Samodeville will spend the winter in Havana.——Dr. William H. Welch has been elected a member of the board of trustees of the Carnegie Institute, in place of the late John Hay.——Dr. George A. Hartman has been appointed a member of the jail board.——Drs. Alexander D. McConachie, Arthur Wegefarth and Edward A. Hartman were elected directors of the Northeastern Dispensary.——Dr. B. Merrill Hopkinson has been elected president of the Baltimore Athletic Club for the fourteenth consecutive year.

MASSACHUSETTS.

Rival Candidates Physicians.—The city of Worcester elected for mayor, December 12, Dr. John T. Duggan, a democrat. His competitor was Dr. Melvin G. Overlook, republican.

Insane Hospital Report.—The trustees of the Northampton Hospital report that on October 1 there were 771 patients; 401 were admitted during the year, 303 were discharged and 79 died. Of the admissions, 199 were men and 202 women. Of those discharged, 84 were well, 30 improved and 25 not improved. The weekly cost per capita was $3.57, 21 cents less than last year. Under the new law of the state, 9 patients were boarded out. The average duration of insanity in those who died was 19 years, and the average length of stay in the hospital 9 years.

Hospital News.—At the annual meeting of the North Adams Hospital staff October 31, Dr. Henry J. Millard was elected president, and Dr. Edward E. Russell, secretary; Drs. Frank D. Stafford and Adolphe Mignault were elected members of the advisory board, and Dr. John F. C. Forrester was made a member of the staff.——By the generosity of D. B. Wesson, a maternity hospital will be added to the charitable institutions of Springfield. It will contain 25 rooms and will cost from $100,000 to $200,000.——A. C. Houghton, North Adams, has given a new operating room to the North Adams Hospital.——Mr. and Mrs. F. A. Day, Newton, have presented a new building to Newton Hospital, to be used as a home for nurses, which has cost about $30,000.

MINNESOTA.

Hospital Incorporated.—The United Church Hospital, Minneapolis, was incorporated December 9.

Sanitarium Burned.—Pine Ridge Sanitarium for Consumptives was destroyed by fire December 2, entailing a loss of about $2,000.

Dr. Bly Guilty.—Dr. Theron H. Bly, Minneapolis, was found guilty, on December 8, of performing a criminal operation on Hilda Rosen which resulted in her death. The prisoner was released after filing a $2,000 appeal bond.

Dr. Smeallie's Death.—The widow of Dr. James A. Smeallie, Cass Lake, whose death notice appeared in The Journal of December 9, writes that he died after an illness of nine days from pleuro-pneumonia, and not from tuberculosis, as stated.

Rules Against Physicians' Defense Company.—The attorney-general of Minnesota has ruled against the Physicians' Defense Company in its complaint against the Maryland Casualty Company and other casualty companies which are writing physicians' defense policies in Minnesota. The ruling asserts that not only may the casualty company continue to write physicians' defense contracts, but that hereafter the Physicians' Defense Company must comply with the Minnesota insurance laws, which has not heretofore been required.

MONTANA.

Personal.—Dr. M. William Feenan, Anaconda, has been appointed county physician of Butte County, vice Dr. T. J. McKenzie, term expired.

Medical Examiners Sustained.—After short deliberation December 7, the first jury in the history of the state, composed solely of physicians, returned a verdict sustaining the action of the State Board of Medical Examiners in refusing a certificate to practice medicine to John H. Foley, Great Falls. This jury was subpenaed under the law passed by the last legislature, which provides that a jury of doctors may be subpenaed by a district judge to hear an appeal in such cases.

NEBRASKA.

Faculty Changes.—The following changes have been made in the faculty of the College of Medicine of the University of Nebraska, Lincoln: Dr. Charles W. M. Poynter, adjunct professor of anatomy; Dr. L. B. Pilsbury, instructor in bacteriology and pathology; Dr. John M. Mayhew, instructor in medicine; Dr. Harry H. Everett, instructor in surgical pathology, and Dr. Harry J. Lehnhoff, instructor in surgery.

Hospital Dedicated.—The new Swedish Hospital, Omaha, was dedicated November 19, the dedication address being delivered by the Hon. John L. Kennedy. The hospital will accommodate 28 patients. The medical staff is made up as follows: Dr. Arthur C. Stokes, attending surgeon; Dr. Roy A. Dodge, assistant; Dr. Charles C. Allison, consulting surgeon; Drs. William R. Hobbs, Rudolph Rix, Carl L. F. Swanson and Paul H. Ellis, attending physicians; Dr. Samuel K. Spalding, mental and nervous diseases; Dr. H. L. Akin, diseases of the stomach; Dr. Harry M. McClanahan, diseases of children; Dr. D. C. Bryant, diseases of the eye and ear; Dr. George H. Bicknell, diseases of the nose and throat, and Dr. James S. Foote, pathologist.

NEW JERSEY.

Hospital Incorporated.—The Hospital of the Immaculate Conception has been incorporated at Orange.

Found Guilty.—Dr. Alfred C. Pedrick, Passaic, on December 5 was found guilty of performing a criminal operation on Mrs. Mary Steinberg, Passaic, by reason of which she was placed in imminent danger of death. Sentence was deferred.

Contagious Diseases.—There have been reported 18 cases of scarlet fever in Paulsboro and two of the schools have been closed. Two cases of diphtheria have also developed.——Dunellen is under quarantine on account of the prevalence of diphtheria.

Personal.—Dr. William H. Shipps, Bordentown, has been elected acting secretary of the State Board of Medical Examiners, vice Dr. E. L. B. Godfrey, Camden, away on leave of absence.——Dr. Henry B. Whitehorn, Verona, has been chosen president and Dr. Edwin M. Ward, Bloomfield, vice-president, of the Mountain Side Hospital staff, Montclair. Dr. Charles H. Bailey, Bloomfield, has resigned as president of the hospital.——Dr. H. H. Tomlin, Hammonton, has been appointed junior resident physician at the Altoona (Pa.) Hospital.

NEW YORK.

Physicians' Club.—The physicians of Poughkeepsie have formed a club for scientific and social discussion, to meet monthly at the houses of its members.

Resolution Against Tuberculosis Hospital.—The Medical Society of Richmond County has adopted a resolution condemning the proposition to build a $2,000,000 tuberculosis hospital in Richmond, declaring that the climate there was detrimental to the successful treatment of this disease. It is claimed that such an institution would be detrimental to the health and best interests of Staten Island.

New York City.

Medical Officer for the Comptroller.—The post of medical examiner for the finance department, with a salary of $2,500, was created on the recommendation of Comptroller Grout. The duty of this officer will be to look after the claims against the city for damages for personal injuries.

Aid for Hebrew Sanatorium.—The following additional subscriptions have been received for the Sanatorium for Hebrew

Children at Rockaway Park: Charles L. Hallgarten, $500; Sigmund Newstadt, $500; Mrs. A. Scheitel, $150. The subscriptions for this institution now amount to about $25,000.

Bellevue Rebels.—Bellevue has rebelled against drunkards. Dr. A. Armstrong has issued an order that plain alcoholic patients will not be extended the courtesy of the hospital during the sobering-up process. It is feared that this order may cause a rupture between the hospital authorities and the police, for the latter have repeatedly mistaken cases of fractured skull for alcoholism.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended December 9, 429 cases of tuberculosis, with 177 deaths; 572 cases of measles, with 7 deaths; 334 cases of diphtheria, with 40 deaths; 187 cases of scarlet fever, with 6 deaths; 94 cases of typhoid fever, with 13 deaths; 34 cases of cerebrospinal meningitis, with 15 deaths, and 222 cases of varicella. This is a total of 1,872 cases, with 258 deaths.

For Psychical Research.—Prof. James H. Hyslop has issued a prospectus of the American Institute of Scientific Research that has just been incorporated and which intends to study abnormal psychology. It is intended that the institute shall be something like the Salpêtrière under Charcot and Pierre Janet. It is proposed to study loss of the sense of personal identity, persistent hallucination, amnesia, psychic epilepsy, melancholia and paranoia.

Institute Soon to be Opened.—The Rockefeller Institute for Medical Research, to which John D. Rockefeller has given $3.000,000, will be ready for occupancy the first week in January. The site includes 26 city lots. Appointments to the staff of the laboratory will be announced soon by the board of directors. The institute will continue to aid investigators in this country and in Europe. There are now 20 men working under the auspices of the institute outside of New York. Grants of money are made to students in medical research.

Tuberculosis in New York City.—The third annual report of the committee on the prevention of tuberculosis of the Charity Organization Society says: "The tuberculosis situation in New York City is unique. At once we have, though not the highest death rate, a larger number of deaths and a far greater number of cases of sickness than any other city in the country; at the same time tnat we have a system of public and private control of the disease that with more candor than modesty we may claim as the superior of any elsewhere existing in the United States." The charity department maintained 3,959 patients in its own hospitals last year, and paid for the treatment of 783 patients in private institutions each month. The other agencies for fighting tuberculosis were eight special dispensaries, the special arrangements at Bellevue Hospital, the seaside work for improving the condition of the poor, and several others.

OHIO.

St. Alexis Alumni Meet.—The regular meeting of the alumni association of resident physicians of St. Alexis' Hospital, Cleveland, was held December 7 at the Hollenden Hotel.

Epidemics.—On account of an epidemic of scarlet fever at Jefferson the primary grades of the public schools have been ordered closed, and all Sunday schools in the town have been ordered to discontinue their sessions.——The public schools of New Philadelphia have been closed by the board of health on account of an epidemic of diphtheria; the rehearsals for an amateur theatrical performance were ordered discontinued; Sunday schools were not open for children, and children were prohibited from gathering in groups in the streets and in their homes.

State Hospital Report.—The forty-sixth annual report of the directors of Longview Hospital shows that the average of patients was 1,100, and the total number of deaths for the year, 61. The current expenditures were $184,194.20. During the year the county expended for permanent improvements $54,335.89.——The thirteenth annual report of the trustees of the Massillon State Hospital shows that the last of the new buildings authorized in 1904 is practically completed, and that there remains to be erected only one building, which is to be fireproof and designed as a hospital. During the year 404 patients were admitted and 390 were discharged, of whom 136 were considered cured, 57 improved, 13 unimproved, and 184 dead. The percentage of recoveries was 33.66. The superintendent reiterates in his report his frequently expressed opinion that inebriety is surely the forerunner of insanity. The per capita cost per annum was $108.70, or, including officers' salaries, $114.84.——The charges made by Dr. James F. Kelly, assistant superintendent, and by a clergyman of Cleveland, against the superintendent and steward of the Cleveland State Hospital, were investigated by the board of trustees and not sustained. Dr. Kelly resigned.——The commission appointed to select a site for the proposed new State Hospital for the Criminal Insane has selected a site offered by the city of Lima.

PENNSYLVANIA.

Portrait Presented.—At the regular meeting of the Erie County Medical Society, November 15, it was announced that a large portrait and all the books of the late Dr. Charles Brandes had been presented to the society by the heirs.

Personal.—Dr. William N. Stein, Shenandoah, a member of the local board of health, was appointed state medical inspector for the Shenandoah district.——Dr. Solon C. B. Fogel, Allentown, while alighting from a trolley car, December 13, fell and fractured his left leg.

Pure Food Report.—The report of the state dairy and food commissioner, published November 24, states that the results obtained by the department indicate the need for legislation regulating the manufacture and sale of drugs and chemicals. The department found that from 50 to 75 per cent. of spices are adulterated and that adulterants are used freely in confections, soda-water, jellies, jams and preserves. The investigations disclosed furthermore that certain "pure rye whiskey" is nothing more than a mixture of alcohol, prune juice and caramel. Certain brands of so-called fruit syrups, the report states, do not contain a particle of the fruit for which they are named.

Philadelphia.

Personal.—Dr. John M. Fisher has been appointed visiting chief gynecologist to St. Agnes' Hospital.

Bequests.—By the will of the late Margaretha K. Engel, the German Hospital receives $1,000.——The will of the late Solomon J. May contains a bequest of $150 for the Jewish Hospital.

Chickenpox on Steamship.—Twelve cases of chickenpox were discovered on the arrival of the steamship *Merion* at this port, November 22. The patients were removed to the Municipal Hospital.

Reading's Relief Report.—The statement of the Philadelphia & Reading Relief Association for November showed an expenditure of $23,714.80, of which $12,350 was paid for deaths and $11,364.80 for disability. The number of deaths was 22, of which 8 were from accidental and 14 from natural causes. Twelve hundred and thirty-five new cases were reported.

Bacteriologic Report.—The report of the bacteriologic laboratory of the Health Bureau for November shows that 1,295 diphtheria cultures were examined, 400 Widal reactions were made, 906 specimens of milk and 113 specimens of sputum were examined, and 3 disinfection tests were performed. The report also shows that 3,134,000 units of antitoxin were distributed.

Health Report.—The total number of deaths from all causes reported for the week reached 509, as compared with 479 reported last week, and 519 reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 10; measles, 5; diphtheria, 13; tuberculosis, 51; cancer, 17; apoplexy, 32; heart disease, 58; acute respiratory disease, 94; enteritis, 17; Bright's disease, 47; old age, 8; suicide, 7; accidents, 21, and marasmus, 8. There were 240 cases of contagious disease reported, with 26 deaths, as compared with 291 cases and 29 deaths for the previous week. Typhoid fever shows a falling off, as 111 cases only were reported this week as compared with 152 for last week.

Indiscriminate Sale of Drugs.—It has been discovered that narcotics, particularly cocain and morphin, are being sold by certain druggists in the rougher section of the city. Several young men have been discovered wholly under the influence of narcotics. Arrests have been made and it has been learned by the authorities that the cocain habitués have obtained the drug by a secret cipher code. The key to the code was given by one of the victims to the captain of detectives. The key was then tried by the captain and the drug secured. The Philadelphia Association of Retail Druggists, at a meeting December 8, adopted resolutions denouncing all pharmacists who abuse the cocain laws. Each of the druggists thus far arrested has been held in $1,000 bail.

Medical Inspection in November.—The report of the division of medical inspection for November shows that 4,705 inspections were made, excluding schools; 842 fumigations were ordered; 26 patients were examined for special diagnosis; 426 cultures were collected; 495 vaccinations were performed, and 226 injections of antitoxin were given. The report further shows that 6,030 visits to the schools were made and that 994 children were excluded from attendance on account of disease. In all 30,524 pupils were examined and 5,310 found to be in need of medical attention. The principal diseases for which children were excluded were: Diphtheria, 14; scarlet fever, 15; measles, 15; variola, 34; ringworm, 34; tonsillitis, 58; mumps, 13; unvaccinated, 228; sprain, 1; abscess, 1. Of the 5,310 pupils recommended for treatment there were: Defective vision, 1,995; defective hearing, 166; defective speech, 19; defective teeth, 493; nasal catarrh, 113; tonsillitis, 8; eczema, 204; cataract, 1; infected wounds, 22; abscess, 19; sprains, 5; fractures, 3; carbuncle, 1; bronchitis, 18; jaundice, 1; rheumatism, 2, and revaccination, 32.

VERMONT.

Diphtheria.—Diphtheria is reported to be prevalent among the children of Burlington, and the health officer, Dr. James W. Courtney, has been instructed by the State Board of Health to make a physical examination of all children of the public schools.——Because of the appearance of diphtheria, the high and graded schools at Winooski have been ordered closed.

Benefit for Hospitals.—Nahum P. Kingsley, Rutland, has given the Rutland Hospital Association his personal check for $1,000, to be held as a trust fund, and the interest used in the maintenance of the institution.——The court has directed the executor of Col. William Austin to pay the bequest left by him for a hospital in Brattleboro to the authorities of the town, to be paid over to the hospital trustees when required.

VIRGINIA.

New Hospital.—John B. Newton, vice-president of the Virginia Iron, Coal and Coke Company, Bristol, has donated a suitable piece of land for the erection of a hospital to cost $50,000.

Hospital Secured.—The directors of the Norfolk Protestant Hospital secured, by public subscription, $11,000 of the $24,000 necessary to obtain the donation of $18,000 offered by Messrs. George L. Arps, J. W. Perry and Fergus Reed, to place the hospital out of debt, decided to underwrite the $13,000 remaining, and called on the provisional donors for the payment of the amount pledged.

WISCONSIN.

Do Not Want Names Published.—At a meeting of the Fond du Lac County Medical Society, November 9, a resolution was adopted in which the society requests that the newspapers of the city refrain from publishing the names of physicians connected with operations or accidents.

Doctors Must Take Oath.—Judge Brazee, Milwaukee, has issued an order regarding practice in the Municipal Court, to be known as rule No. 16, which sets forth that "certificates of physicians presented to the court must be subscribed to by the physician and must be sworn to by him before some official authorized to administer an oath."

Injunction Dissolved.—Dr. J. A. Schmidt, Brillion, was granted an injunction a few weeks ago against Dr. Edward Meyer, who was forbidden to practice medicine in Brillion. The restraining order was modified to permit Dr. Meyer to treat the patients he had at the time the injunction was granted. Dr. Schmidt claimed that he had a contract in which Dr. Meyer transferred certain personal property to Dr. Schmidt, including his "field of practice in this community." Judge Burnell, at Oshkosh, has decided to dissolve the injunction and Dr. Meyer is allowed to practice, but is required to make an accounting on the business done by him to the court.

GENERAL.

Yellow Fever in Cuba.—Cases of yellow fever are still reported from in and around Havana. Cases are being reported as occurring outside of what has been known as the infected district. Dr. von Ezdorf, of the Public Health and Marine-Hospital Service, reports that rain has prevailed the latter part of the week, which is unusual for this time of year. In looking over the record of yellow-fever cases reported, he states that it is interesting to note the large proportion of individuals who have contracted the disease after a short residence on the island. On December 13, two additional cases of yellow fever were reported at Colon, in the province of Matanzas.

Hawaiian Medical Association.—The annual meeting of this association was held November 18. Health affairs were discussed at some length. Dr. Day pointed out that typhoid causes a high death rate in Honolulu and urged that a better water supply should be provided. Dr. Goodhue urged the establishment of a school of tropical medicine in Honolulu, and a committee was appointed to consider the matter and report. Dr. Hodgins spoke on infant feeding and started an interesting discussion on the respective merits of condensed and sterilized milk. Dr. Peterson, superintendent of the insane asylum, declared that insane patients or those suspected of being insane are not treated as sick persons, but are arrested and thrown into jail and receive treatment that is not at all a credit to the community. The statements were corroborated by other members of the association, and a committee was appointed to consult with the bar association concerning appropriate legislation that might be submitted to the next legislature. A number of members visited the Russian cruiser *Lena*, where, as the guests of Dr. Vladimir Zabotkin, they received most courteous treatment.

Yellow Fever News.—Havana, on December 8, reported up to that date 48 cases of yellow fever, with 14 deaths. On December 11 it was reported that 15 cases were under treatment. There are now 445 men employed in the yellow-fever brigade, of whom 325 are engaged in fumigating, 100 are applying petroleum to all stagnant water, and 20 are inspecting tanks, barrels, etc. Two physicians have been fined $50 each for failing to report cases.——Arkansas finds that its military quarantine cost $36,000, all spent in maintaining a quarantine of the good old-fashioned shotgun type.——Augusta, Ga., spent $2,764.45 on its yellow-fever quarantine.——The state of Tennessee spent $10,300 in quarantine.——The work of the American Mosquito Extermination Society, New York, is commencing to be felt.——Oklahoma school authorities have about decided to include the mosquito doctrine among t[illegible] jects of study.——Surgeon J. H. White, [illegible] Health and Marine-Hospital Service, has been detailed to the New Orleans station. He will have as his assistants Passed Assistant Surgeons Corput, Wilson, and McKeon, all of whom saw service during the recent epidemic.——The New Orleans Health Association, on December 10, by a vote of 25 to 7, passed a resolution demanding the resignation of Health Officer Kohnke on the ground of loss of public confidence. They also appointed a committee to visit Governor Blanchard and to ask him to permit the State Medical Society to name the president of the State Board of Health.

First Meeting Under Amalgamation.—The new house of delegates of the Medical Society of the State of New York met in Albany December 14, including the chairmen of the standing committees and the joint committee of ten. The secretary was ordered to notify all county societies of the fact that they should reorganize so as to agree with the constitution and by-laws, which was part of the agreement of amalgamation. All association members were also to be notified. The counsel who made application for consolidation gave the opinion that the order from the Supreme Court judge made all members of the New York State Medical Association who are in good standing members of the Medical Society of the State of New York on the receipt of a certificate of the president and secretary of the state association. It was decided to continue the journal and the medical directory and to continue the malpractice defense for the members of the Medical Society of the State of New York. The president and secretary were ordered to continue the journal for January and February, and a committee to be appointed by the president is to select an editor and to report at the annual meeting of the House of Delegates next month. A committee of five was appointed, of which the president is one, to carry out the referendum as per Section 7 of the court order relating to the Principles of Ethics of the American Medical Association. The constitution of the American Medical Association provides that when any state medical society is reorganized according to the plan of the American Medical Association, and by resolution expresses its allegiance to that body, it then becomes a constituent branch of it. Such a resolution was [illegible] l. The per capita assessment on members [illegible] placed at $3.00. A tentative constitution and by-laws for county societies was submitted as being suggestive and which might be adopted with very slight alteration by the several county medical societies of the state.

FOREIGN.

Endowment for Scientific Research at Berlin.—A Berlin lawyer has given $12,500 to start a fund to supply financial aid to scientists studying important problems in the natural sciences, including biology and medicine.

Congress of Balneology.—The German and Austrian balneologic societies will unite in a congress to be held at Dresden in March. Liebreich will preside. The general secretary of the German association and of the congress is Dr. Ruge, Berlin W., Magdeburgerstrasse 31.

Plague in Japan and China.—Assistant Surgeon Ransom reports that plague has been declared epidemic in Osaka and Kobe. In Osaka, from November 2 to 17, there were 23 cases, with 15 deaths. Shanghai and Chefoo have declared quarantine against Nieuchwang on account of plague.

Organization of Anglo-Mexican Association.—The first meeting of this body is to be held at Torreon, Mexico, in January. At first it was proposed to limit the membership to physicians in northern Mexico, but later it was decided that all English-speaking physicians in the republic should be eligible for membership.

Skoda's Centennial.—The profession of Vienna united in a memorial meeting on December 11, the hundredth anniversary of the birth of Josef Skoda. He was professor at Vienna for only twenty-five years, but during this period won international fame by his study of physical methods of examination. He resigned his chair in 1871 on account of illness, and died ten years afterward.

Czerny to Devote Himself to Cancer Research.—It is reported that Prof. V. Czerny is to retire from the surgical clinic at Heidelberg in order to devote his energies exclusively to the Institute for Cancer Research, which was recently founded there mainly by his efforts and donations. Garrè, who recently took Mikulicz's vacant chair at Breslau, is suggested as Czerny's successor. Nearly $200,000 have been subscribed for the new cancer institute.

Beriberi Arrives at Glasgow.—The danger of the introduction of tropical diseases to other countries through the media of vessels and their crews seems to be a very real one. On December 2 two Chinamen, both firemen on board the steamer *Peleus*, which arrived in the Clyde from the Far East, via Marseilles, were discovered to be suffering from beriberi, and were removed to Belvidere Fever Hospital, Glasgow. All precautions are being taken by the sanitary authorities.

Catalogue of Ancient Medical Works.—The *Deutsche med. Wochft.* announces that the Copenhagen and the Berlin academies of science have united in publishing a catalog of all the Greek and Latin medical writings that have been handed down to us from antiquity. This catalog is to be preliminary to the suggestion that the International Association of Academies of Science undertake the task of publishing a complete scientific edition of the collected works of the physicians of antiquity. The plan is to be proposed at the next general meeting of the delegates of the association, which will be held at Vienna during the spring of 1907.

International Congress of Gynecology, St. Petersburg, September, 1906.—The committee of organization of this congress, which was postponed from last to next September, is said to be actively at work preparing for the meeting. The committee includes twenty of the most prominent gynecologists of Russia, with D. von Ott as chairman. Prof. P. Sadowski, Newski Prospekt 90, is secretary general of the congress, while Dr. Redlich has charge of the exhibition annex. His address is Spasskaja 25, both in St. Petersburg. The *St. Petersb. med. Wochft.* states that the committee requests prompt notification in regard to communications to be presented, so that summaries can be published and distributed in time. Our exchange adds, further, that trips to the Caucasus, Crimea and down the Volga will be offered the members of the congress at reduced rates. The same journal states elsewhere that Professor von Ott has been removed from the superintendency of the Gynecologic Institute at St. Petersburg, his place having been taken by Dr. Salaskin. No reasons are assigned for his removal from the famous model institution erected under his supervision.

The Austrian Society to Combat Quackery.—The program adopted by the Austrian society, whose foundation was mentioned in these columns last week, includes efforts to enlighten the people and banish superstition by popular lectures on anatomy, physiology and pathology; by replies on the spot by bright and able medical speakers when statements are made abusing science during the meetings of antivivisectionists, nature healers or other faddists; by analyses of secret remedies and publication of the results, as is being done by the Germans at some places, and by rigid enforcement of all measures tending to restrict the practice of irregulars. The president, Professor Kassowitz, emphasized the fact that quackery is constantly sapping the foundations of science and discrediting its results. The necessity for enlightening the people in this respect is well brought out by a Vienna correspondent in the *Muench. med. Wochft.* for December 5. He states that a bill appropriating less than $8,000 for public vaccination purposes in a certain district was passed by the legislature for lower Austria by a majority of only one vote. The deputies were almost evenly divided on the question of the necessity of vaccination. One asserted that if physicians were not paid for vaccinating people there would soon be plenty of testimony to the effect that vaccination does no good.

The Nobel Prizes.—Only one physician is honored with one of the Nobel prizes this year, Robert Koch. The other recipients are A. von Baeyer, Munich, an authority on organic chemistry, and P. Lesnard, of Kiel, for researches on the cathode rays. The author of "Quo Vadis," M. Sienkiewicz, receives the prize given for idealistic literature, on account of his trilogy of Polish historical novels, while the Baroness von Suttner is given the peace prize for her works and writings to promote the cause of peace. The career of Robert Koch is known to all our readers, as his name is so closely connected with modern bacteriology and serotherapy. He is not content to rest on his laurels, but is constantly seeking new worlds to conquer, having just completed a year of research in Africa. The important results of his labors were mentioned on page 1888 of our last issue. He was born in Clausthal Dec. 11, 1843. His epoch-making bacteriologic discoveries first attracted attention to him in 1876 while he was serving as district physician in Prussian Poland. Aft [illegible] at Göttingen he served as assistant in the [illegible] and then opened an office at Langenhagen and later at Rackwitz until, in 1872, he was appointed district physician at Wollstein, near by. Here he remained until 1880, when he was summoned to Berlin as a member of the Imperial Council of Health. His discovery of the tubercle bacillus followed two years later and of the cholera bacillus the following year. He was appointed director of the newly founded Institute for Infectious Diseases at Berlin in 1891, and his announcements in regard to tuberculin laid the foundation of serotherapy not long after. His trip to Africa in 1896 added to our knowledge in regard to malaria, the immunity of adults and means of prophylaxis. The Nobel prizes were founded by the inventor of dynamite, Alfred Nobel. They amount this year to about $40,000 each. The trustees in charge of the awarding of the prizes do not seem to be aware that there is such a continent as America on the globe, but the lengthening list of the recipients of the prizes is gradually becoming a hall of fame for the great men of Europe. Germany, France, England, Spain, Switzerland, Russia, Sweden and Denmark have each been honored with one or more prizes. The physicians who have received the medicine prize to date are von Behring of Germany, Major Ross of England, Finsen of Denmark, Pawlow of Russia and Robert Koch.

LONDON LETTER.

The London Milk Supply.

Dr. Collingridge, health officer of the city of London, has made a very unfavorable report on the milk supply of the metropolis. Last year bacteriologic examination of samples of milk from 22 counties showed that only 19 out of 39 were clean and pure. Since then the investigation has been continued and samples of milk from 22 counties have been submitted to Dr. Klein for examination. He found that 15 out of 22 samples were clean and pure; 5 were unclean, and 2 contained the *Bacillus tuberculosis*. These results point to the grossest carelessness, amounting, in fact, to criminal negligence. Several guinea-pigs which were injected with the milk died from extensive pneumonia or typical septicemia, with copious presence of *Bacillus coli communis* in the blood, and in all the viscera, or acute peritonitis. One-third of the samples examined were thus unfit for use.

Bovine Typhus in Egypt.

Egypt has been officially declared free of bovine typhus and the provincial cattle markets, which have been closed for two years or more, will be reopened, provided that no fresh outbreak occurs. This disease has swept away $5,000,000 worth of cattle, and Koch, on his return from his rinderpest campaign in South Africa, was called on to advise the Egyptian government as to the means of exterminating it. He prescribed the complete isolation of diseased animals and serum inoculation. Some time after his visit to Egypt the disease seemed to increase in virulence and skeptics shook their heads with regard to his advice, but the sanitary department was in capable hands and an extensive inspectorate was established throughout Egypt and in the long run Koch's measures have prevailed. The serum institute at Abasieh is being closed, but a large quantity of rinderpest serum is being kept in cold storage for emergencies. Intelligence has just been received at Cairo that cattle plague has broken out anew in the Sudan. Serum is being dispatched from Cairo with several veterinary inspectors who can now be spared from duty in Egypt.

Distribution and Spread of Sleeping Sickness in the Congo Free State.

At the Epidemiological Society, London, Dr. J. L. Todd read an important paper on this subject, based on observations and inquiries made during a journey of 2,000 miles and a residence of two years in the Congo by himself and the late Dr. Dutton, who had been sent out by the Liverpool School of Tropical Medicine. Dr. Todd exhibited three spot maps showing the prevalence and distribution of the disease—one for 1884, when European influence was only coming into existence and sleeping sickness followed the native and Arab trade routes; a second for 1897, when the Arabs were expelled, and with the extension of long-distance transport by caravans and steamboats the disease spread in every direction, and a third for 1905, when European supremacy being fully established, and transport being easy and rapid, there was an enormous extension of the trypanosomiasis mainly from aggregation at posts along the lines of trade of native soldiers and laborers, often recruited from infected districts. The intermediate host of the *Trypanosoma gambiense* (the parasite of sleeping sickness), the *Glossina palpalis*, though not aquatic in its larval stage, prefers moist places. The areas of greatest prevalence are the river sides and shores of lakes. Frequently riverine populations show an incidence of trypanosomiasis of from 15 or 20 per cent. while the natives on higher ground escape. The chronicity of the disease is such that the parasites may be present for as long as fifteen years without producing symptoms. On the other hand, death may occur a few months after infection. The alarming spread of the sickness demands vigorous measures. In default of curative treatment Dr. Todd thinks that the only practical procedures are: 1, Establishment on the main roads leading to healthy districts of posts of inspection; 2, expulsion from healthy districts of persons having enlarged glands and their removal to infected districts; 3, control over the migration of the natives. In the diagnosis gland palpation is sufficient for practical purposes, though puncture would be required for scientific.

The Tuberculous Children of London.

At a meeting of the Invalid Children's Aid Association to discuss the action to be taken with regard to children affected or suspected to be affected with pulmonary tuberculosis, Sir William Broadbent, in an address entitled "The Tuberculous Children of the Metropolis," said that it was remarkable that while consumption, the most prevalent form of tubercular disease, has steadily diminished year by year for the last 30 years, there has been no corresponding diminution in the death rate of the tuberculous affections which are specially incident in childhood—meningitis, peritonitis, tabes mesenterica, disease of bones and joints, and scrofulous glands. On the contrary, these have increased. During the years 1901-03 in London 6,391 children under 5 died from different forms of tuberculosis; of these 2,894 died before the age of one year, the mortality decreasing rapidly with every successive year of life. The association can do little or nothing for cases of true pulmonary consumption which come under its cognizance beyond sending the children in early stages into the country. Such cases constitute a small minority of the affections of the lungs met among London children. It is astonishing what an amount of damage to the lungs is survived with apparent restoration of health and vigor. Sequels of measles, whooping cough, bronchitis and other affections are often mistaken for consumption and there are no cases in which fresh air and good food make a greater difference. A child otherwise condemned to lifelong delicacy and suffering, by a change to the country or to the seaside, may be made permanently well. The association should be encouraged to take charge of children suffering from disease of the lungs of whatever kind. In France far more attention has been paid to this question. In England an excellent beginning had been made in the Millfield Home, on the south coast near Littlehampton, for children suffering from pulmonary tuberculosis, under the control of the metropolitan asylums board. For children above the pauper class there is very little accommodation. Sir William Broadbent condemned the so-called comforter or teat, constantly seen in the mouths of infants of all classes, as an invention of the devil. It is, he said, a fraud on the unhappy child; it leads to waste of the digestive secretions, and it picks up every kind of filth when it falls on the floor. On reviewing the whole question, he said that what impresses him is the extent of the demand for institutional accommodation and the inadequacy of the provision. A resolution was carried approving of the practice of the association in endeavoring to make possible early and efficient treatment of children suffering from surgical tuberculosis by assisting to pay for them in nursing homes and special hospitals.

Pharmacology

The Press Committee of the Proprietary Association.

As a matter for publicity, we give below a list of the members of the Press Committee of the Proprietary Association. This committee is doing some very effective work in supplying to the newspapers of the country, which are willing to be dictated to, material to counteract the exposing of frauds in "patent medicines." It will be noticed that this committee represents some of the worst among the "patent medicines." What will be of special interest to physicians, however, is the fact that there are men on the committee who represent preparations that are being advertised to the medical profession through medical journals. For instance, Scott & Bowne, who, besides their "patent medicines," exploit to the public and to the medical profession "Scott's Emulsion." Wells, Richardson & Co., of "Paine's Celery Compound" fame, appeal to the medical profession to help them sell their "Cereal Milk." W. A. Talbot represents on the committee "Piso's Cure for Consumption," but who, at the same time, is with the Micajah Co., and is appealing to physicians to use "Micajah's Medicated Uterine Wafers." This is another bit of evidence to convince those not already convinced that we can not separate the so-called "patent medicines" from the "ethical proprietaries." The following is the list:

A. H. Beardsley, chairman (Dr. Miles' Nervine, etc.).
F. W. Schumacher (Peruna).
S. W. Bowne (Scott's Emulsion, Buckthorn Cordial).
H. E. Bucklin (King's New Discovery, Electric Bitters, etc.).
D. S. Chamberlain (Cough Remedy, Pain Balm, etc.)
R. R. Land (Swamp-Root Kidney, Liver and Bladder Cure, etc.).
E. C. DeWitt (Little Early Risers, Dyspepsia Cure etc.).
J. F. Hindes (Bromo-Seltzer, Rheumatic Cure, etc.).
H. B. Foley (Foley's Kidney Cure, etc.).
O. E. Foster (Doan's Kidney Pills, Burdock Blood Bitters, etc.).
W. T. Hanson (Pink Pills for Pale People, etc.).
H. L. Kramer (Cascarets, Kidney Pills, etc.).
G. A. Newmann (California Fig Syrup).
J. A. Patten (Wine of Cardui, etc.).
C. A. Rucker (Swift's Specific).
C. I. Shoop (Shoop's Restorative).
C. G. Hopkins (Liquozone).
F. A. Stuart (Dyspepsia Tablets, Absorbent Lozenges).
W. A. Talbott (Piso Cure for Consumption, etc.; also Micajah's Medicated Uterine Wafers).
G. B. Rowell (Ripan's Tabules).
J. T. Wetherald (Lydia E. Pinkham's Vegetable Compound, etc.).
G. B. Van Cleave (Paine's Celery Compound, etc.).
I. M. Clark (Laxative Bromo-Quinin Tablets, etc.).

Not Members of Proprietary Association.

Among the list of members of the Proprietary Association of America, which we published Nov. 18, was mentioned the firm of Fairchild Brothers & Foster. They write that some years ago they consented to join the association because of their interest in the matter of trademarks, but that they never took any active interest in the association or attended its meetings. They say: "Believing that our judgment was at fault in this matter, we have resigned our membership."

Opportunities for Missionary Work in China.

We wish to direct the attention of nostrum manufacturers to a recommendation made by Consul George E. Anderson of Amoy, China. Writing concerning business and professional opportunities in China, he says: "The Chinese are favorable to the patent medicine business if it can be brought within their reach. They naturally take to such a method of treating diseases, and remedies advertised as they are in the United States and Europe would have a big sale in China, provided the prices charged for them would be within the reach of the middle class." Some patent medicine men, in connection with their threats to sue certain publications which have exposed the fraudulent nature of their business, stated that these exposures have occasioned much loss of patronage; they, therefore, may need a new field in which to push the sale of their products. To judge from this report of Consul Ander-

COMPARATIVE TABLE SHOWING THE STRENGTH OF THE MORE IMPORTANT PHARMACOPEIAL SUBSTANCES AND *PREPARATIONS* IN THE PRECEDING AND IN THE PRESENT PHARMACOPEIA.

Title.	Chief constituent.	Pharmacopeia, 1890	Pharmacopeia, 8th revision.
Acidum sulphuricum aromaticum.	H_2SO_4, by weight	About 18.5 per cent	About 20.0 per cent.
Aconitum.	Aconitin, by weight	Standard not fixed	At least 0.5 per cent.
Alcohol dilutum	Absolute alcohol, by weight	About 41.0 per cent	About 41.5 per cent.
Belladonnæ folia	Mydriatic alkaloids, by weight	Standard not fixed	At least 0.35 per cent.
Belladonnæ radix.	Mydriatic alkaloids, by weight	*Standard not fixed*	*At least* 0.5 per cent.
Caffeina citrata effervescens	Citrated caffein, by weight	2.0 gm. in 100 gm.	4.0 gm. in 100 gm.
Cinchona.	Alkaloids, by weight	At least 2.5 per cent. quinin	At least 4 per cent ether-soluble alkaloids.
Coca.	Ether-soluble alkaloids, by weight.	Standard not fixed	At least 0.5 per cent.
Colchici cormus	Colchicin, by weight	Standard not fixed	At least 0.35 per cent.
Colchici semen	Colchicin, by weight	Standard not fixed	At least 0.55 per cent.
Conium.	Conlin, by weight	Standard not fixed	At least 0.5 per cent.
Emplastrum belladonnæ	Mydriatic alkaloids, by weight	Standard not fixed	From 0.38 to 0.42 per cent.
Extractum balladonnæ	Mydriatic alkaloids, by weight	Standard not fixed	0.3 per cent.
Extractum colchici cormi	Colchicin, by weight	Standard not fixed	1.4 per cent.
Extractum hyoscyami	Mydriatic alkaloids, by weight	Standard not fixed	1.4 per cent.
Extractum nucis vomicæ	Strychnin, by weight	15.0 per cent. total alkaloids	5.00 per cent.
Extractum opii	Morphin (cryst.), by weight	18.0 per cent.	20.00 per cent.
Extractum physostigmatis	Ether-soluble alkaloids, by weight.	Standard not fixed	2.0 per cent.
Extractum stramonii	Mydriatic alkaloids, by weight	Standard not fixed	1.4 per cent.
Fluidextractum aconiti	Aconitin, by weight	Standard not fixed	0.4 gm. in 100 c.c.
Fluidextractum belladonnæ radicis	Mydriatic alkaloids, by weight	Standard not fixed	0.5 gm. in 100 c.c.
Fluidextractum cinchonæ	Anhydrous e.-s. alkaloids, by wt.	Standard not fixed	4.0 gm. in 100 c.c.
Fluidextractum cocæ	Ether-soluble alkaloids, by weight.	Standard not fixed	0.5 gm. in 100 c.c.
Fluidextractum colchici seminis	Colchicin, by weight	Standard not fixed	0.5 gm. in 100 c.c.
Fluidextractum conii	Conlin, by weight	Standard not fixed	0.45 gm. in 100 c.c.
Fluidextractum guaranæ	Alkaloids, by weight	Standard not fixed	3.5 gm. in 100 c.c.
Fluidextractum hydrastis	Hydrastin, by weight	Standard not fixed	2.0 gm. in 100 c.c.
Fluidextractum hyoscyami	Mydriatic alkaloids, by weight	Standard not fixed	*0.075 gm. in 100 c.c.*
Fluidextractum ipecacuanhæ	Alkaloids, by weight	Standard not fixed	1.75 gm. in 100 c.c.
Fluidextractum nucis vomicæ	Strychnin, by weight	1.5 gm. total alkaloids in 100 c.c.	1.0 gm. in 100 c.c.
Fluidextractum pilocarpi	Alkaloids, by weight	Standard not fixed	0.4 gm. in 100 c.c.
Fluidextractum stramonii	Mydriatic alkaloids, by weight	Standard not fixed	0.35 gm. in 100 c.c.
Guarana	Alkaloids, by weight	Standard not fixed	*At least 3.5 per cent.*
Hydrastis	Hydrastin, by weight	Standard not fixed	At least 2.5 per cent.
Hyoscyamus	Mydriatic alkaloids, by weight	Standard not fixed	At least 0.08 per cent.
Ipecacuanha	Alkaloids, by weight	Standard not fixed	At least 2.0 per cent.
Jalap	Alcohol-soluble resin, by weight	12 per cent.	At least 8.0 per cent.
	Ether-soluble resin, by weight	Not more than 1.2 per cent.	*Not more than 1.5 per cent.*
Liquor ferri chloridi	Anhydrous $FeCl_3$, by weight	37.8 per cent.	29.0 per cent.
Liquor ferri et ammonii acetatis.	Tincture of ferric chlorid	2 c.c. in 100 c.c.	4 c.c. in 100 c.c.
Liquor ferri tersulphatis	$Fe_2(SO_4)_3$, by weight	28.7 per cent.	36.0 per cent.
Lithii citras effervescens	Lithium citrate, by weight	About 17.0 per cent	*About 5.0 per cent.*
Nux vomica	Strychnin, by weight	*Standard not fixed*	*At least 1.25 per cent.*
Oleatum hydrargyri	Yellow mercuric oxid, by weight.	20.0 per cent.	25.0 per cent.
Oleum amygdalæ amaræ	Benzaldehyd, by weight	Standard not fixed	At least 85 per cent.
	Hydrocyanic acid, by weight	Standard not fixed	2 to 4 per cent.
Oleum cajuputi	Cineol, by volume	Standard not fixed	At least 55 per cent.
Oleum caryophylli	Eugenol, by volume	*Standard not fixed*	*At least 80 per cent.*
Oleum cinnamomi	Cinnamic aldehyd, by volume	Standard not fixed	At least 75 per cent.
Oleum eucalypti	Cineol, by volume	Standard not fixed	At least 50 per cent.
Oleum limonis	Citral, by weight	Standard not fixed	At least 4 per cent.
Oleum menthæ piperitæ	Menthyl acetate, by weight	Standard not fixed	At least 8 per cent.
	Total menthol, by weight	*Standard not fixed*	*At least 50 per cent.*
Oleum pimentæ	Eugenol, by volume	Standard not fixed	At least 65 per cent.
Oleum rosmarini	Bornyl acetate, by weight	Standard not fixed	At least 5 per cent.
	Total borneol, by weight	Standard not fixed	At least 15 per cent.
Oleum santali	Santalol, by weight	Standard not fixed	At least 90 per cent.
Oleum thymi	Phenols, by volume	*Standard not fixed*	*At least 20 per cent.*
Opii pulvis	Morphin (cryst.), by weight	13 to 15 per cent	12 to 12.5 per cent.
Opium deodoratum	Morphin (cryst.), by weight	13 to 15 per cent	12 to 12.5 per cent.
Physostigma	Ether-soluble alkaloids, by weight.	Standard not fixed	At least 0.15 per cent.
Pilocarpus	Alkaloids, by weight	Standard not fixed	At least 0.5 per cent.
Potassii citras effervescens	Potassium citrate, by weight.	*About 48.0 per cent*	*About 20.0 per cent.*
Stramonium	Mydriatic alkaloids, by weight	Standard not fixed	At least 0.35 per cent.
Suppositoria glycerini	Glycerin (half their former size)	6 gm. each	3 gm. each.
Syrupus ferri iodidi	Ferrous iodid, by weight	About 10 per cent.	About .5 per cent.
Tinctura aconiti	Aconitin, by weight	Standard not fixed	0.045 gm. in 100 c.c.
	Aconite	1 gm. in 2.85 c.c.	*1 gm. in 10.0 c.c.*
Tinctura belladonnæ foliorum	Mydriatic alkaloids, by weight	Standard not fixed	0.035 gm. in 100 c.c.
	Belladonna leaves	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
Tinctura benzoini composita	Benzoin	1 gm. in 8.33 c.c.	1 gm. in 10.0 c.c.
Tinctura cannabis Indicæ	Indian cannabis	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
Tinctura cantharidis	Cantharides	1 gm. in 20.0 c.c.	1 gm. in 10.0 c.c.
Tinctura capsici	Capsicum	1 gm. in 20.0 c.c.	1 gm. in 10.0 c.c.
Tinctura cardamomi	Cardamom	1 gm. in 10.0 c.c.	1 gm. in 5.0 c.c.
Tinctura cinnamomi	Saigon cinnamon	1 gm. in 10.0 c.c.	1 gm. in 5.0 c.c.
Tinctura colchici seminis	Colchicum seed	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
	Colchicin, by weight	Standard not fixed	0.05 gm. in 100 c.c.
Tinctura digitalis	Digitalis	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
Tinctura ferri chloridi	Anhydrous $FeCl_3$, by weight	13.6 per cent., by weight	13.28 per cent., by weight.
Tinctura gambir composita	Gambir	1 gm. in 10.0 c.c.	1 gm. in 20.0 c.c.
Tinctura gelsemii	Gelsemium	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
Tinctura hydrastis	Hydrastin, by weight	Standard not fixed	0.4 gm. in 100 c.c.
Tinctura hyoscyami	Mydriatic alkaloids, by weight	Standard not fixed	0.007 gm. in 100 c.c.
	Hyoscyamus	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
Tinctura kino	Kino	1 gm. in 10.0 c.c.	1 gm. in 20.0 c.c.
Tinctura lobeliæ	Lobelia	1 gm. in 5.0 c.c.	1 gm. in 10.0 c.c.
Tinctura nucis vomicæ	Strychnin, by weight	0.3 gm. *total alkaloids* in 100 c.c.	0.1 gm. strycvhnin in 100 c.c.
Tinctura opii	Morphin (cryst.), by weight	1.3 to 1.5 gm. in 100 c.c.	1.2 to 1.25 gm. in 100 c.c.
Tinctura opii deodorati	Morphin (cryst.), by weight	1.3 to 1.5 gm. in 100 c.c.	1.2 to 1.25 gm. in 100 c.c.
Tinctura physostigmatis	Physostigma	1 gm. in 6.67 c.c.	1 gm. in 10.0 c.c.
	Ether-soluble alkaloids, by weight.	Standard not fixed	0.014 gm. in 100 c.c.
Tinctura quassiæ	Quassia	1 gm. in 10.0 c.c.	1 gm. in 5.0 c.c.
Tinctura rhei	Rhubarb	1 gm. in 10.0 c.c.	1 gm. in 5.0 c.c.
Tinctura sanguinariæ	Sanguinaria	1 gm. in 6.67 c.c	1 gm. in 10.0 c.c.
Tinctura scillæ	Squill	1 gm. in 6.67 c.c	1 gm. in 10.0 c.c.
Tinctura stramonii	Stramonium	1 gm. in 6.67 c.c	1 gm. in 10.0 c.c.
	Mydriatic alkaloids, by weight	Standard not fixed	0.03 gm. in 100 c.c.
Tinctura strophanthi	Strophanthus	1 gm. in 20.0 c.c.	1 gm. in 10.0 c.c.
Tinctura tolutana	Balsam of tolu	1 gm. in 10.0 c.c.	1 gm. in 5.0 c.c.
Tinctura veratri	Veratrum	1 gm. in 2.5 c.c.	1 gm. in 10.0 c.c
Trochisci cubebæ	Oleoresin of cubeb, by weight	0.25 gm. in each	0.125 gm. in each.
Unguentum chrysarobini	Chrysarobin, by weight	About 5.0 per cent	About 6.0 per cent.
Unguentum phenolis	Phenol, by weight	About 5.0 per cent	About 3.0 per cent.
Unguentum sulphuris	Washed sulphur, by weight	About 30.0 per cent	About 15.0 per cent.

son, China would be a magnificent opening for them. It would also be a great benefit to China, for are not patent medicines valuable remedies, and is it not cruel to deprive any people of them? By all means, let the patent medicine men work the Chinese for a while, if that long-suffering people will stand for it.

An Early Patent Medicine Fraud.

According to a correspondent of the New York *Evening Post*, probably the earliest instance of drastic "treatment" of the patent-medicine fraud in this country is recorded in "The New England Chronology," Part II, 2 (1,754), of the Rev. T. Prince (Arbor's English Garner, ii, 577-578):

"March 4 (1631). First Court of Assistants this year, at Boston. Present, Governor, Deputy Governor, Sir R. Saltonstall, Master Ludlow, Captain Endicot, Masters Pynchon, Novell, Sharp, Coddington, Bradstreet.

"Ordered. . . . A man fined £5, for taking upon him to cure a scurvy, by a 'Water' of no value; which he sold at a very dear rate; to be imprisoned till he pay his fine, or give security for it; or else be whipt. And shall be liable to any man's action, of whom he has received money for the said 'Water.'"—*American Medicine*, Nov. 18, 1905.

Will Help Honest Advertising.

Those who are a bit nervous over the exposure of the patent-medicine industry by popular magazines should remember that the campaign is directed chiefly against mendacious patent-medicine advertising. Surely no fault can be found with a crusade against lying advertisements. If it were possible to eliminate falsehood from all advertising it would be the best thing that ever happened to the honest advertiser. To-day the man who sticks to the plain truth in his advertisements suffers from the monumental prevarication of less conscientious advertisers who have deceived the public so much that it liberally discounts the utterances of all advertisers except in those isolated cases where experience has shown that one may be believed. Good honest advertising will sell a good honest medicine, and if it doesn't the fault is not with the advertising.

The above is from the *New Idea*, the house organ of Frederick Stearns & Co. What is said here in regard to "patent medicines" applies exactly to proprietaries advertised to physicians. It is the lying, the absurdly extravagant claims, the false statements regarding both the composition and the therapeutic action of the articles, that has brought all proprietaries into disrepute among many physicians. Of course, if the whole truth were written about many proprietaries, it would spell humbug, but there are plenty of valuable proprietaries which would win favor if the straight honest truth were told about them.

Practical Work Outlined by Chicago Medical Society.

At the regular monthly meeting, held December 12, the Council of the Chicago Medical Society unanimously adopted the following resolutions:

1. That every branch of the society be requested to set aside an evening for the discussion of this question and particularly to encourage the members to report data in regard to cases observed which were injured or killed by the use of patent medicines.
2. That the secretaries of the branch societies be requested to send this material to the Public Relations Committee.
3. That the council appoint a committee to prepare articles on this subject for the lay press; this committee also to prepare and supply the lay press with other matter on this same subject for publication.
4. That THE JOURNAL of the American Medical Association be requested to prepare reprints of the articles on proprietary medicines and of the articles in *Collier's Weekly*, and that the society should set aside sufficient funds to furnish each doctor in the county with a copy of these reprints.
5. To have run in the *Bulletin* a request for the data of cases observed by the members of the society, who have been or may be injured by the use of patent medicines.
6. That a committee be appointed to see if the *Daily News* will accept a lecture on the patent medicine question to be inserted in their lecture column.
7. To communicate with the president of the state society in regard to above suggestions, and such others as may be made by the council, and request him to communicate with the various county societies and request them to encourage the same work.

Southwestern Branch Indorses Movement.

On account of the numerous and rapidly increasing number of worthless and harmful preparations that are being exploited among the physicians of the land, be it

Resolved, That the Southwestern Branch of the Chicago Medical Society expresses its hearty approval of the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry to investigate non-official drugs and medicinal preparations. It also approves the action of THE JOURNAL of the American Medical Association in its campaign of educating the medical profession concerning the evils of nostrums and urges it to continue in the good work. It also heartily commends the action of *Collier's Weekly* and *Ladies' Home Journal* in exposing the evils of patent medicines, and be it also.

Resolved, That each member of this society be requested to write to the editors of these publications commending the action they have taken in the matter, and also that a copy of these resolutions be spread on the minutes of the society and that copies be forwarded to the secretary of the Chicago Medical Society, editor of THE JOURNAL of the American Medical Association, *Collier's Weekly* and *Ladies' Home Journal*. C. HUBART LOVEWELL, Secretary.

Resolutions Indorsing the Fight Against Nostrums.

At a recent meeting, the Lackawanna County (Pa.) Medical Society passed resolutions commending the work of *Collier's Weekly* and of the *Ladies' Home Journal* in their campaign against "patent medicines." At its December meeting, the Shiawasse County (Mich.) Medical Society adopted resolutions indorsing the action of THE JOURNAL A. M. A., *Collier's Weekly*, and the *Ladies' Home Journal* in exposing the methods of the Proprietary Association.

As Collier's Sees It.

BEWARE
OF
ACETANILID

The following well-known "remedies," both "ethical" and "patent," depend for their results upon the heart-depressing action of Acetanilid:

Orangeine
Bromo-Seltzer
Royal Pain Powders
Miniature Headache Powders
Megrimine
Anti-Headache
Dr. Davis's Headache Powders
Antikamnia
Ammonol
Salacetin
Phenalgin
Cephalgin

and practically all of the drug-store-vended "headache cures" and "anti-pain" remedies.

Take no nostrum of this class without a doctor's prescription, unless you are sure it contains no acetanilid. Make the druggist tell you. He is responsible. A suit for damages has recently been won against a New York drug store for illness consequent upon the sale of a "guaranteed harmless" headache tablet containing three grains of acetanilid.

[The above is from *Collier's Weekly*. It is certainly unkind to mix such ethical and well-established compounds as antikamnia, salacetin, phenalgin and ammonol with common every-day "patent medicines," as is done in this instance!]

New Chemical Remedies in Switzerland.

The Swiss Association of Pharmacists has recently passed, at its general meeting, what seems to us a timely and beneficial resolution. It recommends that each manufacturer be compelled to publish on the label of each pharmaceutic product the [illegible] st, its chemical name, as well as its com- [illegible] second, its reactions (of identity), its [illegible] boiling point, and its solubility in ordinary solvents; third, its dosage. There are already so many comparatively new chemical remedies and they are being added to so frequently and constantly that pharmacists can not be posted as to their physical characteristics and their properties, hence they can not, without the information above mentioned, exercise the proper control as to their purity or their safe administration.—Editorial in *New Orleans Medical and Surgical Journal.*

Not Under the Red Clause.

We have before urged that newspapers, as a rule, even to the extent of self-sacrifice, would come out on the side of right if the facts were placed before the editors in a way to show them what is right. It has been surprising to those who have watched the trend of affairs since the publication of *Collier's* article on the "Patent Medicine Conspiracy Against the Freedom of the Press" to note that the Press Committee of the Proprietary Association has not been able to control all of the newspapers. On the other hand, a large number have come out boldly and have sided with the public in this propaganda against frauds in "patent medicines." Every day fresh evidence of this is coming to our attention. We know it to be a fact, also, that many newspapers that have not come out openly on either side have refused to use matter supplied them by the Press Committee of the Proprietary Association. The following are samples of editorial comments in the newspapers:

The *Lincoln Trade Review*, December 2, says: "There is no graft in operation to-day that reaches so deeply into the pocketbooks of individuals and gives absolutely so little in return as the sale of numerous 'patent medicines' which prove, on examination, to be unmitigated frauds of the first water. One of the regrettable things in this connection is the way they are advertised and the part that newspapers play in duping the public by publishing the remarkable statements of cures that these frauds are alleged to make."

The *Seattle* (Wash.) *Star* makes the following manly announcement:

> "Eleven different patent medicines, which have been regularly advertised in the columns of the *Seattle Star*, will no longer be accorded space in this newspaper. . . . .
>
> All advertising arrangements made by this paper are subject to editorial control. The editor can *determine what matter offered by* advertisers is fit to print and what is not fit to print.
>
> The *Star's* editor has determined that objectionable matter lies *in most* patent medicine ads. and that they are therefore subject to refusal.
>
> The *Star* desires to be consistent in its crusade against patent medicines as a class. It does not seem right for the paper to accept profits from advertisements of articles which it denounces editorially, and which it believes should not be sold to the people.
>
> The fact that there is considerable pecuniary loss involved as a result of the elimination of these ads. can not be considered for a *moment*.

This is certainly clear cut, and the editor has taken a firm stand. He further says that the *Star* does not claim to be able to protect the people against all sorts of fakes, but he considers it his simple duty to take the stand here outlined because the line between right and wrong appears to him so clearly drawn.

Correspondence

The Removal of Liquor from the Army Canteen.

Pueblo, Colo., Dec. 14, 1905.

To the Editor:—In a recent issue of the *Medical Record*, the editor takes up the question of the army canteen. The argument advanced is the same old story. The editor of the *Record*, as a scientific man, should be more exact in some of his statements. Congress did not pass an act closing the canteens; the act prevented only the sale of liquor in military reservations, etc. The store department, the post exchange, the reading room, the recreation room, remain the same.

I have seen something of the army life in the Orient, and I wish to say, as a physician and a citizen, that every boy in the army is infinitely better off without the beer halls than with them. It is true, some men will go to outside saloons for their drinks, but they will not go so often and they will not drink as much when they have to go from one to three miles as if they could get it in the camp. Then, too, it helps to save the enlisted man who has not begun to drink. It gives him a much better chance to let it alone when there is none to be found in the army canteen.

There are other causes for desertion, and many of them, apart from those given by the *Record*.

The following statement is made by Gen. Noel Gaines, an old army officer:

> "The truth is, the inability of the soldiers easily to obtain liquor is *not* the cause of the increased desertions and poor discipline and ill-content of the men; but rather the low standard of morals of men and officers, growing out of drinking intoxicating liquors in any form, whereby their *morality*, sense of honor and patriotism are gradually destroyed; coupled with the *tyrannical treatment* of the enlisted men (all of whom are Americans and will not tolerate *tyranny*) *by almost the* whole of the younger officers of the army, *and a* great many of the older ones, are real *causes*. I *testify* to this from personal observation."

Lieut. Gen. Nelson A. Miles, just two years ago, after almost three years' trial of the prohibition of liquor in army reservations, had this to say:

> "*For a long* times the army has been without what is known as the liquor *feature of* the canteen. The army posts are much better off without it, I find. That element having once been discarded it would be an injury and a step backward to reintroduce it.
>
> "The *canteen, so-called*, is a recreation room or building established or set apart at nearly all military posts. It is for the comfort of the enlisted men.
>
> "It *includes the recreation* room which gives the men opportunity for social intercourse, the playing of games and the *reading of magazines and books*. *It* also affords them light refreshment of various *kinds which they may desire* in addition to the good, wholesome food furnished by the government.
>
> "There are certain men in the service, as in every community, who will have *liquor if it is possible* to obtain it. Of course these are not the best men in the ranks.
>
> "But now that liquor has been removed from the military reservations *those not addicted to the use of liquor* are free from its demoralizing influences. The temptation to use it is made very remote.
>
> "Besides, *the amusements rooms* where the men *who desire may* study or read or have orderly recreation are not disturbed by men wholly or partly under the influence of liquor. In other words, the canteen is made inviting to decent, *self-respecting men*.
>
> "I have visited many posts during the past year, and I know that the conditions are better now than ever before. This I say positively *from my own observation*.
>
> "At one large post in the West the present canteen is so well conducted and so well patronized that it has paid dividends of $1 a month to every man. This shows that the argument that the canteen can not be sustained without the liquor feature is wholly false.
>
> " 'Do you think, General, that there is less drunkenness among the soldiers than existed when the canteen had the liquor feature?'
>
> " 'I know there is less,' " was General Miles' emphatic reply.—*Boston Advertiser*, Dec. 12, 1903.

It is time for sensible men, and especially physicians, to give up the fallacy that soldiers must get drunk. I have seen army officers passing through hostile territory so drunk that a sudden attack could have ended in nothing but defeat. Boys who enlist in the army because they can get liquor are poor defenders of their country, and, if they leave the army because they can not get it, it is small loss.

Lord Kitchener, in the campaign of the Soudan, abolished liquor of all kinds, even from the officers' mess. Their liquid refreshments were confined to tea and oatmeal water. This was on no temperance grounds, but because he knew the powers of endurance could be maintained without liquor better than with it. His forced marches over burning sand and his victory of Omdurman proved his conclusions correct. Japan has recently shown the world the advantage of a sober army. A. S. Barker has this to say of excluding wines and beers from ship canteens:

> "The navy is to be congratulated that the department has remained firm in excluding wine and beer from the canteen of ships.
>
> "Railroad companies do not employ men who drink intoxicating liquor because of the increased danger of accidents and consequent claims for damages.
>
> "Manufacturing concerns are yearly becoming more strict in this regard. How much greater the necessity for absolute sobriety on a battleship? Tons of explosives are confined in the vessel, fires burn with intense heat in the furnaces, electricity is generated in currents of sufficient strength to run 1,000 lamps and move turrets weighing hundreds of tons, while within the ship closely housed over this dormant hell are more than 700 human beings.
>
> "The majority of enlisted men come from good homes and are temperate. Is it therefore not better to weed out the few intemperate and raise the standard still higher than to disgust many self-respecting men and lower the tone of the service?
>
> "A. S. Barker,
> "Rear Admiral, U. S. Navy.
> "Commander-in-Chief North Atlantic Fleet."

One of the inconsistencies, in which those who want to place the beer halls back in the army camps indulge, is this: They say: Drunkenness has increased; desertion has decreased. Yet, in the same article, they will go on to tell us that men are leaving the army because they can not get liquor. The fallacy is evident. Beer and cigarettes are not the rations of any great football team, and every physician knows that they are equally poor for fighting men.

Let some army officers try as hard to keep the boys from drinking, both by precept and example, as they do now to restore liquor to the army canteens, and we will hear less about the need of it. The result of no beer saloons in the navy is attracting to our navy a better class of men. On one ship alone, in the paymaster's safe, there is over $33,000 saved by the men on board. This does not occur on board beer-hall ships. According to the official report of the U. S. Navy, the health of the men is better and the death rate less. There are no medical reasons for returning to the old régime in either army or navy.

John Inglis.

The Burning of the Books.

South Haven, Mich., Dec. 18, 1905.

To the Editor:—I have just read the letter of Dr. B. Holmes in The Journal of Dec. 16 on the "Burning of Books," and I must enter a protest against such wholesale denunciation of all medical books older than the last edition. To my mind, the fathers in medicine, be they old or new, deserve not only our respect, but their teachings and their books are worthy of our serious thought and study. There is something more due them and ourselves than—

"As dutious sons we fondly wished
Our fathers were more wise."

Truth is not always most abundant in things ultra new. There is no greater danger of falling into error by going slow than by going too fast.

The same desire of the public which demands two editions of a daily paper, with extras between, seems to consume some medical men, and they court and receive the distinction of being on the crest of the wave of "the very latest." The public may applaud and flock to them, but it does not follow that their patients are cured or helped by them more than by the more conservative practitioner. There are fads and fancies in things medical, as well as in other lines of human activity. It is the mad desire for something new that drives men to follow after such strange gods as osteopathy, Eddyism, and their like.

The man in general practice can not and should not attempt to keep abreast with the man in the laboratory devoting himself to experimental and original research work.

Fifty thousand of the "60,000 physicians" spoken of by Dr. Holmes can not buy the last editions of all needed medical text-books, nor is it necessary, in my humble opinion, that they should do so in order to be up with the times in their work. Nor do they need to burn or even to discard all save the last editions.

It is often astonishing how little "revising" is required for an excuse for a "new edition." The changes more often consist of an increased number of "plates" rather than new or revised ideas.

Let not the physician be ashamed to have good standard medical books on his shelves, though part of them, at least, be not the very last revision.

The man who subscribes for and faithfully reads a few good current medical journals need not fear that his patients will suffer for lack of modern treatment, even if some of his text-books are two or even ten years old.

L. G. Rhodes, M.D.

Roentgen Rays in Dentistry.

Chicago, Dec. 18, 1905.

To the Editor:—In reference to the article with the above title by Dr. Kassabian in the issue of December 16, permit me to make a few remarks about the technic employed, which, I think, will be of value to every Roentgenologist. As to the material used, I find heavily coated celluloid paper the ideal material for such work. I cut pieces 2 x 3 cm., inclose them in oiled paper, and cover them with black paper, the smooth side of the cover corresponding with the emulsion side of the film.

I place the patient on a table and, according to the advice of Albers-Schonberg (*Die Roentgentechnik*, Hamberg, 1903), either let the patient adduct his chin as near as possible to his chest (upper jaw) or bend it as far as possible backward (lower jaw). By this position it is much easier to direct the rays as nearly perpendicular as possible to the film, and a distortion will never occur. The film is then inserted, held in place by an assistant or the patient himself, the point of pressure being, of course, as Dr. Kassabian says, on the particular tooth to be Roentgenographed. The results I have thus obtained are most satisfactory. This same method is used, also, in locating stones in the salivary ducts, the film being inserted over the tongue, the head held backward at right angle to the spinal column and the rays directed perpendicular to the floor of the mouth. I reserve the extra-oral Roentgenography of teeth for the third molar only, and then use a very small lead diaphragm, which helps me greatly in getting a perfect picture of the tooth.

Max Reichmann, M.D.

The Nomenclature of Proprietary Medicines.

New York, Dec. 11, 1905.

To the Editor:—Your issue of December 9 contains an article by Prof. C. S. N. Hallberg on the above subject, from which we quote the following:

> And yet, in the face of this undeniable awakening of medical men, a firm of chemists of the highest standing has recently devised the meaningless, empiric names for three articles of its manufacture: Duotonol tablets, quartonol tablets, sextonol tablets.
>
> "Tonol" stands for glycerophosphates, and the prefixes refer to one number of different kinds of glycerophosphates, salts of alkalies, contained in each tablet. Now these names have been devised on the assumption that physicians will appreciate them, owing to their brevity and euphony; on the other hand, it is evident that these names will not appeal to the thinking physicians, as they would under the pharmaceutical titles, with the name of the illustrious founder of the firm as the trademark.

We beg leave to state here the considerations which led us to the adoption of the names challenged by your distinguished contributor:

We were the original introducers of the glycerophosphates in this country and extensively advertised them among the medical profession during the past decade. But soon after these salts had met with a favorable reception they were also marketed by other firms. The latter were able to undersell us because they had had none of the enormous costs and risks connected with the introduction, and, besides, some of the competitive preparations had shortcomings in purity and stability.

After advertising these salts as "glycerophosphates-Schering" for eight years—as Prof. Hallberg advises—we were in self-protection forced to adopt the trademark "tonol." The physician, by using this short and easily-remembered name, was thereby enabled to assure the dispensing of Schering's glycerophosphates.

The name "duotonol" was given to the lime-soda combination, "quartonol" to the tablet containing four salts, and "sextonol" to the one of six salts. It would hardly have been possible to devise names less subject to confusion. If the combinations had been designated "No. 1," "No. 2" and "No. 3," many physicians would have been unable to recall, when prescribing, which of the three numbers represented the tablet desired. And "Schering's tablets of glycerophosphates of lime, sodium, iron, manganese, quinin and strychnin" (instead of sextonol) would have presented equally great mnemonic difficulties. But in addition we always state in our advertisements, our literature, and on the labels of the packages, the name of Schering in connection with the formulas.

We are confident that the tradenames will recommend themselves by their precision and convenience, and indeed, we already possess proof of this fact.

While we regretfully recognize the fact that there is a multiplicity of brands of proprietary medicines, the same is true of all pharmaceuticals; the druggist often has to keep in stock several brands of morphin, quinin, etc. In the case of proprietary preparations, however, the remedy is obvious, if the physician will specify the original product, whose manufacturer deserves the reward of his labors and who may be relied on to supply the product of highest quality. If the physician leaves the selection of the brand to the pharmacist, cheapness —not quality—will often determine whose product is selected, and the cheapest is most likely the poorest one.

Schering & Glatz.

Infant Consultations.

Philadelphia, Dec. 1, 1905.

To the Editor:—Reading your notice of the Congress of "Gouttes de Lait," I would like to call your attention to the fact that there has been started in Philadelphia within the last two months a little hospital under the name of The Christ's Hospital, whose work is the same as those European stations. The purpose of the clinics is to allow mothers to bring their babies to have their diet, hygiene and general care supervised by competent medical men. The question of milk supply is a vital one, and advice to the mothers on milk mixtures is very important. You note on p. 1747 that some of these stations do not survive; it requires an infinite patience to deal with some of the more ignorant mothers. Many of them have been brought up *in a mill, and have faint ideas about housekeeping.* They do not know how to make the best of their limited resources. The proportion of waste and needless expenditure among the poor is apt to be greater than among the *gens doré* of our social structure.

This work in Philadelphia is called by the name of child registration and, although just begun, seems to have a future. At other hours there are clinics for the treatment of diseases of children, but the hour of registration is strictly one for normal study. Valuable statistics of height, weight, nutrition, and general development will be obtained, and in the changes of childhood there is the chance to know better how adult processes become initiated. The address of the hospital is 3354 North Front street, where any correspondence with those interested will be welcome.

The institution has its finances guaranteed by the St. Ambrose P. E. Mission and the Providence M. E. Church, as well as by public-spirited individuals of the neighborhood. It seems a very relevant work for religious bodies to assist, and in the future it may be that more of this charity will find issue in their activities. T. H. Evans, M.D.

Marriages

Arthur K. Hammond, M.D., to Mrs. Keller, both of Fort Wayne, Ind.

Jaros F. Zivnuska, M.D., to Miss Flora A. Salentine, both of Milwaukee, Wis.

Ralph Butler, M.D., to Mrs. John E. Shaw, both of Philadelphia, December 18.

S. Baskin Sherard, M.D., Iva, S. C., to Miss Mattie Moson, at Baltimore, December 5.

John H. McCutchan, M.D., to Miss Maude Earle, both of Evansville, Ind., December 6.

Alexander S. Sim, M.D., to Miss Lorna Lucy Lyons, both of Brooklyn, N. Y., December 7.

Moses Eisenstaedt, M.D., to Miss Blanche Janet Benjamin, both of Chicago, December 18.

Merle Flenner, M.D., Hamilton, Ohio, to Miss Adrienne Nosler of Chicago, December 12.

Derostus E. Smith, M.D., to Miss May Milehan, both of Kansas City, Kan., December 6.

John L. Seay, M.D., Sumterville, Ala., to Miss Lizzie Clark of Pratt City, Ala., December 5.

Walter S. Wing, M.D., to Miss Laura Casper, both of Oconomowoc, Wis., November 29.

Livingston L. Shropshire, M.D., to Miss Agnes James, both of San Antonio, Texas, November 27.

Eugene G. Holden, M.D., Caldwell, Idaho, to Miss Ethel Kuppinger of Erie, Colo., December 6.

George Ingles Macleod, M.D., Ardmore, Pa., to Miss Madge Twiggs of Augusta, Ga., December 17.

George M. Shaw, M.D., Robinsonville, Miss., to Miss Lulu Rhea of Somerville, Tenn., December 6.

John J. Travis, M.D., Northport, Wash., to Miss Alice J. Bowes of Spokane, Wash., November 23.

Charles H. Zorger, M.D., Ivesdale, Ill., to Miss Anna Cecilia Sunderland of Urbana, Ill., November 28.

John Crayke Simpson, M.D., to Miss Louise Kauffmann, both of Washington, D. C., December 12.

J. Austin Thompson, M.D., to Mrs. Allie McCreedy, both of Letts, at Washington, Iowa, November 29.

Samuel H. Heavrin, M.D., Louisville, Ky., to Miss Stella Rothschild of Owensboro, Ky., December 6.

Samuel T. Glasford, M.D., to Miss Marie Clark, both of Danvers, Ill., at Peoria, Ill., November 29.

Arne A. Stemsrud, M.D., Dawson, Minn., to Miss Minnie Lindell of Grove City, Minn., November 29.

Harry G. Templeton, M.D., Plymouth, Pa., to Miss Anna Blanchard of Wilkesbarre, Pa., November 26.

Joseph Henry Delaney, M.D., Bozeman, Mont., to Miss Nina Howell White of Hobgood, N. C., December 19.

Ernest Ray Limbocker, M.D., New Virginia, Iowa, to Miss Gertrude Vera Salber of Clarinda, Iowa, November 30.

Albert F. Zimmermann, M.D., Santa Ynez, Cal., to Miss Virginia Claire Bradley of Los Angeles, Cal., November 29.

Eugene Byron Glenn, M.D., Asheville, N. C., to Miss Elizabeth Elliott Lumpkin of Columbia, S. C., December 21.

Albert Livingston Stavely, M.D., Washington, D. C., to Miss Willie Browning Haralson of Montgomery, Ala., December 6.

Deaths

William S. Forbes, M.D.

William S. Forbes, M.D. Jefferson Medical College, Philadelphia, 1852, died suddenly at his home in Philadelphia, from angina pectoris, December 17, aged 74. Dr. Forbes served for one year as assistant surgeon in the English service during the Crimean War. He also served as resident physician in the Pennsylvania Hospital, and later taught private classes in surgery and anatomy in the College of Anatomy, Philadelphia. He was a member of the Academy of Natural Sciences, College of Physicians of Philadelphia, Philadelphia County Medical Society, Medical Society of the State of Pennsylvania, and American Surgical Association. He served throughout the Civil War as surgeon in the United States Volunteers, was appointed medical director of the Thirteenth Army Corps and served under General Grant during the siege of Vicksburg. He was surgeon to the Episcopal Hospital for 25 years, and also surgeon to the Jefferson Medical College Hospital. In 1879 he was made demonstrator of anatomy in Jefferson Medical College, and in 1886, he was appointed professor of anatomy, and held that chair until his death. Perhaps the crowning act of Dr. Forbes' life and the deed of which he was most proud was his authorship of the *original Anatomy Act of Pennsylvania* in 1863, and its amendment in 1883. This act has placed the procuring of subjects for dissection in the various medical schools in Pennsylvania on a legal basis, and has been of the greatest aid in the advancement of medical science. This act is the prototype and has been copied by all of the states in the union. He was the inventor of a new lithotrite and method of obtaining and measuring the strength of these instruments and the measured crushing resistance of vesical calculi. *blood from the arteries to the veins,* "Per Perositates," *and* an article on the diaphragm as a protector of the heart, and its influence in changing the current of blood, at birth, from the ductus arteriosus, to the lungs, by compressing the ductus arteriosus until the lumen of the duct is obliterated. He devised and was the first to perform the operation of liberating the ring finger of musicians by dividing the accessory tendons of the common extensor of the digits. At *the 1905 com*mencement exercises of Jefferson Medical College a life-size portrait of Dr. Forbes was presented to the board of trustees of the college by the students and alumni. At the same time the Alumni Association of the University of Pennsylvania presented him with a silver loving-cup in recognition of his services in securing the establishment of the present state anatomic law. Dr. Forbes was an eloquent and sincere teacher and loved by all students who came in contact with him. He was known by the students in Jefferson as "the grand old man."

George Warner Miltenberger, M.D. University of Maryland School of Medicine, Baltimore, 1840; demonstrator of *anatomy in* that institution from 1840 to 1847; lecturer on pathology from 1847 to 1852; professor of materia medica and pathologic anatomy from 1852 to 1858; professor of obstetrics from 1858 to 1891; dean of the faculty from 1855 to 1869; emeritus *pro*fessor of obstetrics and honorary president of the faculty of his alma mater since 1891; president of the Baltimore Obstetrical and Gynecological Society in 1885-1886, and of the Medical and Chirurgical Faculty of Maryland 1886-1887; consulting physician to Johns Hopkins Hospital; one of the oldest and most highly esteemed practitioners of Baltimore, died at his home in that city from senile debility, December 11, aged 86. In 1896 his portrait was presented to the Medical and Chirurgical Faculty of Maryland. He led a strenuous professional life, and gave to the University of Maryland the best of his life and service.

George S. Hyde, M.D. Harvard University Medical School, Boston, 1856; a member of the American Medical Association, Massachusetts Medical Society, Suffolk District Society and Harvard Medical Alumni Association; interne at the Massachusetts General Hospital; a practitioner of Boston for half a century; for 40 years physician to St. Vincent's Orphan Asylum; prominent in all charitable work, died at his home in Boston, December 11, aged 74.

John F. Failing, M.D. University of Buffalo (N. Y.) Medical Department, 1868; a veteran of the Civil War, in which he served as hospital steward of the One Hundred and Twenty-eighth New York Volunteer Infantry, and formerly a practitioner of Grand Rapids, Mich., died at his home in Los Angeles, Cal., December 6, from tuberculosis, after an illness of ten years, aged 64.

Thomas Benjamin Hunt, M.D. University of Louisville Medical Department, 1864; for nine years a member of the board of education of Warsaw, Ill.; once a member of the State Board of Health; surgeon of the Fifty-fourth Kentucky Mounted Volunteer Infantry, died at his home in Warsaw, November 17, from heart disease, after a short illness, aged 74.

Benjamin Blackford, M.D. Jefferson Medical College, Philadelphia. 1855; surgeon in the Confederate service during the Civil War; in charge of hospitals at Front Royal and Liberty, Va.; an alienist of ability; for 16 years superintendent of the Western State Hospital, Staunton, Va., died at his residence in that institution, December 13, from pneumonia, aged 71.

Evelyn Lyman Bissell, M.D. Medical Institution of Yale College, New Haven, Conn., 1860; surgeon in the Army during the Civil War; a member of the staff of Governor Waller; president of the New Haven board of health, died suddenly at his home in New Haven, from cerebral hemorrhage, December 9, aged 69.

William Henry Harrell, M.D. Medical College of Virginia, Richmond, 1885; for 16 years physician and superintendent of health of Martin County, N. C., and for several years a member of the State Board of Health, died at his home in Williamston, November 27, from pneumonia, after an illness of six days.

Edwin Reynolds, M.D. College of Physicians and Surgeons in the City of New York, 1877; member of the New York State Medical Association, New York State Medical Society, and Medicolegal Society; physician to the Brooklyn Home for Consumptives, died at his home in Brooklyn, December 15, aged 59.

Cassius M. Colegrove, M.D. College of Physicians and Surgeons, Baltimore, 1883; twice president of the village of Canastota, N. Y., died December 9 from injuries received the evening before by being caught between a train from which he had alighted and a freight train, at Canastota, aged 43.

Theodore Deecke, M.D. University of Berlin, Germany, 1857; for 17 years pathologist at the Utica (N. Y.) State Hospital; well known as a pathologist, chemist and medical expert, died at his home in Utica, December 15, after an illness of three years, aged 69.

William P. Caffey, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900, local surgeon of the Denver & Rio Grande Railroad at Castle Gate, Utah, died suddenly from heart disease at his home in that place, December 9.

Lewis Gelston, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905, a member of the medical staff of the Calumet and Hecla Mining Company, Calumet, died in that city from scarlet fever, December 13, aged 21.

Morton Grinnell, M.D. Bellevue Hospital Medical College, New York City, 1881, formerly of New York City, died at his home, Beaver Brook Farm, Milford, Conn., December 10, from pneumonia, after a short illness, aged 50.

Peter Henry Reiche, M.D. University of Maryland School of Medicine, Baltimore, 1869, of Baltimore, was struck by a street car and died, December 9, an hour after the accident, at the City Hospital, Baltimore, aged 68.

William P. Fenlason, M.D. State Certificate (Tennessee), 1899, died at his home in Chattanooga, December 1, from peritonitis due to injuries inflicted by William Waller, for causes unknown, November 18, aged 66.

James Fullerton, M.D. Years of Practice, Illinois, 1878, one of the oldest practitioners of Mason County, Ill., died at his home in Bath, where he had practiced for 52 years, December 6, from senile debility, aged 77.

Thomas Grant, M.D. Manitoba Medical College, Winnipeg, 1896, a member of the American Medical Association, died at his home in North Bend, Neb., December 4, after an illness of more than a year, aged 37.

John J. Dearborn, M.D. University of Vermont Medical Department, Burlington, 1873, died at his home in Salisbury, N. H., December 6, after an invalidism of several years, aged 55.

Nicodemus Theodore Tanski, M.D. Cincinnati, 1882, of Cincinnati, died at the Seton Hospital in that city, December 17, from burns sustained during an attack of syncope, aged 57.

William H. Dowell, M.D. Cincinnati, 1895, died at his home in Green Camp, Ohio, November 30, from pneumonia complicating typhoid fever, after an illness of three weeks, aged 37.

Thomas W. Hunt, M.D. Jefferson Medical College, Philadelphia, 1894, formerly of Lanesboro, Minn., and Bridgeport, Okla., died at his home in Haskell, I. T., September 17, aged 40.

A. Stanley Dolan, M.D. Michigan, 1882, formerly assistant superintendent of the Southern California Hospital for the Insane, died suddenly in his room at Riverside, Cal.

James L. Curl, M.D. Barnes Medical College, St. Louis, 1897, died at his home in St. Louis, November 24, from pneumonia, after an illness of less than three days, aged 29.

Perley I. Aiken, M.D. Jefferson Medical Colege, Philadelphia, 1867, died recently at his home in Honolulu, H. I., after a long and painful illness, and was buried October 28.

Ellwood S. Gloninger, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1887, died at his home in Philadelphia, December 14, aged 50.

L. B. Bond, M.D. Atlanta, 1895; local surgeon to the Baltimore & Ohio Railroad, died at his home in Mt. Clare, W. Va., from typhoid fever, December 6, aged 34.

Herman Joseph Huyett, M.D. Jefferson Medical College, Philadelphia, 1885, died at his home in Rock Island, Ill., from nephritis, December 10, aged 43.

William H. Kroh, M.D. University of Maryland School of Medicine, Baltimore, 1886, died at his home in Los Angeles, Cal., December 11, aged 46.

Charles E. Eskridge, M.D. Louisville (Ky.) Medical College, 1886, died at his home in Winnsboro, Texas, November 29, from heart disease.

Walter L. Allen, M.D. Atlanta, 1900, of Chalk Mountain, Texas, was stabbed during an altercation, July 27, and died four days later.

William O. Collins, M.D. Kentucky School of Medicine, Louisville, 1854, died at his home in Pimento, Ind., November 28, from nephritis.

Isaac D. Newman, M.D. Cincinnati, Ohio, 1885, died at his home in Oakland, Md., December 12, aged 67.

Deaths Abroad.

Sir John Burdon-Sanderson, Bart., M.D. Edinburgh, 1851; F.R.C.P., London, 1863; M.R.C.P., 1855; D.C.L.; D.Sc.; LL.D.; F.R.S.; Honorary Fellow Magdalen College; president Pathological Society; honorary member of Clinical Society; fellow of the Medico-Chirurgical Society; corresponding member of the Academy of Science of Berlin, the Institute of France, Academy of Medicine of Belgium and Royal Scientific Society of Denmark; late regius professor of medicine, University of Oxford; Jordell professor of physiology, University College, London; physician to the Consumptives' Hospital, Brompton; assistant physician and lecturer, Middlesex Hospital; president of the British Medical Association in 1893; bearer of one of the most illustrious names in medicine, died at his home in Oxford, November 23, from broncho-pneumonia, after a pro-

John Burdon-Sanderson, M.D.

longed illness, aged 76. In 1870 Dr. Sanderson resigned his hospital appointments to devote himself to physiology and experimental pathology. His first important contribution was on the best means of resuscitating the apparently drowned. Other investigations were on asphyxia, the pathogenic properties of the stools of cholera patients, the artificial tuberculosis, and the intimate pathology of contagion.

E. Ziegler, M.D., professor of pathology and pathologic anatomy at Freiburg, died November 30, aged 56. He was the publisher and editor of the *Beiträge zur path. Anatomie und zur allgem. Pathologie*, and of the allied *Centralblatt*, and he has contributed a large number of important works to science. The article on "Inflammation" in the "Twentieth Century Practice of Medicine," 1899, was from his pen. He was born at Berne and has served as privat docent or professor at Würzburg, Zurich, Tübingen and Freiburg, removing to the latter place in 1889.

L. Brühl, M.D., one of the first and most prominent members of the German Imperial Health Office, died at Berlin, November 35, aged 70.

R. von Leuthold, M.D., surgeon general of the German army and body physician to the emperor, died at Berlin, December 4, aged 73.

Book Notice

THE PRACTITIONERS' VISITING LIST (Heretofore known as the Medical News Visiting List) for 1906. Lea Brothers & Co., Philadelphia, 1905.

MEDICAL RECORD VISITING LIST or Physicians' Diary for 1906. New Revised Edition. New York: William Wood & Co.

These visiting lists are pocket-sized, wallet-shaped books, bound in flexible leather, with flap, pencil, pocket, calendar, valuable tables and data, and classified blanks for recording various details of practice, such as charges, calls, engagements, addresses, cash account, etc. They are made for various numbers of patients, monthly or weekly, dated or undated, etc. They are excellently arranged for the physician's convenience.

Queries and Minor Notes

SYPHILIS AND REPAIR FRACTURES.

——Dec. 7, 1905.

To the Editor:—I have a case of compound fracture of the tibia near the juncture of the lower and middle thirds. The fibula is also broken. The bones were much splintered and a small piece had to be removed. The patient, a man, had syphilis seven years ago. He took antisyphilitic treatment for a year and a half. He is married, and his wife became infected and had one abortion. She is now troubled with a *syphiloderm*. I have treated both since June with potassium iodid and protoiodid of mercury, ¼ gr. What is the probable effect of syphilis on the uniting of a fracture. What would be the best treatment in this case? X. Y. Z.

ANSWER.—It is generally conceded that syphilis does not interfere with repair of fractured bones. Syphilis, particularly in the large cities, is an exceedingly common disease, yet in the large hospitals it is very rare indeed to find that syphilis has played any part in the cause of fracture, and it is very doubtful if, in itself, it ever interferes with union. In the treatment of the fracture in the above case, therefore, the indications should be met without regard to the syphilitic history. On the other hand, if syphilitic lesions be present they should receive their proper treatment without regard to the presence of the fracture.

PHYSICIANS' CARDS.

Another physician's card comes to our table to add to the collection. The front side contains the following (names being changed):

O. C. TONLAY, A.M., M.D.,
Eclectic Physician.

SPECIALTIES: Skin Diseases.
Nervous Diseases.
Urinary Disorders.
Female Troubles.

WEEKLY BLOCK,
LASINA, NEW OHIO.
TELEPHONE, 187.
German and English spoken.
(SEE OVER.)

The reverse side of the card reads as follows:

Dr. TONLAY has had a practical experience of 33 years as a Physician and Specialist, both in the Allopathic or regular; and in the Eclectic or Botanic Schools of medicine. The Doctor prefers and generally gives the extracts of roots, herbs, barks and flowers of the earth (that is the Eclectic *practice*), *and such* DOES NOT INJURE the most delicate stomach or system. Children do not mind to take my medicines. Dr. Tonlay has taken a special course in study of ALL CHRONIC DISEASES, and particularly upon NERVOUS DISEASES, SKIN DISEASES, AND DISEASES OF KIDNEYS, BLADDER, AND FEMALE TROUBLES. The Doctor *also cures* Rupture, Piles and Goiter by the Hypodermic method without surgery. Having been in the Special practice in New Orleans, La., and St. Louis, Mo., and made Chronic Diseases a Special Study, he claims Superior Skill in the treatment of such troubles.

N. B.—Dr. Tonlay prepares and furnishes his own medicines at his office.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending December 16:

Koerper, C. E., asst.-surgeon, relieved from further temporary duty at the post of Washington Barracks, D. C.

Hanner, John W., asst.-surgeon, granted three months' leave of absence, to take effect on his being relieved from duty in the Philippines Division, with permission to return to the United States via Europe.

Hutton, Paul C., asst.-surgeon, ordered to report in person, December 29, to Lieut.-Col. Geo. H. Torney, deputy surgeon general, president of examining board, at the Army General Hospital, Presidio of San Francisco, Cal., for examination to determine his fitness for advancement.

Ruffner, E. L., asst.-surgeon, advanced to rank of captain from this date (December 15).

Cass, Wm. E., contract surgeon, ordered from Vancouver Barracks, Washington, to Fort Stevens, Ore., for temporary duty.

Adair, Geo. F., contract surgeon, ordered from Fort Wadsworth, N. Y., to Fort Jay, N. Y., for temporary duty.

Branch, Frederick D., contract surgeon, returned from Fort Jay, N. Y., to his proper station, Fort Wood, N. Y.

Slater, Ernest F., contract surgeon, returned to duty at Fort Hancock, N. J., from sick leave of absence.

Chase, Alpha M., contract surgeon, returned to Fort Reno, Okla., from leave of absence.

Marvin, Marion F., contract surgeon, left Fort Robinson, Neb., on leave of absence.

Dickenson, Clarence F., contract surgeon, returned to Fort Logan, Colo., from leave of absence.

Waddell, Ralph W., dental surgeon, left Fort Crook, Neb., on leave of absence.

Navy Changes.

There are no changes in the Medical Corps, U. S. Navy, for the week ending December 16.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending December 13:

Kalloch, P. C., surgeon, *detailed to represent the service* at the meeting of the Maine State Board of Health, Augusta, Me., December 7.

Wasdin, E., surgeon, granted leave of absence for one month from December 15.

Carrington, P. M., surgeon, granted leave of absence for seven days from December 7, under paragraph 189 of the regulations. Granted extension seven days leave of absence from December 14.

Wickes, H. W., P. A. surgeon, granted leave of absence for one month from December 20.

Greene, J. R., P. A. surgeon, granted leave of absence for one month from *December 18*.

Kerr, J. W., P. A. surgeon, relieved from duty at St. John, N. B., and directed to report at Bureau, Washington, D. C.

Corput, G. M., P. A. surgeon, relieved from special temporary duty at New Orleans, La., and directed to rejoin station at New Orleans, La.

McClintic, T. B., P. A. surgeon, granted leave of absence for twenty days from December 13.

Berry, T. D., P. A. surgeon, relieved from duty at New York, N. Y., and from special temporary duty at New Orleans. Authorized to resume leave status.

Long, J. D., P. A. surgeon, granted seven days leave of absence from November 15, under paragraph 191 of the regulations.

Bahrenburg, L. P. H., asst.-surgeon, granted leave of absence for three days from December 11.

Boggess, J. S., asst.-surgeon, granted leave of absence for two days from December 10.

Ebert, H. G., asst.-surgeon, relieved from duty at Fort Stanton, N. M., and on expiration of present leave of absence *directed to* proceed to Seattle, Wash., for exclusive duty in connection with the examination of aliens.

Salmon, T. W., asst.-surgeon, proceed from Ellis Island, N. Y., to Buffalo, N. Y., *for* special temporary duty.

Spratt, R. D., asst.-surgeon, granted seven days' leave of absence from December 6, under paragraph 191 of the regulations.

Frost, W. H., asst.-surgeon, granted two days' leave of absence from November 29, under paragraph 191 of the regulations.

Patterson, A., acting-asst. surgeon, granted leave of absence *for* one month from October 8.

Quigley, F. Leo, acting-asst. surgeon, granted leave of absence *for* seven days from December 9, under paragraph 210 of the regulations.

Richardson, S. W., pharmacist, relieved from duty at Wilmington, N. C., and from special temporary duty *at* New Orleans, La., and *directed* to report to the medical officer in command at New Orleans, La., for duty and assignment to quarters.

McKay, M., pharmacist, *relieved from* duty at Cincinnati, Ohio, and directed to report at Bureau, Washington, D. C., for duty, relieving pharmacist E. M. Holt.

Allen, G. C., pharmacist, relieved from duty at New Orleans, La., and directed to proceed to Fort Townsend. Wash., reporting to the medical officer in command for duty and assignment to quarters.

Allen, G. C., pharmacist, granted leave of absence for two days.

Ryder, L. W., pharmacist, granted leave of absence for fourteen days from December 11.

Troxler, R. F., pharmacist, relieved from duty at Port Townsend, Wash., and directed to proceed to Chicago, Ill., reporting to the medical officer in command for duty and assignment to quarters.

Holt, E. M., pharmacist, relieved from duty in bureau, and directed to proceed to Wilmington, N. C., reporting to the medical officer in command for duty and assignment to quarters.

Neves, George, pharmacist, granted leave of absence for eleven days from December 20.

BOARD CONVENED.

Board convened to meet at Portland, Me., Dec. 11, 1905, for physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon P. C. Kalloch, chairman; Acting Asst.-Surgeon A. F. Stuart, recorder.

CASUALTY.

Surgeon C. T. Peckham died Dec. 9, 1905, at Buffalo, N. Y.

REMOVAL.

Pharmacist H. E. Davis, removed from the service Dec. 13, 1905, effective Nov. 10, 1905.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon general, Public Health and Marine-Hospital Service during the week ended December 9:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 11-Nov. 25, 8 cases.
District of Columbia: Nov. 25-Dec. 2, 1 death.
Florida: Jacksonville, Nov. 25-Dec. 2, 1 case.
Kentucky: Covington, Nov. 25-Dec. 2, 9 cases.
Louisiana: New Orleans, Nov. 25-Dec. 2, 1 case.
Maryland: Baltimore, Nov. 25-Dec. 2, 3 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila: Oct. 7-14, 2 cases.

SMALLPOX—FOREIGN.

Canada: Toronto, Nov. 18-25, 3 cases.
Chile: Iquique, Oct. 28-Nov. 4, 16 deaths.
China: Hongkong, Oct. 7-14, 1 case.
France: Paris, Nov. 4-11, 14 cases, 2 deaths.
Gibraltar: Nov. 12-19, 5 cases.
Great Britain: Leeds, Nov. 11-18, 2 cases.
Madras: Oct. 21-27, 2 cases.
Mexico: City of Mexico, Nov. 4-18, 6 cases, 3 deaths.
Russia: Moscow, Oct. 28-Nov. 4, 6 deaths; St. Petersburg, *Oct.* 21, Nov. 4, 8 cases, 3 deaths.
Turkey: Constantinople, Oct. 29-Nov. 19, 8 deaths.

YELLOW FEVER—UNITED STATES.

Louisiana: New Orleans, July 21-Nov. 25, 3,395 cases, 460 deaths.

YELLOW FEVER—FOREIGN.

District of Honduras: Belize, Nov. 23-30, 1 case, 1 death.
Cuba: Habana, Oct. 16-Dec. 5, 31 cases, 11 deaths.
Ecuador: Guayaquil, Nov. 7-14, 2 deaths.
Honduras: Puerto Cortez, Nov. 19-25, 3 cases, 1 death.
Mexico: Vera Cruz, Nov. 19-25, 1 case, 1 death.
Panama: Nov. 20, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Manila, Sept. 30-Oct. 21, 21 cases, 22 deaths; Province, to Oct. 7, 210 cases, 183 deaths.

CHOLERA—FOREIGN.

India: Madras, Oct. 21-27, 38 deaths.
Straits Settlements: Singapore, Oct. 21-28, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Manila, Sept. 30-Oct. 21, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

Africa: (Portuguese) Chinde, Sept. 29-Oct. 8, 6 deaths.
China: Hongkong, Oct. 7-21, 3 cases, 3 deaths; Yingkow, Oct. 21, 6 cases, 5 deaths.
India: Bombay, Oct. 24-31, 7 deaths; Karachi, Oct. 21-Nov. 5, 20 cases, 17 deaths.
Japan: Kobe, Oct. 14-21, 3 deaths.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon general, Public Health and Marine-Hospital Service, during the week ended December 15:

SMALLPOX—UNITED STATES.

California: Los Angeles, Nov. 18-Dec. 2, 4 cases.
District of Columbia: Washington, Dec. 2-9, 3 cases.
Florida: Jacksonville, Dec. 2-9, 3 cases.
Illinois: Galesburg, Dec. 4-11, 1 case.
Kentucky: Covington, Dec. 2-9, 1 case.
Louisiana: New Orleans, Dec. 2-9, 4 cases.
Maryland: Baltimore, Dec. 2-9, 1 case.
New York: New York, Nov. 25,-Dec. 2, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, Oct. 14-21, 4 cases.
Brazil: Pernambuco, Oct. 14-31, 93 deaths.
Chile: Iquique, Nov. 4-11, 7 cases, 5 deaths.
China: Hongkong, Oct. 25-Nov. 1, 1 case; Shanghai, Nov. 1, present.
France: Paris, Nov. 18-25, 21 cases, 2 deaths.
Great Britain: Liverpool, Nov. 11-18, 1 case.
India: Bombay, Oct. 31-Nov. 7, 1 death; Madras, Oct. 28-Nov. 10, 27 deaths.
Italy: Catania, Nov. 16-30, 3 deaths.
Russia: Moscow, Oct. 7-28, 18 cases, 3 deaths; Odessa, Oct. 21-Nov. 11, 41 cases, 10 deaths; St. Petersburg, Oct. 28-Nov. 4, 6 cases, 1 death.
Spain: Barcelona, Nov. 10-30, 11 deaths.

YELLOW FEVER.

Cuba: Habana, Oct. 16-Dec. 13, 43 cases, 13 deaths; Matanzas Province, Dec. 8-13, 4 cases, 1 death.
Honduras: Puerto Cortez, Nov. 14-21, 1 death.
Mexico: Tehuantepec, Nov. 25-Dec. 2, 1 case.
Panama: Colon, Nov. 21-28, 2 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Oct. 21-28, 4 cases, 3 deaths.

CHOLERA—FOREIGN.

India: Madras, Oct. 28-Nov. 10, 26 deaths.

PLAGUE—FOREIGN.

India: Bombay, Oct. 31-Nov. 7, 14 deaths.
China: Hongkong, Oct. 14-Nov. 1, 5 cases, 5 deaths; Niuchwang, to October, 4 deaths.
Japan: Formosa, Oct. 1-31; 1 case, 1 death; Kobe, Nov. 8-19, 13 cases, 11 deaths; Osaka, Nov. 2-17, 23 cases, 15 deaths.
Strait Settlements, Singapore, Oct. 14-21, 1 death.

Medical Organization

Georgia.

Middle Georgia Medical Association.—The physicians of this section met at Griffin December 8 for the purpose of effecting a reorganization of the association.

Wilkes County Medical Society.—The physicians of Wilkes County met recently at Washington and perfected permanent organization on the standard plan. The new society has on its roll every practicing physician in the county. Dr. Thomas J. Willis was elected president; Dr. John J. Hill, vice-president, and Dr. A. W. Simpson, secretary and treasurer, all of Washington.

Elbert County Medical Society.—The physicians of Elbert County met in Elberton, December 5, and formed a county medical society on the standard plan. The following officers were elected: President, Dr. A. S. J. Stovall, Elberton; vice-president, Dr. Amos C. Smith, Coldwater; secretary and treasurer, Dr. William A. Matthews, Elberton, and censors, Drs. Joseph E. Johnson, L. Pope Eberhardt, and A. B. Matthews, all of Elberton.

Newton and Rockdale County Medical Society.—Under the direction of Dr. Edward C. Davis, Atlanta, councilor for the fifth district, a local medical society has been organized on the standard plan, which includes in its membership the physicians of Newton and Rockdale counties. Dr. E. W. Ragsdale, Starrsville, was elected president, and Dr. W. Darracott Travis, Covington, secretary. The society will meet monthly, alternating between Conyers and Covington.

Kansas.

Greenwood County Medical Society.—The physicians of the county met at Eureka, November 16, and with the assistance of Dr. Oliver J. Furst, Peabody, councilor for the fourth district, perfected the organization of a county medical society on standard lines. Dr. Leslie S. Trusler, Fall River, was elected president; Dr. Jeptha Dillon, Eureka, vice-president, and Dr. William T. Grove, Eureka, secretary and treasurer.

Harper County Medical Society.—On the call of Dr. Oliver J. Furst, Peabody, councilor of the fourth district, a meeting of the physicians in Harper County was held at Harper, November 8, at which a county association was formed on the standard plan. The following officers were elected: Dr. Clarence W. Winbigler, Harper, president; Dr. Charles J. Callender, Anthony, vice-president; Dr. Alpha D. Updegraff, Anthony, secretary and treasurer; Drs. Marcus P. Crisler, Attica; J. Andy Bowles, Bluff City, and B. S. Jordan, Waldron, censors, and Dr. Arthur E. Walker, Anthony, delegate to the state society.

Michigan.

Muskegon-Oceana County Medical Society.—At a meeting held in Muskegon, December 8, the name of the Muskegon Medical Society was changed to the Muskegon-Oceana Medical Society. Dr. John F. Denslow, Muskegon, was elected president; Dr. J. D. Buskirk, Shelby, Oceana County, vice-president; Dr. Vernon A. Chapman, Muskegon, secretary; Dr. Jacob Oosting, Muskegon, treasurer, and Dr. George S. Williams, Muskegon, censor.

Ohio.

Noble County Medical Society.—Dr. Charles H. Higgins, Zanesville, acting for Dr. Edmund C. Brush, Zanesville, councilor for the eighth district, went to Caldwell, November 15, to organize a medical society for Noble County.

Columbus (East Side) Medical Society.—At a meeting held in Columbus, December 6, at which 25 physicians of the East Side were present, it was decided to form an organization.

Dr. George M. Clouse was elected temporary chairman, and Dr. Grace Welch, temporary secretary.

Oregon.

Josephine County Medical Association.—The physicians of Josephine County met recently in Grant's Pass and organized a medical society on the standard plan. At the last meeting the association put itself on record as opposed to the lodge or contract system of the practice of medicine.

South Carolina.

Laurens County Medical Society.—At the annual meeting of this society a reorganization was effected on the standard plan, under the direction of Dr. Orland B. Mayer, Newberry, councilor for the third district. The officers elected were as follows: Dr. John H. Miller, Cross Hill, president; Drs. William H. Gial, Laurens, and S. F. Blakely, Ora, vice-presidents; Dr. A. J. Christopher, Laurens, treasurer; Dr. Rolfe E. Hughes, Laurens, secretary, and Drs. W. D. Ferguson, Laurens; Jesse H. Teague, Laurens, and T. L. W. Bailey, Clinton, censors.

Sixth District Medical Association.—At the annual meeting of the Pee-Dee Medical Society and the society of the Sixth Councilor District, held in Florence, November 15, under the presidency of Dr. Frank H. McLeod, councilor of the district, it was decided to merge the two organizations. The following officers were elected: Dr. James L. Napier, Blenheim, president; Drs. James Evans, Florence; Joseph F. Dusenberry, Conway; Joseph C. Lawson, Darlington, and C. Henslee, Dillon, vice-presidents, and Dr. Bery G. Gregg, Florence, secretary and treasurer. A committee was appointed to revise the constitution and to report at the next meeting.

Tennessee.

Wilson County Medical Society.—The physicians of Wilson County met recently at Lebanon and organized a medical society with the following officers: Dr. G. R. Gwynn, Lebanon, president; Dr. Jerry W. McFarland, Corums, vice-president, and Dr. A. O. Eskew, Partlow, secretary and treasurer.

Sullivan County Medical Society.—The Bristol Medical Society, at its regular meeting, December 4, was formally disbanded and in its stead was formed the Sullivan County Medical Society on the standard plan. Dr. McMinn Pearson was elected president; Dr. M. B. St. John, vice-president, and Dr. Nathan H. Reeve, secretary and treasurer, all of Bristol. The Virginia members of the society will be entitled to retain their membership as privileged members and will enjoy the same privileges as the Tennessee members, with the exception of membership in the State Medical Society of Tennessee.

Texas.

Bowie County Medical Society.—At a meeting of the members of the Bowie County Medical Society and visiting physicians, November 17, to hear Dr. J. N. McCormack, a motion was made and unanimously carried that the secretary of the Bowie County Medical Society express its thanks for the very interesting and instructive addresses of Dr. McCormack, chairman of the Committee on Organization of the American Medical Association, and that a copy of these resolutions be sent to the Secretary of the American Medical Association.

We feel that Dr. McCormack has done us a great deal of good, that new interest has been aroused and that many new members will be the result of his work.

T. F. Kittrell, Secretary.

Society Proceedings

COMING MEETINGS.

American Dermatological Association, New York, Dec. 28-30.
Western Surgical and Gynecological Association, Kan. Mo., Dec. 28-29.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Eighteenth Annual Meeting, held in Louisville, Ky., Dec. 12-14, 1905.

Under the Presidency of Dr. Lewis C. Bosher, Richmond, Va.

Surgical Repair of Injured Nerves.

Dr. J. Shelton Horsley, Richmond, Va., classified the surgical methods of repair as follows: 1. Simple nerve suture, including all cases where the ends of the nerve are brought into direct contact and sutured, even when nerve stretching or resection of the long bone may be necessary. 2. Flap operations, which are usually unsatisfactory. 3. Nerve bridging. By this term is meant those cases in which a foreign substance is used to bridge over the defects between the ends of the divided nerve. This includes not only transplantation of nerve tissue from lower animals, but also *suture à distance.* 4. Nerve implantation or anastomosis. Under this head are included those cases in which the ends of an injured nerve are implanted into a healthy nerve.

He reported a case falling under the last classification. The patient suffered an injury as a result of which the upper part of the median nerve was destroyed for two and a half inches and the musculo-spiral injured in the lower part of the arm, with paralysis of all muscles in the hand and forearm except those supplied by the ulnar. Three months after this the median was implanted laterally into the ulnar. Fourteen months later both flexion and extension returned to a marked degree. At that time the musculo-spiral was cut across and implanted laterally into the median. Ten months after the second operation sensation and motion of the hand and forearm had almost completely returned. In discussing several points connected with the case Dr. Horsley concluded that the extensors must have been supplied through the anterior interosseous of the median, because flexion and extension improved simultaneously, and because extension was not interfered with at the second operation, when the musculo-spiral was completely divided.

DISCUSSION.

Dr. Charles H. Mayo, Rochester, Minn., said one question that interests him more especialy is the difference in the ability of repair of a sensory nerve and a motor nerve; also combined sensory and motor nerves. For instance, about the head, where we have the purely motor and sensory nerves, it is almost impossible to keep a sensory nerve from uniting itself. It will get out and grow for inches and repair itself; but a sensory nerve having peripheral impulses toward the center seems to lack regeneration like a motor nerve in which the impulse comes from the center out. He has taken out the infraorbital, plugged the opening with silver, and has had a case as many as seven years without return of sensation in that area, yet within a few months, after operating again, and removing the silver plug, the sensory nerve which had been lying dormant for this length of time, would get out, hunt up a partner, so to speak, and go to work. Take the motor nerve of the arm, where there are acute sensory and motor nerves, we will get more rapid regeneration because of the peripheral impulses, and as the sensory nerve of the arm is so much in excess over that of the nerve of the leg, we will get earlier repair in the surgery of nerves of the arm than we will in the nerves of the leg.

Foreign Bodies in the Esophagus.

Dr. Stuart McGuire, Richmond, Va., said that the diagnosis of foreign body in the esophagus is based on the history of the case, the external palpation of the neck, the passage of an esophageal bougie, and finally by the use of the x-ray. The character and location of the foreign body being determined, the practical question is how to remove it. If it is round or smooth, efforts should be made to extract it with forceps and probangs, or to make the patient eject it by swallowing masses of partially masticated food and then vomiting. If it be small, it may seem wise to endeavor to push it into the stomach. None of these expedients should be tried when the foreign body is pointed, sharp or angular. Under modern surgical technic an open operation is the safest procedure. There are two means of approach, one by an external esophagotomy, the other by a gastrotomy, and the selection of the method depends on the location of the impaction. If it is opposite the cricoid cartilage, an esophagotomy should be done; if it is below the level of the supraclavicular notch, then gastrotomy should be performed.

As an illustration of the operations of esophagotomy and gastrotomy he reported 2 cases. In one the patient, aged 10, while playing with a glass stopper, put it in her mouth and swallowed it. It lodged in the esophagus opposite the cricoid cartilage and produced complete obstruction. The foreign body was removed by an external esophagotomy.

In the second case, a baby aged seven months, while being dressed, seized an open safety-pin and put it in its mouth. The mother, in her efforts to remove it, pushed it first into the fauces and then into the esophagus. The pin was removed in this case by a gastrotomy.

DISCUSSION.

Dr. J. Wesley Long, Greensboro, N. C., reported the case of a forty-six-day-old infant who had swallowed an open safety-pin; the pin lodged in the esophagus opposite the two cricoid cartilages. A radiograph, however, showed that the point of the pin was below the arch of the aorta. It produced constriction of the esophagus where the left bronchus crosses it, and the pin was removed by an external esophagotomy without shock. He thinks there are some cases in which this operation is preferable to gastrotomy.

Dr. W. S. Goldsmith, Atlanta, Ga., mentioned the case of a patient who swallowed the concave part of a dental plate, which lodged in the esophagus, and was retained for a period of four months. At the end of this time patient was very much emaciated and weak. After locating the foreign body, efforts were made to extract it with forceps, but this could not be done. It then occurred to him to try Bull's method of attaching a series of sponges to a long silk ligature and using an esophageal bougie, passing it out through the mouth and leaving in position the series of sponges. After attaching the bougie, he said it is a simple matter by a few sweeping movements backward and forward to push the foreign body into the stomach and extract it through a gastrotomy opening. The foreign body in this case was of such consistency that the *x*-ray was of no value.

Dr. H. A. Royster, Raleigh, N. C., narrated the case of a child 2 years of age who, two weeks previously to his seeing the case, had swallowed the wheel of a tin toy wagon. The child was able to swallow liquids, but not solids. During this time it subsisted on milk and liquid food. He used a medium-sized shotted semi-elastic bougie for the purpose of an examination; this passed into the esophagus, met with some resistance on its way, after which he was enabled to pass it farther without destruction. After applying a mouth-gag he was enabled to extract the foreign body with an esophageal forceps. The foreign body lay transversely across the esophagus.

Dr. J. Shelton Horsley said that if a foreign body can not be removed by ordinary means, no time should be lost in resorting to early operation. He reported the case of a child who had swallowed a camel from a grab-bag. The child put it into its mouth; it was situated a little lower than the level of the larynx. He tried to extract it by several different methods, but was unsuccessful. He saw the child on the fourth day after it had swallowed the foreign body, did an esophagotomy, and removed it with comparative ease. The esophagus was injured and gangrenous. Septic symptoms developed, and the child died on the fourth day following the removal of the foreign body. He thinks the child's life might have been saved by an earlier operation.

Dr. Charles M. Rosser, Dallas, Texas, reported 2 cases of foreign bodies in the esophagus. In one the foreign body, an ordinary pin, was located by the *x*-ray, but could not be removed by ordinary means. Two-thirds of the pin was buried, but with the aid of the fluoroscope the pin was caught by its head and with forceps extracted. In the other case a child had swallowed a nickel, which was located within two or three inches of the cardiac end of the esophagus. Gastrotomy was performed and the foreign body extracted. The child lived about six or eight hours, then died, apparently without shock.

Dr. Rufus B. Hall, Cincinnati, reported the case of a child of a physician, five months old, who swallowed a safety-pin an inch and a half long. It remained in the esophagus for a time, but at the end of twenty-four or thirty-six hours the symptoms caused by its presence disappeared. The child was able to take the breast and thrived well. An *x*-ray picture was taken, which disclosed an open safety-pin in the pyloric end of the stomach. Parents declined to have an operation done for its removal until unfavorable symptoms developed. Several *x*-ray pictures were subsequently taken, but the child did not develop any symptoms referable to the presence of the safety-pin. When the child was twenty-six months old it passed the pin by the natural route. The child is now 7 years of age.

Dr. W. D. Haggard, Nashville, Tenn., related the case of a child eighteen months old who swallowed a pin, the head of which was as large as a cherry seed. As the child developed cough, the presumption was that the pin had lodged in a bronchus. An *x*-ray picture threw very little light in regard to the presence of the foreign body. The pin appeared to be located in a bronchus with its head down and to the left. The child had little or no pulmonary symptoms to justify an operation. At the end of ten days another *x*-ray picture was taken, but the symptoms were so slight that operation was postponed. Four days later another radiograph was taken, which failed to locate the pin, and shortly after this the child passed the pin by the natural route.

Officers.

The following officers were elected for the ensuing year: President, Dr. George H. Noble, Atlanta, Ga.; vice-presidents, Dr. Stuart McGuire, Richmond, Va., and Dr. E. Denegre Martin, New Orleans; secretary, Dr. W. D. Haggard, Nashville, Tenn. (re-elected); treasurer, Dr. Charles M. Rosser, Dallas, Texas (re-elected).

Baltimore was selected as the place for holding the next annual meeting.

(To be continued.)

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held Oct. 24, 1905.

Dr. H. M. Sherman in the Chair.

Cholecystectomy as an Initial Procedure.

Dr. T. W. Huntington reported the history of a patient who had had repeated attacks of biliary colic, accompanied at times by jaundice, fever and clay-colored stools. At operation after a particularly violent attack, the gall bladder was found to contain 16 large stones and about four ounces of thick, grayish, opaque fluid. No stone could be found in the common duct. The gall bladder was drained, and the drainage tube was removed on the fifth day. The discharge of bile through the fistula continued, however. A few days after the operation the stools became clay-colored and remained so. Seven weeks after the operation the abdomen was again opened. No cause for the common duct obstruction could be found except an enlarged, hard head of the pancreas, probably due to a chronic pancreatitis. A cholecystenterostomy was then performed, using a linen thread to unite the lateral surfaces of the gall bladder to the duodenum, after the method of McGraw, and fortifying with a row of Lembert sutures. At subsequent operations it was necessary to reopen this anastomosis with a knife, after dilating the sinus, and finally to close the sinus itself. Since then the patient's recovery has been rapid and complete. Huntington said that cholecystectomy as a deliberately planned initial procedure is proper (1) in extensive trauma of the viscus where suture is impossible, (2) when there is a long-standing and impermeable stricture of the duct, (3) in gangrene of the gall bladder, and (4) in malignant disease of the gall bladder. It is probably better not to leave in a contracted gall bladder following chronic cystitis in most cases (1) because there may be, as in the present case, an undiagnosed obstruction in the common duct, which could later be relieved by performing a cholecystenterostomy, and (2) because the drainage afforded through the cholecystostomy wound may be of value in relieving an infected biliary system.

DISCUSSION.

Dr. B. MacMonagle stated that there are other possible indications for a primary cholecystectomy. Dr. Clinton Cushing frequently performed this operation, in most cases with satisfactory results. In cholecystitis the gall bladder is infected, and if we can be certain that the common duct is open it might be justifiable to do a cholecystectomy and so remove the main seat of infection. Yet it is hard to exclude stones in the hepatic ducts which may later cause a common duct obstruction and so, as a general rule, it is better to leave the gall bladder in at the operation.

Dr. J. H. Barbat believes that the gall bladder should be removed only when the cystic duct was absolutely occluded and a cholecystostomy could not, therefore, drain the bile ducts.

Dr. T. W. Huntington said that it is difficult to determine whether the closure of the cystic duct is a temporary or a permanent one, and that a stone in the common or hepatic ducts can never be absolutely excluded.

Pseudo-tuberculosis of the Peritoneum.

Dr. C. M. Cooper stated that of the many causes that may give rise to structures resembling true tubercles, the most important so far as the peritoneal cavity is concerned are animal parasites and foreign bodies. Tenia eggs and the hooklets of the echinococcus have both produced in the abdominal cavity a condition that resembles tuberculosis and can be distinguished from it only by finding the causative agents within the small nodules. Cholesterin crystals from a ruptured ovarian cyst and pieces of sponge that had been left in the peritoneal cavity at operation have produced similar conditions. Finally the foreign bodies may be food particles that have reached the peritoneal cavity through a perforated gastric ulcer, as in Hanau's case and the one here reported, that of a middle-aged woman whose illness had begun suddenly six weeks before with pain in the lower abdomen; no fever, vomiting or intestinal obstruction; pulse rapid and feeble; marked aversion to food. The abdomen was somewhat distended, with slight tenderness over its lower portion. Free fluid could be demonstrated within the abdomen. Dullness posteriorly over the ascending colon. Leucocytes, 12,000. At operation a large quantity of brownish fluid was evacuated from the peritoneal cavity and the intestines were seen to be studded with innumerable miliary tubercles. At autopsy a postcolonic collection of pus was found originating from a perforated gastric ulcer. Microscopic examination showed that the peritoneal nodules contained no tubercle bacilli, but did contain small food particles that had evidently escaped from the stomach through the perforated ulcer.

Regular Meeting, held Sept. 26, 1905.

Dr. D. W. Montgomery in the Chair.

Palpable Ulnar Nerves.

Dr. C. M. Cooper showed a patient with a chronic inflammation of the joints, multiple glandular enlargements, and enlargement of the spleen. The ulnar nerves were thickened. Dr. Cooper believes that such thickening is far from uncommon and that it is most apt to occur in patients who have chronic joint affections of the hands. This fact should be borne in mind when enlargement of the peripheral nerves is found in suspected cases of leprosy.

Protection from the X-Ray.

Dr. C. M. Cooper protects himself from the deleterious effects of the *x*-ray by standing in a leaden compartment and making all observations by means of mirrors. One mirror reflects a fluoroscopic image of a known test object and in this manner the penetrating quality of the rays can be estimated. Another mirror, by reflecting the tube itself, indicates the general character of the light. In this manner the operator is not exposed at all to the direct action of the light.

Dr. B. F. Carpenter stated that he knew of an x-ray operator who had no active spermatozoa in his semen as long as he was using this light regularly. Active spermatozoa, however, reappeared after he discontinued its use.

Underlying Conditions in Erythema Multiforme Exudativa.

Dr. P. K. Brown reported two cases of erythema multiforme exudativa which showed lesions in organs other than the skin. The first patient was a child 6½ years old that had had attacks of tonsillitis with endocarditis extending over a period of four years. In December, 1904, the patient had ten days of epigastric pain, and following this some fever and a punctate eruption over the trunk, shoulders and thighs. There was general glandular enlargement, the heart was more irregular than usual, and the murmur was louder. The urine contained albumin, red blood cells, and a few casts. On the third day the patient suffered from pains in the ankle joints. Desquamation began on the fourth day and lasted six weeks. The affected areas desquamated entirely, even the nails taking part in the process. The second patient was the same age. During the first attack in January, 1904, the fever reached 104.2 and lasted three or four days. The first eruption appeared early, covered the whole body and was scarlatiniform in character, except on the shins, where it was more blotchy and irregular. There was general glandular enlargement. Eleven days after the onset, multiple miliary hemorrhages appeared over the body, and these were accompanied by hemorrhages from the mucous membranes and by signs of pericarditis. On certain parts of the body areas of circumscribed edema were visible. Desquamation lasted about two weeks. Blood cultures were negative. There was a marked anemia; hemoglobin, 28 per cent., and red cells, 1,700,000, with a relative increase in the mononuclear leucocytes. The child made a slow but uninterrupted recovery. In the year and a half that have elapsed since that time the patient has had eight or ten similar attacks, some of which have been very light, and only one was accompanied by extensive eruption and desquamation. In the beginning of the attacks undigested food is frequently found in feces, and the breath often has a heavy odor.

DISCUSSION.

Dr. Howard Morrow stated that typical erythema multiforme desquamativa runs a course that is different from that described by the speaker. He was inclined to diagnose the cases reported as desquamative scarlatiniform erythma.

Dr. D. W. Montgomery has seen very few cases of erythema multiforme with severe internal lesions, other than joint pains, that do not yield to the salicylates.

SOUTHERN MEDICAL COLLEGE ASSOCIATION.

Annual Meeting, held at Louisville, Ky., Dec. 11, 1905.

Under the presidencey of Dr. Christopher Tompkins, Richmond, Va.

Ten of the fourteen colleges of the association were represented. More stringent rules applying to the admission of students were adopted.

President Tompkins read an address on "The Advancement in Preliminary Educational Requirements." The suggestions set forth in the address, after considerable discussion, were resolved in a motion which was unanimously passed. The motion provided that from the present time until January, 1908, an applicant for admission to any college of the association must have had two years in a recognized high school or a certificate from an acknowledged preparatory school, besides a grammar school education. After Jan. 1, 1908, there will be required for admission a high school diploma, or a certificate of graduation from a recognized preparatory school, and the courses at the college shall be for four years of seven months each instead of six months, as is the case with some schools at the present time.

Since the last meeting five colleges not in the association have either filed applications for membership or will do so within a short time. Two of the colleges which have filed applications are the Medical Department of Epworth University, Oklahoma City, Okla., and the Medical Department of the Southwestern University, Dallas, Texas. The other three colleges are in Georgia and Maryland.

Officers.

The following officers were elected for the ensuing year: President, Dr. Christopher Tompkins, Richmond, Va. (reelected); vice-president, Dr. T. H. Fraser, *Mobile, Ala.*; secretary and treasurer, Dr. G. C. Savage, Nashville, Tenn. (reelected); executive committee, *Dr. J. S. Kane, Nashville,* Tenn.; Dr. W. B. Rogers, Memphis, Tenn., and Dr. Stuart McGuire, Richmond, Va.

The next meeting of the association will be held at the same time and place (Baltimore) as the Southern Surgical and Gynecological Association.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Oct. 5, 1905.

Dr. R. C. Morris in the Chair.

Hemiterata.

Dr. Charles S. Barnes exhibited a specimen belonging to the class of malformations known as hemiterata. The mother, aged 24, had previously given birth to two healthy children, the oldest 2 years of age. In the second pregnancy there was an excess of amniotic fluid. During the recent pregnancy only apparent abnormalities were increased thirst and undue abdominal enlargement. Labor, delayed because of the excessive distension of the abdomen, was terminated spontaneously after manual rupture of the membranes. The latter was followed by the discharge of about four quarts of amniotic fluid. The child, a male, was apparently well formed, and, for the first twenty-four hours seemed healthy. At the end of this time it began to regurgitate all liquid given by mouth, and later frequently vomited much dark green liquid similar to that seen in intestinal obstruction of the adult. Enemata were ineffective in freeing the bowels. Death by exhaustion occurred at the end of seventy-two hours.

The probable diagnosis of intestinal obstruction was confirmed by the specimen. Two inches of the duodenum, beginning one and one-half inches below the pylorus, consist of a small impervious fibrous cord. Below the latter, for a short distance, the gut is abnormally small but patulous, thence gradually shading into a normally formed gut. The presence of hyramnios raises the interesting question as to whether the abnormality and the hydramnios are related as cause and effect. Though not definitely determined in this case, it seems more than probable that the lesion of the gut in this region may have caused stenosis of the umbilical vein.

A few practical thoughts suggested by this case are: 1. The probable futility of any surgical intervention in this and similar cases, although it would be advisable to try it, if positive diagnosis can be made. 2. The complications of parturition incident to hydramnios. 3. The frequency of the association of hydramnios and fetal abnormalities. 4. The obscurity of the etiology of hydramnios and the desirability of careful search for pathologic lesions as causes. 5. As valuable knowledge is often to be acquired by postmortem study of the fetus, whatever may have been the apparent cause of death, such study should always be made when possible.

Backache in Women and Its Treatment.

Dr. William E. Parke said that backache is a frequent symptom in women coming to gynecologic dispensary service. In a record of 1,000 cases 25 per cent. or more were found to present this symptom. The seat of pain is the lumbar, the sacral or the coccygeal region. The lumbar pains are usually due to some general disorder, while the sacral and coccygeal pains are more frequently due to some disorder of the pelvic viscera, such as lacerations, displacements, inflammations or tumors. The most frequent cause of backache is neurasthenia and this in turn may be due to the pathologic condition of the pelvis. Backward displacements are particularly prone to cause backache, due, perhaps, to impeded circulation. It was present in this condition 194 times and absent only 40 times. Backache was noted in 46 patients without gross pelvic lesions. Many of these doubtless had under-developed or cirrhotic ovaries. Backache is sometimes due to toxemia from intestinal absorption of imperfect metabolism, also to congestion of the menstrual period. Pain in the coccyx is due to inflammation, dislocation or fracture. It is often a pure neurosis. Many diseases of the bowels, muscles, kidneys and nerves which give rise to backache are not referred to in this paper.

The treatment of backache is complex and often unsatisfactory. Medical and surgical measures are employed. Toxic and lumbar backaches are treated with laxatives, diuretics and colon irrigation. Some are given salol, salicylates or iodids. To the congestive type are administered ergot, digitalis, strychnin and bromids. The anemic are given iron and tonics. Temporary relief is afforded by the use of local counter irritation. For neurasthenics the rest cure is advised. Surgical measures have for their object the sewing up of lacerations, the correcting of malpositions and the removal of diseased organs and tumors.

DISCUSSION.

Dr. Charles P. Noble believes that renal trouble seldom causes backache. In cases of movable kidney, as a rule, there is no backache. When present, the pain is due to congestion or to torsion of the ureter. If a loose kidney becomes partly twisted so as to interfere with return circulation, the kidney becomes congested and there is a certain amount of local soreness that may be felt in the back.

Dr. William Krusen emphasized the value of the drinking of large quantities of water in these cases. Frequently a rheumatic diathesis is associated with pelvic disease. He has never seen a case of nephritis with backache, although people think they have kidney trouble when they have backache. Pains may be due to the lithemic diathesis, and a certain proportion of backache is due to traumatism. The fact that women are habitually constipated and that they drink small quantities of water are two factors to be borne in mind in treatment. Hydrotherapy plays an important part in the relief of symptoms.

Miscellany

An Efficient Army Medical Department.—In discussing this Dr. G. Frank Lydston says that the concentration of abundant, up-to-date medical supplies—in the purchase of which boodle should have no part—in centers which present suitable transportation facilities is a *sine qua non.* Surgeons should be given more authority and a freer hand, and should be appointed for their capacity and not for their political pull. Several thousand miles, more or less, of red tape should be eliminated from the medical department and thrown into the ashheap, where it properly belongs.

The Profession of Medicine.—In two respects the medical profession deserves the grateful recognition and regard of all other callings in modern life. It has always insisted that the practice of medicine is a profession and not a trade. Trade is occupation for livelihood; profession is occupation for the service of the world. Trade is occupation for joy of the result; profession is occupation for joy in the process. Trade is occupation where anybody may enter; profession is occupation where only those who are prepared may enter. Trade is occupation taken up temporarily, until something better offers; profession is occupation with which one is identified for life. Trade makes one the rival of every other trader; profession makes one the co-operator with all his colleagues. Trade knows only the ethics of success; profession is bound by lasting ties of sacred honor.—President Faunce of Brown University, Addressing the Rhode Island Medical Society.

Means to Correct the Dispensary Abuse.—Imhofer of Prague discusses, in the *Prag. med. Wochft.* for October 5, the best means to combat the dispensary abuse, which has assumed large proportions there. He suggests as the measures best adapted for local conditions that all applicants to the dispensary should have to pass first through a room where an inspector demands a certificate testifying to the bearer's lack of means or a line from a physician indorsing his application. A card is then given the applicant and he can then proceed to the dispensary proper, or to the clinic or ward. No one is admitted to the dispensary or clinic without presentation of a numbered card of this kind. The inspector is always at liberty to pass an applicant directly into the dispensary or clinic when circumstances demand the avoidance of red tape delay, and an applicant accompanied by his physician should also have free right of way. By some such sifting process the dispensaries and hospitals could be kept free for the poor, while those able to pay for medical attendance would be excluded from them.

An African Poison Test.—Dr. F. C. Wellman describes in the *Journal of Tropical Medicine* the poison test used in Africa to determine the guilt or innocence of a suspected person. He recently saw the test made with fatal consequences. He says:

> The agents which are generally used in this region are obtained from two *Leguminosæ, i. e.,* bark of the Ombambu tree (*Erythrophlœum guinense*) and leaves of a bush called Okalembe (*Jephrosi vogelu*), together with the rootlets of another bush belonging to the *Polygalaceæ* called by the natives Utata (*Securidaca longipedunculata*). All three are powerful poisons. These substances are

dried, powdered with various others, placed in the bottom of a small gourd and carefully covered with the resinous exudation from the Ulemba tree (*Ficus psilopoga*). On top of this is poured an evil-smelling mixture of different harmless solutions. Over the surface of the liquid is sprinkled a light-colored powder. The witch doctor, with many mystic incantations and flourishes, stirs the mess a couple of times with his finger, taking care not to touch the bottom. Then the fortunate party whom it is proposed to acquit drinks. The mixture is again stirred, scratching the resin at the bottom, and liberating the poisonous substances. After a few minutes of ceremonies and rites to gain time for the poison to thoroughly permeate the whole, the draught is once more stirred and the victim (who is always made to drink last) quaffs to his doom. Another method, similar in principle, is to have a skin bag with two compartments, one containing the poisonous powdered substances and the other an innocuous powder of the same color, sprinkling these in turn over the top of an inert decoction.

A SIMPLE CLASSIFICATION OF INSANITY.

THEODORE DILLER, M.D.
PITTSBURG, PA.

"In the interest of a simple classification of scientific terms," Dr. John B. Chapin, in his last annual report as superintendent of the department for the insane of the Pennsylvania Hospital, announces that the statistical tables of this institution have been modified. Turning to these tables one finds only these forms of insanity: Melancholia, mania, dementia and delirium from toxic conditions, paresis, epilepsy and imbecility—the same which were known to Pinel and Esquirol.

Dr. Chapin states that 60 forms of mania and 57 forms of melancholia, and 21 forms of dementia have been formulated; and apparently wearied and disheartened by the various attempted elaborate classifications of the insanities and of the failure of any general agreement between them, he goes back to the simplest of all classifications, that best known in the history of psychiatry, to the general medical profession and to the courts.

While one may readily sympathize with Dr. Chapin's feelings and desires it is not so easy to feel sure that this simple classification really simplifies the subject. Indeed, the question may be fairly raised as to whether it does not make it more hazy. The Gordian knot of the classification of the insanities is not so readily cut.

It would be interesting to know how Dr. Chapin would classify the cases commonly called paranoia or monomania, many of which exhibit neither mania, melancholia or dementia to any conspicuous degree; and how he would similarly dispose of cases known to other alienists as dementia præcox, maniac-depressive insanity, etc.

Certainly such a simple classification can convey but little information to the reader of Dr. Chapin's report. Much could be argued for a partial etiologic classification as compared with it. That a psychosis is of toxic or infectious, of evolutional or involutional origin may generally be ascertained with a considerable degree of accuracy; and a classification which sets forth these facts is helpful to him who peruses it; and hospital reports are intended to be of use to those who read them.

No classification of the enormous group of morbid mental phenomena commonly called insanity has ever been made which has met with general approval. None can be made today. Alienists generally are agreed, however, that a classification on a pathologic basis would, if it were possible, be the ideal classification; and while such a classification is not possible to-day, it is growing less and less impossible. It would seem that alienists should classify "insanities" as fully as is now possible on this basis, leaving to the future its full consummation. To this end it is always helpful to regard every case of insanity as an expression, or more properly, as a partial expression of a physical disease or maldevelopment, applying to it, besides the ordinary tests of psychology, those of the best current methods of clinical medicine.

In the meantime it would appear that a moderately extended classification of the insanities as given by Kraepelin, for instance, is of more practical value than the simple classification to which Dr. Chapin returns in that it allows for a better recognition and a better prognosis and treatment of the various physical diseases which express themselves chiefly or conspicuously by morbid mental phenomena commonly called insanity.

THE NEWSPAPER AND MEDICINE.

H. SHERIDAN BAKETEL, M.D.
JERSEY CITY.

The various news stories on medical topics, which appear in the daily press from time to time, are mines of mirth to those who know. Few articles on medical subjects which appear in the columns of the average newspaper are either truthful, accurate or scientific.

While the perusal of these stories often excites the risibilities unduly, there is a serious side to the matter. Newspapers, which to a very great extent are the popular teachers of the masses, are educating the people in the wrong direction by the dissemination of misstatements. When a part of the press condemns antitoxin because a few persons have died subsequent to its administration, thousands of people are prejudiced against this remedy. Many of these misinformed people would doubtless refuse to allow antitoxin to be used in their families if occasion required and, as a result, innocent lives would be offered up as a sacrifice on the altar of newspaper *inaccuracy*.

The medical profession is to blame for this state of affairs, because, as a whole, the papers do all in their power to present actual facts to their readers.

I know from previous years of experience as an editor in the metropolitan field that many editors take as much care to verify the statements given them as a bank cashier does to verify signatures to checks.

The field of the newspaper man is wide. Although often a college graduate, he can not reasonably be expected to be equally versed in medicine, law, theology, engineering and the other professions, into which subjects his work leads him almost daily. It is not to be wondered at, then, that a great New York paper should solemnly declare that a great surgeon (giving his name, of course), performed a marvelous operation which consisted in tying off the common "catotid" artery, an operation hitherto unknown, etc.

The average newspaper does not desire to make itself the laughing stock of the medical public by the publication of foolish and unscientific statements. The editor is usually actuated by high motives and realizing that the bulk of the people believe what they read, endeavors as far as in him lies, to lead his readers along the paths of truth and right.

He publishes an article on some medical topic, furnished by a young reporter and obtained in good faith, possibly from a drug clerk or hospital orderly. He is ignorant of the fact that its subject matter is rankest nonsense, for none of his medical readers has taken the trouble to so inform him. Thus he goes on publishing misstatements from the same irresponsible source, each time doing more and more to injure the cause of medicine in the eyes of the public.

Had some medical man called up the editor on the telephone and informed him of the blunders in the article the wielder of the pen would have been put on his guard. The young reporter would have heard from "the old man" in no uncertain terms, the drug clerk or hospital orderly as a source of medical misinformation would have been relegated to innocuous desuetude, and when medical subjects were treated in the future a reputable physician would have been consulted. It is in this way that the profession is to blame for the idiotic and inane medical tales which often appear in newspapers.

This growing evil can be remedied by a definite plan of campaign on the part of the trustees of the American Medical Association, the national clearing-house of things medical, which would have as an end the publication of medical truths in all the important papers of the country.

There is hardly an editor in the United States who would not gladly print from time to time accurate articles on medical topics, written in careful newspaper English, free from long and unusual medical terms.

A series of well written articles on the situation in Panama, for example, showing the great progress made in sanitary matters, and the institution of the very latest methods known to hygienic science by Colonel Gorgas and his able assistants and demonstrating how, by careful living along stated lines, the residents of the Canal Zone could obviate disease, would go far toward assuaging the fear of those who have relatives in Panama. If the present campaign against the health conditions along the line of the canal is continued, it will be quite impossible to obtain competent men to go there. The proper kind of publicity would change public opinion.

Again, take the casualities attendant on the barbarous manner in which we celebrate Independence Day. This year, according to newspaper reports, over fifty persons lost their lives by the explosion of powder in some form, while hundreds were maimed, many permanently. A series of articles published throughout the country in May and June, showing the awful results of the past celebrations of the Fourth, and the wide wake left by tetanus and its kindred diseases, would assist in arousing the people against this national slaughter and would conclusively demonstrate that patriotism could be shown in ways other than by killing and maiming the youth of the land.

There is a widespread prejudice among the masses against hospitals and operations. Surgeons are looked on as butchers, seeking whom they may knife. Carefully prepared articles could combat these foolish notions and could bring out the benefit derived from hospitals and operative procedures.

The patent medicine evil is the curse of the nation. Millions of people lay countless millions of dollars in the greedy maw of this ogre. Men and women contract habits from the constant use of patent medicines that forever after hold them in tenacious embrace and prove their ultimate ruin.

In no way could the American Medical Association do a greater service to mankind than by demonstrating to the public, through the daily press, the fallacy of the use of patent, secret nostrums. Of course, some papers, which carry the advertising of these concerns, would not publish articles attacking the business, but a majority of the reputable journals would gladly join in a righteous fight to put the vendors of alcohol and opiates, under high-sounding names, out of business.

Space forbids going further into details concerning the great undeveloped field for medical publicity, other than to say that seasonable articles should be furnished, instructing the people how to prevent the diseases peculiar to the various times of year and how to care for their bodies and their minds.

If such a scheme were put into effect the people would be better off, and would have far more respect for the physician, and the work he is striving to accomplish in preventive medicine and in the alleviation of disease.

The practice of medicine would be raised to a higher plane. Medical men, oftentimes classed by the public as high-grade artisans, would assume the high position to which they are entitled and which their fellow-practitioners in Great Britain already occupy.

To carry out this scheme will take much thought. The most feasible plan, to my mind, is to have the trustees establish a publicity bureau, the chief of which should map out the plan of campaign, oversee the preparation of articles, and communicate with the editors of the large papers concerning their acceptance of special articles. In short, the chief should act in a capacity similar to the managing editor of a metropolitan paper.

If the special stories were put up in the style usually adopted by Sunday papers, carefully edited and suitably illustrated, they would be accepted by practically every decent paper in the country. No two papers in the same city will take the same article, hence it would be necessary to have various separate lists, to which stories would be sent and which would not conflict with the other.

Besides this, it is extremely probable that arrangements could be made with the plate associations which supply specials in stereotyped form to all the weeklies and small dailies in the country, to furnish them with weekly contributions, so that the propagation of medical truth would extend to the very ends of the country, with the result that every reader of a paper from Maine to California and from Dawson City to Key West would profit by reading medical facts, not fancies.

The medical publicity bureau could also inaugurate a method for local, county and state societies to make such medical news public as is deemed necessary, for the correction of evils in their midst and for the squelching of the physician, who calls up the newspaper office every time he attends an accident case, performs an operation or goes out of town.

If the trustees of the Association will take up this matter either along the lines indicated or in a manner which seems best to them, I know that five years from now all the members of the medical profession in the United States will rise up and call the American Medical Association blessed.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Lobar Pneumonia in Children.

Dr. G. A. Sutherland, in the *Clinical Journal* (London), states in the treatment of lobar pneumonia in children that the greater number of cases, if put to bed, with fresh air and suitable diet, will generally recover. These cases, however, although the natural course of the disease can not be shortened, must be carefully observed, in order to relieve any troublesome symptoms which are liable to arise in the course of the disease, and to meet complications which are not unlikely to occur. Among these symptoms is pleuritic pain, which causes the child a great deal of suffering, and in the treatment of this symptom he recommends the application of a turpentine fomentation or a linseed poultice over the painful area for half an hour or until the skin is thoroughly reddened. This may be repeated some hours later, but it should not be kept on the chest continuously, irrespective of the presence of this symptom. He especially emphasizes, therefore, the value of these hot moist applications if used interruptedly.

In the diaphragmatic form of pleurisy two or three leeches may be applied over the affected area in combination with strapping of the affected side. When such treatment fails he recommends as a last resort the use of opium and morphin. In this connection he dwells on the contraindication of opium in pneumonia, because of its toxic effect on the respiratory center, and states that it should not be given except in extreme circumstances. Coughing is another symptom which is very disturbing to the patient, due in part, perhaps, to the irritation of the exudate which is present, or to the presence of a bronchitis. In either case the interrupted use of hot local applications, as described above, is of value.

He speaks also of the position of the patient in bed as being a cause in producing these paroxysms of coughing, and recommends that the position of the child be changed from time to time. If necessary, the use of steam inhalations may be resorted to in irritable conditions of the bronchi. It may be used for from ten to fifteen minutes at a time, and repeated at intervals of every four or five hours. When there is persistent coughing, with or without much secretion, he recommends the tincture of belladonna in doses of from 5 to 10 minims (.30-.65), repeated as the individual case requires. It is especially recommended when the secretion is in excess, as it dulls the sensory branches of the vagus throughout the lungs, and stimulates the respiratory centers. In some cases from 5 to 10 minims (.30-.65) of tinctura opii camphorata will relieve the hacking cough present.

Pyrexia is another condition in the course of pneumonia which sometimes must be combated, but it must be remembered that the height of the temperature is not necessarily an indication of the gravity of the disease, but prolonged high temperature after the seventh day tends rapidly to weaken the patient and must be carefully watched. The author deprecates the use of antipyretic drugs in the reduction of the temperature of pneumonia. In infants the employment of a hot bath, which may be rapidly cooled to 85 F., will frequently cause a drop in the temperature of from one to two degrees, and at the same time will relieve the restlessness of the patient. In older children he recommends sponging in bed with hot or tepid water, and in extreme nervous disturbances the temporary application of cold cloths or the icebag to the head. He also recommends the internal use of liquor ammoniæ acetatis in dram doses (4.00) as an antipyretic. This rise in temperature, however, may not be due to the toxic effect of the pneumococcus alone, but may be caused by gastrointestinal disturbances, and consequently calomel in small doses may relieve the hyperpyrexia, and the restlessness.

In the treatment of insomnia in these cases he recommends cold applications to the head or hot applications to the chest. The use of ammonium bromid in from 5 to 10-grain doses (.30-.65) is recommended as effective and as the least harmful of all the hypnotics. In some cases a dose of brandy, drams 2 to 4 (8.00-15.00) in hot water is recommended as a very efficient hypnotic.

Any signs of cardiac weakness must be carefully watched for, such as dilatation of the left ventricle or failure of the right heart, and at the onset of these signs he recommends the use of alcohol in the form of brandy or wine, strychnia and ether. For an infant one year old in the precritical stage of pneumonia he recommends strychnia in doses of from 1/100 grain to 1/200 grain (.0006-.0003) every four hours. If dilatation of the right ventricle is present, with cynanosis and dyspnea, showing an overaction of the right side of the heart, some depletion of blood is recommended. He therefore recommends the application of three or four leeches over the hepatic region, followed by a hot fomentation to encourage further bleeding. In connection with this treatment he advises further assistance by a two or three-grain dose of calomel, followed by a saline, in addition to the heart stimulants already recommended. Dry cupping is sometimes advised, employed over the base of the lungs posteriorly, as a substitute for the leeches.

He has not seen much benefit from the use of oxygen inhalations.

In some cases dyspnea and rapid breathing arise, which apparently do not depend on the pulmonary or cardiac condition. In such cases the cause is probably the failure of the respiratory center, due to the effects of the toxemia, and in these instances he recommends atropin as a direct respiratory stimulant, combined with strychnia, given in doses of from 1/100 to 1/200 grain (.0006-.0003) hypodermically every four hours for a child 5 years of age.

Laryngismus Stridulus.

Comby, in the *Medical Bulletin*, recommends that in these sudden paroxysms hot compresses be applied to the anterior portion of the neck, and that an emetic be given internally. The child, of course, should be confined to the house, and given hot drinks with antispasmodic remedies. The following combination is recommended in such conditions:

℞.	Tinct. belladonnæ	m. xx	1	30
	Potassi bromidi	gr. xxx	2	
	Syrupi aurantii corticis q. s. ad	℥i	30	

M. Sig.: One teaspoonful every three hours in a little water.

In severe cases the dose of the bromid may be increased. The following combination is sometimes recommended as a substitute for the foregoing:

℞.	Spiritus chloroformi	m. x		65
	Glycerini	ʒi	4	
	Syrupi tolutani	ʒv	20	
	Aquæ dest. q. s. ad	℥ii	60	

M. Sig.: One teaspoonful at a dose, and repeat every half-hour if necessary.

In some cases in which asphyxia may be probable, rhythmic traction of the tongue is recommended previous to intubation or tracheotomy. He recommends as prophylactic treatment of this trouble that any vegetative growths in the nasopharynx should be removed as well as large faucial tonsils, if present.

Mercury in Parasypilitic Conditions.

In the treatment of certain stages of syphilis and in those diseases due to the toxins of this disease, as tabes dorsalis, Dr. Frank Billings recommends mercury given in the usual form, as inunctions, by the application of the ointment to different portions of the body each day, preferably the inner portions of the thighs, the calves of the legs, the sides of the thorax, and the inner portion of the arms. He also recommends as a substitute for this method of introducing mercury into the system, the injections of the bichlorid of mercury deeply into the muscular tissue, about two or three times a week. The dose of the bichlorid recommended is about 1/25 of a grain (.0025). He especially recommends as probably the most suitable preparation of mercury in the treatment of these parasyphilitic conditions the salicylate administered in the following combination:

℞.	Hydrargyri salicylatis	gr. xxiv	1	65
	Liquid paraffin	ʒss	15	

M. Sig.: Five minims injected subcutaneously two or three times a week.

The advantage of this latter form of medication is that it is taken up very gradually by the system, and consequently the effects of mercury are present for a number of weeks or months after these injections have been made, owing to this slow absorption. The size of the dose may be gradually increased, if necessary, to meet the requirements of the case. The iodids are recommended in conjunction with this treatment, and are to be given in gradually increasing doses by the mouth.

The Treatment of Laryngeal Manifestations of Influenza.

E. J. Moure, in an abstract in *Merck's Archives,* states that the laryngeal manifestations of influenza may be described under four different forms—the catarrhal form, the infiltrated edematous form, the ulcerative form, and the myopathic form. As local treatment in these different conditions he recommends an inhalation of the following combination:

℞.	Menthol	gr. x		65
	Balsam peruviani	ʒss	2	
	Thymol	gr. i		06
	Tinct. eucalypti q. s. ad	℥ii	60	

M. Sig.: One teaspoonful floated on a pint of hot water as an inhalation.

In conjunction with this treatment he recommends hot fomentations externally applied to the neck and throat, as especially useful in the painful congestive forms. Scarification, according to the author, may be necessary in the edematous form, when the following combination fails to give the proper relief:

℞.	Cocainæ hydrochlor	gr. ii-iiiss		12-.20
	Sol. adrenalin (1-1,000)	m. xl	2	65
	Glycerini			
	Aq. menth. pip., āā	ʒvi	24	
	Aquæ q. s. ad	℥vi	180	

M. Sig.: To be used as a spray three or four time a day.

Later in the course of the disease, after the infiltration has subsided, he recommends applications of a silver nitrate or zinc chlorid solution, 1 to 100, locally to the affected parts.

Medicolegal

Competency of Witnesses.

The Supreme Court of Georgia says of a witness, in Macon Railway & Light Co. vs. Mason, that, had he been licensed under the laws of that state to practice medicine, he would have been competent to testify as an expert witness on the fact being made to appear that he was a licensed physician. But, generally, nothing more is required to entitle one to give testimony as an expert than that he has been educated in the particular trade or profession. Knowledge gained by consistent and close study of medical works renders one competent to testify as an expert concerning the matters of which he has thus learned. It is not essential that he should be actively engaged in the practice of medicine. Nor is it essential that one who really has a scientific education on the subject should be a graduate of any medical college, or have a license to practice from any medical board. What he knows is what really qualifies him to express an opinion as an expert, and a diploma or license is only important as furnishing satisfactory evidence of his competency as a witness. Accordingly, a person who is neither a physician nor surgeon can express an opinion on a medical question, when the matter inquired about lies within the domain of the profession or calling which the witness pursues. But not being a licensed practitioner, it is necessary to lay the proper foundation showing him to be an expert as to the subjects on which he proposes to express his opinion.

The court also holds that the wife of an injured party is not, because of the marital relation existing between them, and the policy of the law to preserve inviolate the confidential communications between husband and wife, incompetent to testify as to the nature of the injury received by him, and its effect on his physical condition, when there is nothing to indicate that her knowledge on the subject was gained because of any confidence which he reposed in her as his wife. The wife may testify to symptoms which she has observed indicating that her husband suffered from headache, but she should not be permitted to generalize or state any bare conclusion on her observation of others who had headache, she not professing to be an expert.

New Compulsory Vaccination Law.

Chapter 58 of the Acts of West Virginia of 1905 amends section 21 of chapter 150 of the Code of that state by providing that the county court of any county in the state, on petition of 100 voters of the county, shall direct and have enforced on any party or parties compulsory vaccination or quarantine, in case of smallpox epidemic, in any city, town or village of the county or in their said county. Any person refusing to be vaccinated when so directed by the county court, and who can not give satisfactory proof of having been vaccinated previous to that time, or a certificate from a reputable physician showing that a successful vaccination on his or her body is impossible or improper, or sufficient reason be given why it has not been done, shall be placed under quarantine as directed by section 7 of this chapter; provided, further, that when it shall be directed by the county court of any county in this state as herein provided. no child or person residing in a locality in which an epidemic is prevailing shall be admitted to or received into any of the public schools in any city, town, village or the county who can not produce a certificate or satisfactory proof showing a successful vaccination, or a certificate from a reputable physician showing that a successful vaccination on his or her body is impossible or improper, or sufficient reason be given why it has not been done, and the trustees or other officers having charge, management or control of such school shall cause the provisions of this act to be enforced when so directed by the county court. For the purpose of the enforcement of this act the county court may appoint competent physicians in any city, town, village or the county, and fix their compensation, which shall in no case exceed 25 cents for each successful vaccination; and such physicians shall provide themselves with good and reliable vaccine virus with which to vaccinate such persons when directed by the county court. If any physician shall give any person a false certificate of vaccination, as herein provided for, he shall be guilty of a misdemeanor, and on conviction thereof he shall be fined not less than $20 nor more than $100. Any person who shall have smallpox going into another county, within three months of said time, shall be required to produce a certificate showing that he has been properly cleansed and disinfected, which certificate shall state what has been done to accomplish this end, and if said certificate be acceptable to the county health officer of the county to which such person shall go, it shall be deemed sufficient and entitle such person to remain therein, but if not deemed sufficient, such person shall not be permitted to remain therein.

To Prevent the Spread of Communicable Diseases.

Chapter 519 of the Laws of Tennessee of 1905 provides that whenever any case of smallpox, yellow fever, cholera, bubonic plague, typhus fever, diphtheria, membranous croup, scarlet fever, or other communicable diseases exist (except it shall not embrace any venereal disease, such as gonorrhea or syphilis), or is even suspected to exist in any household, it shall be the duty of the head of said household, or any other person in such household possessing knowledge of said facts, to immediately notify the municipal or county health authorities. Furthermore, whenever any physician, surgeon or practitioner of medicine shall know or suspect that any person or persons, whom they have been called to visit, or who has been brought to them for examination (or any other suspicious information received relative thereto), is, or are infected, or even suspected, with any of the aforementioned diseases, he shall, and it shall be his duty to, immediately notify the health authorities of the town or county in which said diseased person or persons are found.

After receiving such notice, it shall be the duty of all municipal or county health authorities to immediately proceed to carry out such rules and regulations as the state board of health may prescribe, having for their object the prevention and restriction of the disease or diseases above mentioned. The house or locality shall be inspected, and the diseased person or persons, as well as any other person or persons exposed to said disease, may be quarantined. And when a case of either of the diseases above named is reported the local board of health or its health officer shall at once cause to be placed in a conspicuous position on the house where it exists a quarantine card having printed on it in large letters the name of the disease within, or to prohibit entrance to or exit from such house without written permission from the health officer, and no person quarantined by a local board of health or its health officer on account of having a contagious disease, or for having been exposed thereto, shall leave such quarantined house or place without the permission of the health officer, and every physician attending a person affected with any of the aforesaid diseases shall use such precautionary measures to prevent the spread of the disease, as may be required by said local board of health. No person shall remove or deface such card, which shall remain in place until after the patient has been removed from the house, or has recovered and is no longer capable of communicating the disease, and the said house and the contents thereof have been properly disinfected by the local board of health and all other sources of danger of communicating the disease are removed. It shall be the duty of every physician in attendance on any person afflicted with any contagious or infectious disease designated in this act to notify the proper health officer when said premises are ready for disinfection, so that the same may be properly disinfected under the directions of said health officer or some other person under his authority.

Municipal and county health officers or municipal and county boards of health may adopt such measures for the general or local vaccination of the inhabitants of their respective jurisdictions as they shall deem proper and necessary, and whenever necessary vaccinate such inhabitants to prevent the introduction or to arrest the progress of smallpox without being authorized or ordered by the state board, and the expenses in whole or in part of such general or local vaccination shall, on their order, be paid out of the city or county funds, as the case may be. Every person who shall refuse to be vaccinated or prevent a person under his or her care and control from being vaccinated on application being made by the said health officer or said board of health or by a physician employed for that purpose, unless in the written opinion of another physician it would not be prudent on account of sickness, shall be fined not more than $5 for each offense, and any physician fraudulently giving a certificate of sickness or of vaccination to prevent vaccination shall be fined not less than $25 nor more than $50.

Other provisions of the act are that whenever a place is quarantined it shall be the duty of the board of health to provide for all persons confined therein food, fuel, and all other necessaries of life, including medicine and nurses whenever necessary. On receipt of notice of existing or suspected disease as above the board of education, superintendent, or school district board shall be notified, and said public school authorities shall not allow any pupil to attend any public school from the house while any inmate of same is sick with smallpox or other communicable disease, or during the period of two weeks after the death, recovery or removal of the sick person. For one believing himself afflicted with a contagious disease to voluntarily go on the highway or enter a public conveyance, or to knowingly aid him to do it, is made a misdemeanor. The state board of health may carry out these provisions whenever a local board neglects or refuses to do it.

6 *Ureteral Catheter and Its Importance in Diagnosis and Treatment of Kidney Lesions. L. W. Bremerman, New York.

1. **Comparative Study of Various Forms of Tuberculosis.**—Ravenel summarizes his paper as follows:

1. The division of mammalian tubercle bacilli into two types, human and bovine, first proposed by Theobald Smith in 1898, has been amply confirmed. These types have cult tinctorial characteristics by which they may The chief point of difference, however, is for greater pathogenic power of the bovine type. Bovine bacilli, however, are met which have low pathogenic power. 2. No other species of mammal has been shown to harbor a variety of tubercle bacillus so constant in its characteristics as to justify its classification as a third type. 3. Other species suffering from tuberculosis derive their infection from man or from cattle. 4. The human tubercle bacillus, as a rule, has a low pathogenic power for cattle, but cultures are not infrequently found which are virulent for the bovine race. 5. The bovine tubercle bacillus has the power of invading the human body and producing the lesions of tuberculosis. 6. We are at present unable to state the exact proportion of cases in which bovine tuberculosis is transmitted to man, but in view of the evidence at hand we must regard the disease in cattle as the source of a certain part of human tuberculosis, and any relaxation in our laws and precautions against bovine tuberculosis would be most unwise.

4. **Cerebral Hereditary Syphilis.**—Butler says that the nervous system is attacked by hereditary syphilis in a considerable proportion of cases, sometimes without cutaneous lesions, the disease remaining latent until puberty or later. The pathologic conditions include cranial osteosclerosis, periosteitis, meningitis, endarteritis, thrombosis, as well as atrophy, sclerosis and softening of the cerebral cortex. The symptoms are recurring convulsions, severe headache, worse at night, and impaired intelligence. Later the epilepsy may disappear. Hemiplegia frequently develops and the patients may become paralytic idiots. Partial motor paralyses, aphasia and disturbances of the special senses may occur. Mental deficiency, occasionally congenital, usually develops at a later period of childhood. Prognosis is unfavorable unless the condition is recognized and treated in its early stages. Congenital syphilis should be vigorously treated with mercury during the prevalence of cutaneous manifestations and, when nervous symptoms develop, potassium iodid, or if this disagrees, iron iodid, should be added.

6. **Ureteral Catheterization.**—From an experience covering several thousand catheterizations, Bremerman feels justified in saying that the procedure is not nearly so difficult as is claimed. When rigid attention is paid to technic and asepsis and the choice of a proper instrument, there need be no fear of dangerous after-complications. He says that he can not entirely agree with some of the authorities when they state that a catheter should never be inserted in the pelvis of the kidney when that organ is involved by any inflammatory process. He has yet to see any untoward conditions arise from catheterizing a pyelonephritic kidney or one affected with a chronic inflammation.

12 Uncertainties and Fallacies in Scientific Medicine. H. B. Hemenway, Evanston, Ill.

7. **Forms of Ocular Tuberculosis.**—Bull says that tuberculosis of the conjunctiva is much more often a primary disease, the result of an ectogenic infection, even in cases in which tuberculosis has already developed elsewhere in the body, than of infection occurring through the blood. Although tuberculous disease of the conjunctiva is not often secondary to tuberculous disease in other parts of the system, it is itself liable to be the starting point of general tuberculosis. An intact normal conjunctiva, however, can never be infected. There must always be a loss of substance, usually a traumatic abrasion. Tuberculosis of the conjunctiva is more often secondary to nasal tuberculosis than primary. The symptomatology and treatment of tuberculosis in the various other anatomic regions of the eye are discussed in detail, and the author draws the following general conclusions: It is doubtful if any case of intraocular tuberculosis is ever a primary disease. In cases of doubt, or of very difficult diagnosis, the injection of tuberculin is an efficient aid to diagnosis. There is a general reaction in at least 85 per cent. of the cases, and some local reaction in about 50 per cent. As a method of treatment, both the old and new tuberculin have proved practically useless in Bull's experience. It is a remedy which needs careful watching. Surgical intervention in intraocular tuberculous conditions of the eye should seldom be done, unless there is considerable pain which tells on the patient's health, because the disease is not primary, and hence excision would remove only one focus.

9. **Fresh Air and Rest in Pulmonary Tuberculosis.**—Pogue says that much harm has been done to consumptives by the indiscriminate prescribing of fresh air, outdoor life, and exercise, without proper instructions and education of the patient, together with a consideration of the extent of the lesions present. The patient in the early stages of the disease who is told to adopt tent life, without being given definite instructions, is very apt to shut himself up tight at night in his tent, and so spends seven or eight hours a day in a closed canvas box. Patients must be kept outdoors all day long in the open air, and practically the same conditions must prevail at night, but they must be made comfortable, and be protected from cold winds, rains, and storms, and, during the summer months, from the direct rays of the sun. The beginning of the outdoor life must be gradual, without abrupt transition from the patient's usual mode of life. Similar fallacies exist in the minds of the laity, and even of the profession also, regarding the value of exercise. The patient who is told to live out of doors and "rough it" usually does not live long to carry out the injunction. Of 62 patients in various stages of the disease, whose histories are known to Pogue, who during the last five years have taken the "roughing it" cure, 43 are dead and only 2 show signs of having their disease arrested. Rest is the element it is important to secure, for usually the patient is only too apt of his own accord to take too much active exercise.

10. **Reduction Treatment.**—Wainwright says that it must always be remembered that obesity can not be successfully treated by the same or similar methods in every case. Corpulent persons, who are otherwise healthy, by careful dieting, plenty of exercise, baths, and other rational means, may reduce their superabundant adipose deposit, or at any rate may prevent an increase. On the other hand, obesity in disease is but a symptom, and the treatment of the obesity alone may, and probably will, have an injurious effect on the patient's general condition. The cause must be treated and the attempts to reduce the flesh must be governed by the disease from which the patient is suffering. Wainwright describes in detail the various measures of diet, exercise, bathing, etc., that are useful, and points out how they may be adapted to the needs of different individuals.

18 *Value of Meat Inspection to the Public Health. D. A. Hughes, E. St. Louis, Ill.
19 Pyelonephritis and Ulcer of the Esophagus Complicating Pregnancy. L. T. LeWald, Manila, P. I.

13. **Avulsion of Trigeminus for Neuralgia.**—La Place has devised a gradual method of avulsion whereby he has succeeded in removing a nerve from the seat of the incision to its ultimate ramifications in the skin itself. A special curved hemostatic forceps is used. The nerve is exposed and lifted from its seat. It is then clamped, but not cut; the forceps, held in the right hand, are turned very gently from left to right, winding both the proximal and remote parts of the nerve on itself. This is done very slowly and deliberately, taking as much as two minutes for one turn of the forceps; otherwise the nerve would break. The nerve gradually yields and winds itself on the forceps, slowly but steadily, and the winding is kept up until the nerve finally breaks. It takes from twelve to twenty minutes to obtain this result, and La Place considers time very essential; otherwise some of the removable filaments might be left behind, and the operation rendered in a measure incomplete. The nerve appears as a tightly wound string about the jaws of the forceps. By placing this in water and shaking carefully the nerve soon becomes limber and disentangled, showing itself in its full anatomic condition much more complete and perfect anatomically than would ever be possible by the most skillful dissection. Four patients have been treated by this method during the last two years, and pain has not returned in any case.

14. **Treatment of Puerperal Infections.**—Holmes summarizes his paper as follows:

1. The battle against puerperal infection is practically won by an adequate system of asepsis and antisepsis. True *autoinfections* very rarely arise, and usually are not of serious portent. 2. It is no more possible to operate aseptically without skilled assistants in obstetrics than in general surgery; *properly to conduct an operative case requires a full quota of assistants.* 3. Puerperal infection is not a specific disease. Diverse types of micro-organisms may be the etiologic factors, and any part of the parturient canal may be the seat of the infection. 4. To treat locally a thermal condition of the puerperium without a clear, pos[illegible] he seat of infection should be characterized as [illegible]. 5. At the present time there is absolutely no [illegible] reaching the offending germs in the uterine submucosa or muscularis. The curette can not discern the locality of the retained remnants of secundines; the finger alone can ascertain this; a placental forceps more easily, more certainly, and with infinitely greater safety, can remove them, *under guidance of the finger.* 6. It is a grave error to neglect digital revision of the uterus *after* any instrumentation for the *purpose* of cleaning the uterine cavity. 7. Nature, by supplying the reaction zone of Bumm, offers the surest safeguard to the woman; [illegible] demand the same rest for the uterus as do [illegible]re. 8. The danger of shreds in the uterus is [illegible] as regards their rôle in infections. 9. Active operative measures endanger the life of the woman doubly or trebly to the extent the expectant plan does. 10. The use of saline purges, administration of ergot, hydrastis, etc., removes much of the danger or necessity for active therapy; in a day or two the danger is often *past*, for, like a baby, the lying-in woman is subject to evanescent febrile elevations.

18. **Value of Meat Inspection.**—Hughes discusses the relation of animal disease to human disease; the methods of meeting these dangers, and what meat inspection as carried on by the government means to the public. Hughes says that at present the only way for people to protect themselves against diseases communicable from animals and to guard themselves against diseased animals sold in the local markets, killed, prepared for the trade without expert government inspection, and foisted on them as wholesome, is to take advantage of the wisdom of the federal law. If they refuse to purchase meats which have not passed the government inspection, their protection is assured. The government has recognized the danger arising from diseased meats; it has devised methods to meet the danger; it assures the people of safety, provided they consume meats guaranteed to be free from disease.

28 *Syphilitic Fever. J. A. McKenna, Philadelphia.
29 Relapsing Fever. Koch, Hongkong, China.

20. **Etiology of Syphilis.**—Flexner reviews the subject generally, considering more particularly the causal relation of the pallida to syphilis.

22. **Thyrotomy versus Laryngectomy.**—Jackson calls attention to the frequently malign nature of chronic hoarseness, and urges the necessity for early diagnosis while the case is still operable by thyrotomy, whereby not only the life, but the voice, the comfort, the happiness and the usefulness of the patient may be saved. If the diagnosis be made late, as it usually is, total laryngectomy offers the only hope of prolonging life. Speaking of the endo-laryngeal operation, he says that he considers his years of training to acquire endolaryngeal skill an utter waste of time so far as the surgery of malignant disease is concerned. It is ten times worse than letting the growth alone, for while failing to extirpate radically it induces local spread and metastatic deposit. He concludes as follows: 1. The patient with cancer of the larynx must have his disease discovered early, else a cure is well nigh hopeless. 2. If discovered early the comparatively slight operation of thyrotomy will cure. 3. If discovered late, total or partial laryngectomy will probably prolong life for a variable period, but recurrence is fairly certain and the short extension of existence lacks many pleasures and comforts. 4. The early curable stages of laryngeal cancer are characterized by nothing but hoarseness, which may disappear and recur. Cough, odor, pain, odynphagia, glandular involvement, external swelling, emaciation, cachexia, etc., are present only after the curable stage is passed. 5. The curable case may come in "to get something for a cold that he can not shake off," without any idea of a serious condition, and throws the physician off his guard.

24. **Simple Device for Ophthalmoscopic Work.**—In order to get a satisfactory light under the varying conditions which confront any one trying to do eyework outside of a well-equipped office, Riggs envelopes an ordinary 16-candle power frosted electric bulb in a thin sheet of lead. With a jackknife and a pair of pincers the sheet is cut and molded to the general shape of the bulb. In this way practically all light is shut out except that which passes through a spherical window about one inch in diameter, cut into the shield after it is applied. Thus with a little ingenuity, and in a few moments, any one who cares to try it, and has electrical attachments at hand, can construct for himself a portable and satisfactory light, which may be suspended from any convenient point and allowed to take a position just behind and to the outside of the ear on the side under examination. The light obtained is soft and equally distributed, and one is scarcely bothered at all by the corneal reflex. The background of the eye is distinctly though softly illuminated, and besides giving the observer an almost normal image, it inflicts on the patient a minimum amount of discomfort. Riggs says that with this arrangement one can easily observe the fundus without the use of a mydriatic, nor is it necessary to have a perfectly dark room. It also gives an equally good view in work about the ear, nose or throat.

25. **Electricity in Urinary Incontinence.**—Rockwell cites the case of a girl aged 13 who was treated successfully by the isolated induction shock. The positive electrode was applied to the sacral region, and the negative, consisting of an olive-shaped electrode, was introduced through the urethra to the sphincter muscle. The isolated induction shock was then administered at the rate of one in five seconds, or about twelve shocks a minute. The applications were repeated every other day for a time, and then less frequently. The character of the treatment so far as concerned rapidity of interruption was approximately adhered to throughout the whole course. The patient finally recovered, but the progress toward complete recovery was neither rapid nor constant, some thirty-five applications having been administered through a period of five months. During this period she had alternations of comparative freedom from attacks and their recurrence with ordinary frequency, but the progress was steadily upward.

26. Treatment of Chronic Urethritis.—Trendwith emphasizes the necessity of making an exact diagnosis and of determining the exact status of the case. As a routine measure he advocates the examination of the prostate and seminal vesicles. The treatment should be general as well as local. The local treatment should be governed entirely by the reaction produced by the remedies employed. The urine should be examined at each visit, and no physician should be satisfied to call a patient cured simply because the discharge has ceased. A cure may be said to have been effected when there is no longer any discharge and when the urine is free from pus, shreds or threads, and remains so. Local treatment should be discontinued, but not so the general treatment. The author's method of treatment is described in full.

27. Improved Head Holder for Removal of Brain.—The apparatus devised by Stroud consists of a base made of steel tubing, to which is joined a movable upright that can be fixed rigidly at right angles to the base. The upright bears movable jaws to grasp the head on each side and spurs to enter the auditory meatuses; also an adjustable support for the chin. The head is held firmly and both of the operator's hands are free. The apparatus is finished in white enamel and nickel; when not in use it folds flat, so that it occupies little room. The subject lies on the belly, the head being supported and firmly held by the adjustable clamps at the sides and chin. The base of the cranium is horizontal, and serves as a shallow tray in which the brain is supported while the cranial nerves, arteries, spinal cord and membranes are being severed. Thus it is possible to secure a perfect anatomic specimen. The cranium is opened by making a circular cut with the saw about one-half inch above the orbital prominence and the external occipital protuberance. The calvarium is removed either entire or in two pieces by making a second sagittal cut, about one-half inch from the median line over the top of the head to meet the horizontal line. Adhesions between the calvarium and dura are separated by means of a long flexible spatula. The following liquid has been employed by Stroud for a number of years to preserve brains, and has given excellent results:

℞.	Sodium acetate	℥xiv	400
	Sodium chlorid	℥xiiss	350
	Formaldehyd 40 per cent............	fl. ℥ii	60
	Alcohol 95 per cent..............	fl. ℥xlvii	1,400
	Water	fl. ℥liv	1,600

The sodium acetate and sodium chlorid are dissolved in fifty-four ounces of water by aid of heat. The solution is filtered and cooled and forty-seven ounces of 95 per cent. alcohol and two ounces of formaldehyd are added. This quantity is sufficient for one human brain. If the specimen is much stained by hemorrhage, the blood may be removed by soaking for a few hours in a solution of salt and water. Ordinarily this treatment will not be required. Brains should remain in the solution for from ten to fifteen days, but a longer period is not harmful. Then they may be put into 75 per cent. alcohol, which should be changed once or twice. They may remain indefinitely in 75 per cent. alcohol, or preferably be put into 82 per cent. alcohol. The advantages claimed for this solution are: 1. The mixture is simple and may be prepared at a moderate cost, about 14 cents per liter, alcohol free of tax. 2. It has about the same specific gravity as that of the brain, which should float without support midway between the top of the liquid and the bottom of the jar. Rarely a brain may sink to the bottom; in this case more salt is added. If it floats on the top, 50 per cent. alcohol is added until it sinks below the surface. 3. The specimens have a more natural appearance than when some other preservatives are employed. 4. There is no distortion. 5. It appears to give good results for brains which are very soft from decomposition. In these cases the pia can not be easily removed. 6. Plexuses and membranous parietes are preserved. 7. The alba and cinerea are visibly differentiated. 8. Brains are moderately flexible, so that fissures may be explored. 9. Tissue hardened in it may be used for histologic study.

28. Syphilitic Fever.—According to McKenna, the varied symptoms which cloud the diagnosis of syphilitic fever and make its recognition difficult, may be ascribed to so many of the febrile diseases that the failure of the physician at once to classify properly a case in which syphilis is the cause, is both natural and pardonable. McKenna says that if evidences of syphilis were more often looked for in continued fevers of a doubtful character, or, as a chance, specific treatment given the patient, doubtful diagnosis would frequently be speedily made definite and the health of the patient and the reputation of the physician advanced in a gratifying manner.

30. Fractures of Lower End of Radius.—Lothrop summarizes his views as follows:

1. Fractures at the lower end of the radius are very common lesions. As a result of neglect on the part of the patient, or oversight or otherwise on the part of the physicians, the final result is frequently unsatisfactory, either from the standpoint of function, or appearance, or both. 2. Appropriate treatment applied early should give as good a result as could be obtained in any given case; therefore, subsequent operation is not indicated. 3. In cases in which the final result [illegible] surgical interference of some sort is usually [illegible] the first three weeks whatever union has tak[illegible] e broken up by manipulation under an anesthetic and suitable apparatus should then be applied as for a recent fracture. 5. After the third or fourth week the best results are obtained by means of an osteotomy in the line of fracture, followed by treatment appropriate for a recent fracture. 6. In fractures which have existed for from two to six months osteotomy should always improve the position and frequently improves the function, although special consideration should be given each case. 7. After the expiration of six months it is more difficult to correct the deformity. The backward and upward displacement of the lower fragment can always be overcome, but the correction of the lateral displacement is more difficult and usually requires an osteotomy of the ulna. The function is rarely improved at this time. Hence, interference should be limited to selected cases.

32. Conservatism in Treatment of Ununited Fractures.—Monks cites a case for the purpose of showing that union is possible in ununited fractures of the shafts of the bones of the lower leg after very long periods of time. In this case union took place about two years after resection of the ends of the fragments, and about three years after the original injury. Even in cases in which the bones are considerably shortened (it was estimated that the shortening in this case was about two inches), the muscles will contract sufficiently to enable the patient to balance himself on the injured leg.

44. **New Method of Arthrotomy.**—The steps of Andrews' operation are as follows: 1. An incision is made from the clavicle downward across the front of the shoulder into the axilla. The cut is large, 50 per cent. longer than by the older methods. 2. The pectoralis major is cut near its insertion, leaving about 1 cm. attached to the bone. This muscle, being cut transversely, is laid over with the skin flap, thus exposing the axillary vein and the brachial plexus. The pectoralis minor is not cut, unless the head of the humerus and the vessels have been forced under it. 3. Careful examination of the vessels, if they cross the tuberosity or head of the humerus, is now made. The artery can not be seen readily, except by drawing aside the vein. On account of this deep position, it is more often involved in the adhesions, and has been the vessel usually torn. Great care and plenty of time are needed to separate these vessels when they or their large branches—e. g., subscapular or circumflex—are found adherent. No efforts at reduction should be made until the vessels and large nerve trunks are isolated and pulled aside. It must be borne in mind that some of the reported injuries of the vessels are due to projecting fragments or spicula on the humerus. 4. The forearm should now be flexed on the arm as a lever, and an assistant should rotate, and make traction, when the fibers of the adhesions will be seen and heard to tear gradually, so that the range of motion increases. Andrews says that this part of the work should be intrusted to some one of experience and judgment in joint work, as everything depends on using a sufficient, but not a dangerous amount of force. The operator, while this is going on, should clear the socket of any granulations and cut and nick such bands as refuse to yield after hard stretching. He should search for the lumen of the shrunken capsule. The head and glenoid cavity soon approach each other, the operator tilting the scapula toward the head of the humerus, and giving directions simultaneously as to reflexing, extending, abducting and rotating the limb, as he sees fit. The operator should not attempt this part himself, ordinarily. At the last moment the head is apt to take a subglenoid position and refuse to ride over the lower rim of the socket. Before cutting the ligaments or sclerosed muscles more widely, as one is tempted to do, if a blunt hook or retractor be made to pull the upper end of the humerus straight away from the body, the head can sometimes be dragged over the lip of the socket by a smart pull at the critical turn of the manipulation. Once in place, the bone can usually be held, although the capsular ligament is far from being intact; sometimes, in fact, has lost its identity in a mass of fibrous tissue. The arm should now be kept against the body until bandages are on. 5. The pectoralis major, and, if cut, the minor, should now be reunited by the Harris tendon suture method, and the skin closed with separate suture. Drainage should rarely be dispensed with. Andrews' operation is invariably a bloody one, if the dislocation is of long standing and the adhesions are firm. Good drainage for a few days prevents infection, which can easily take place with large joint surfaces bathed in wound secretion. Andrews concludes as follows: 1. It must be considered established that great force is never justifiable in old shoulder dislocations. 2. Few cases can be left unreduced on account of pain and pressure symptoms on the brachial plexus. 3. Resection is more satisfactory, but not ideal or wholly safe. 4. Arthrotomy by the old incisions is tedious, and never has been widely practiced, but has shown good results. 5. Arthrotomy by Andrews' method is simplified and made quicker, as well as safer. It would possibly be as safe as resection, and much more ideal in results.

45. **Artificial Dilatation of Cervix Uteri.**—Knapp reviews the indications and the methods employed for artificial dilatation of the cervix uteri without offering anything new.

51. **New Operation for Correcting Retrodisplacements of Uterus.**—To secure all the advantages of the Alexander operation, and yet to have an operation which could be combined with the median incision and still avoid the creation of pathologic conditions, Barrett advocates the following procedure: The abdomen is opened in the median line, through an incision from one and one-half to two inches in length. Intra-abdominal complications are dealt with. The round ligaments are picked up with the author's rubber-jaw forceps, and a control ligature is thrown around each ligament, from two and one-fourth to two and one-half inches from the angle of the uterus. If they are exceedingly well developed, a longitudinal slit is made over the ligament and the peritoneum not included. The edge of the aponeurosis over the rectus muscle is now grasped close to the lower angle of the wound, and curved ligature forceps are carried between the aponeurosis and the rectus muscle, outward to the natural exit of the round ligament, the internal ring, where the forceps is guided into the abdomen by sight or by means of one or two fingers through the abdominal incision as a guide. It is not difficult to have the forceps follow the round ligament subperitoneally to the control ligature. The forceps now grasp the control ligature, and it is withdrawn, and along with it is a loop of round ligament. Each loop of round ligament, while being held by the control ligature, is sewed to the under side of the aponeurosis with catgut, about one inch from the median line, and should the loops prove long enough, as they frequently do, they are sutured together in the median line over the recti muscles. The round ligament runs from the uterus to its normal exit, the internal ring, then under the aponeurosis to the lower angle of the abdominal incision, close to the symphysis pubis, to the under side of which aponeurosis it is attached one inch from the incision. The ligament now retraces its steps to the internal ring, from whence it follows its normal course to the labium majus. This leaves no opening for strangulation of the bowel. The ligament leaves the abdomen at its normal place and utilizes the normal structures as a pulley for the round ligament. The uterus is now held by the very best part of the round ligament, a ligament which has capacity for evolution during pregnancy and involution thereafter. The nature of the operation has led the author to term it "intramural transplantation of the round ligaments." This operation has seemed to present the following advantages: 1. It may be employed where there are intra-abdominal complications of any extent, and through the best possible opening for dealing with those complications. It is easy of execution through even a very small opening. 3. It creates the least possible pathology, forming no new ligament. 4. It utilizes the very best part of the round ligament, acting through the internal ring. 5. It has shown the highest efficiency in holding the uterus forward and yet allowing the normal range of movement.

52. **New Operation for Phimosis.**—Lespinasse has devised what he calls the bloodless cuff operation. Although the operation is not applicable in inflammatory cases, nor is it applicable to infants, it is still said to possess points of advantage and distinction. There is practically no hemorrhage; the postoperative edema is absent or very slight; it does not entail detention from business, and it removes the wound a goodly distance from the urinary meatus, hence it is easy to keep it uncontaminated. The cosmetic result is excellent. The frenulum is first cut from the glans down until the perifrenular pockets are obliterated and the frenular region is smooth. If the frenulum is thick, it is best to leave a little flap from one of its sides to cover in the defect. If short and thick the area is left to granulate, which it does very quickly. The next incision is circularly around the shaft of the penis through the skin only and paralleling the sulcus about ½ cm. behind it, being careful to avoid the veins. Next a similar incision is made at an equal distance behind the sulcus and paralleling it through the mucous membrane only, being careful to avoid the veins here also. When the prepuce can not be retracted the skin incision is made and the dissection is started from it as usual. As the mucocutaneous junction is approached the stenosis is relieved and the prepuce can be retracted. The mucous membrane incision is made and continued as ordinarily. The distal edge of the skin incision is caught and dissected off from the fascia, keeping very close to the skin. It is a matter of no consequence if the skin is nicked, while it is

a serious slip if some of the large veins are nipped. The incision is continued to the mucous-cutaneous junction, then the prepuce is retracted and the dissection started anew on the proximal side of the mucous membrane incision, continuing it till it meets the skin incision. The cuff is slipped off the penis and the cutting part of the operation is completed. If the incisions have been properly placed the two cut edges lie accurately fitted to each other and only need to be sutured. To obviate the tendency of the skin to in-roll, Lespinasse advises placing, first, a continuous suture of absorbable material very close to the edge of the incision; second, an interrupted suture of a stiff, non-yielding material, as silkworm gut, placed far back and ends cut long, thus preventing in-rolling by its stiffness and bridging action; or the elevation of the cut edges like the sides of a tent with a suture clamp to hold them in place. A gauze strip about 9 inches long and 1 cm. wide is wrapped very tightly around the penis, covering the wound. What is desired is pressure to the limit oozing and edema. Over the gauze a narrow and snugly fitting bandage is applied. A large bandage is passed around the waist, and from this a T is dropped down to the penis, having this T 4 inches wide at least, and long enough to reach the scrotum. The penis is placed upright against the abdomen and the T is so regulated that it will retain it there. The glans is covered with a piece of gauze heavily smeared with zinc salve or sterile vaselin, the patient being instructed to replace it after each urination. If the glans swells and pains because of the constriction of the dressing, gentle, firm pressure with the thumb and index finger will reduce it and quiet the discomfort. The dressing must be changed in twenty-four, or at the most thirty, hours. The gauze strip must be removed or markedly loosened by that time, its function of limiting edema and serious extravasation having been fulfilled and further action would be harmful, possibly causing gangrene.

53. **Prostatotomy versus Prostatectomy.**—Unless the bladder, ureters, kidneys are water-logged, as it were, with toxic material, Barnett considers prostatectomy practically devoid of danger; but when there is marked disability, albuminuria, casts, etc., he considers prostatotomy indicated. After drainage has relieved the body of its poison, a prostatectomy can be done at a second sitting, if necessary, with less danger.

54. **Asepsis in General Surgery.**—After a careful study of the different methods of sterilization of hands and the wound area, Means has come to the conclusion that a strict aseptic method is the only one on which the surgeon can depend primarily, followed by the use of chemical agents for their inhibitory action. This method consists in thoroughly washing the hands in pure soap and sterile water, treating the nails and rinsing the surface with clean water to remove the soap; then the hands and arms may be submerged in a 1 to 3,000 bichlorid solution or a 1 per cent. carbolic acid solution. The management of the wound area is along the same lines.

58. **New Hemorrhoidal Clamp.**—The clamp devised by Hamilton does away with the tissue which has been clamped and in which sloughing would follow if it was allowed to remain. This clamp consists of slotted blades, 2 inches in length, the blades being at right angle to the handle. The under surfaces of the blades are grooved to a depth even with the upper surface of the slots. This groove is wide enough to exert no pressure of consequence on the base of the tumor. The under surfaces of the blades are rounded to facilitate suturing, and the heel of the instrument is properly smoothed off. The upper portion of the clamp blades above the slots and the groove come together with serrated edges, which give as firm a grasp of the tissues as is needed. The use of the instrument is simple. The usual preliminaries of stretching the sphincters and cleansing the field are attended to; the tumors are brought down to suit the operator's convenience; the clamp is applied parallel to the long axis of the gut and with the heel of the instrument toward the center of the anal orifice; proper pressure is made by the clamp blades; sutures are then passed under the instrument, its rounded under surface felicitating this procedure; a blunt-pointed bistoury or thin scalpel is inserted in the slots and the hemorrhoidal area separated thereby. The clamp with the hemorrhoid is removed and the sutures tied. Either continuous or interrupted sutures are used, usually of catgut of a size suited to the exigencies of a given case. The idea in this instrument is that the lips of the cut surface have not been injured by the crushing of the clamp blades, consequently if proper sterilization of the field has been carried out primary union may be expected here as in any part of the body; and if primary union fails to result, there is no sloughing mass which has to be cared for and healing is advanced by just so much.

7 *A Hitherto Undescribed Change in the Urine of Patients Suffering from Nephritis. M. A. Ruffer and G. Calvocoressi.

3. **Plastic Operation for Stricture of Common Bile Duct.**—Moynihan reports a case of gallstones in which the common duct was obstructed by a cicatricial stricture which was evidently the result of an old ulcer. After the stones had been removed from the duct the second portion of the duodenum was mobilized after the manner of Kocher. The stricture, which had been freely divided by a vertical incision, was then abolished by the approximation of the edges of this incision in a transverse direction. A through-and-through suture of catgut was used, threaded on an intestinal needle. The transverse wound was not completely closed, sufficient room being left for the introduction of two rubber tubes, one of which

passed upward into the dilated common duct and the other downward toward the ampulla. Each tube was fixed with a single catgut stitch. The tubes were removed on the eleventh day. For four weeks all the bile passed through the wound. Some pancreatic juice also escaped in this way, as was shown by the digestion of the skin around the wound. In the fifth week bile began to pass into the intestine, and in the ninth week the wound was entirely closed. The patient was sitting up in bed from the first, and was allowed to get up in the third week.

5. **Portal Pyemia and Pylephlebitis.**—Brown has collected 48 cases, in 7 of which (14.6 per cent.) the occlusion was the result of sepsis. He found that in some cases of portal pyemia obstruction symptoms occur, but in the majority of cases they do not. Their absence, however, can not be regarded as excluding pylephlebitis. Their presence is usually the result of a firmly adherent clot in the portal vein or its annexes, rather than of the soft, disintegrating, purulent thrombus. The commonest place for the adherent clot to form is at the junction of the superior mesenteric and splenic veins. He concludes as follows:

1. A collection of pus within the portal zone is the principal cause of portal pyemia. Ulceration of the alimentary tract is only important as being a frequent precursor of such a collection.
2. Signs of portal obstruction are the exception in suppurative pylephlebitis.
3. There are no signs by which we can distinguish with certainty cases of portal pyemia with suppurative pylephlebitis from those in which the vein is not involved.
4. In "adhesive pylephlebitis" the essential feature is the occlusion of the vein, and this may be produced by a variety of causes, among which sepsis is not an infrequent one.
5. Therefore, if our terminology is to accord with pathological conditions so far as they can be determined during life, we ought to speak of two conditions, portal pyemia and portal occlusion, remembering that we may meet with cases of portal pyemia with occlusion.

7. **The Urine of Nephritics.**—The result obtained by Ruffer and Calvocoressi, in experiments made to ascertain whether pathologic urines contain more or less lysogen than normal urines, shows that the physiologic action of the urine of cases of chronic and diphtherial nephritis, in the large majority of cases, is very different from the action of the same quantity of urine of healthy human beings.

12 *Ethyl Chlorid as an Anesthetic for Infants. F. Murray.
13 Two Cases of Spasm with Hypertrophy of the Pylorus in Infants Cured with Opium. N. Neild.

8. **Treatment of Attack in Spasmodic Asthma.**—Morison describes his treatment of the attack in spasmodic asthma as carried out frequently and always with success. The principle of the treatment is to aid the patient to empty the chest of air. With one hand on the back and the other on the front of the chest, Morison empties it at the end of each inspiration. After several maneuvers of this kind relief is given. Even in old people with stiffened chests he has found compression by one hand over the thorax and the other over the epigastrium, the lower ribs, or preferably over the right hypochondrio-epigastric region, give relief from the thoracic anxiety attending the fixation of the chest, which is chiefly inspiratory. It is unnecessary to give any drugs.

9. **Traumatism as Cause of Appendicitis.**—Southam cites 4 cases illustrating the fact that a direct injury may excite an attack of acute appendicitis when a concretion is present.

12. **Ethyl Chlorid Anesthesia for Infants.**—Murray regards ethyl chlorid as one of the best means of producing anesthesia of from five to fifteen minutes' duration in infants and older children. She has administered ethyl chlorid to 150 infants under a year old. The youngest patients were five and fourteen days old respectively, and a large proportion of them were from five to seven weeks old. Many of them had not undergone any preparation at all, and the only precaution taken with regard to the others had been to withhold food for some hours that morning. The use of ethyl chlorid in prolonged operations is not recommended, partly owing to the waste of the drug by evaporation, and partly because it has no special advantage over chloroform and the A. C. E. mixture when a narcosis of from twenty to forty minutes is required. Murray has found ethyl chlorid very suitable for tenotomy, circumcision, empyema, and the removal of adenoids, cysts, polypi, dermoids and nevi. Murray says that the simplest form of inhaler is the best to use; a useful one consists of an ordinary shaft on to which the face-piece and bag fit; the free end is closed by a stopper attached by means of a fine chain and the anesthetic is sprayed through this opening. To the end of the shaft which enters the bag two curved wires are fitted, so adjusted as to make a little cage in which a small sponge is placed. When ethyl chlorid is sprayed into a bag of the usual size, part of it vaporizes and the other part tends to fall to the bottom and to vaporize as the patient breathes in and out. A young infant does not make a sufficient respiratory effort to produce the necessary amount of vaporization and for this reason induction is often unduly delayed and the anesthesia is not smoothly maintained. The sponge inside the bag intercepts the anesthetic and by holding it nearer to the child obviates these defects, making it possible for the patient to inhale it more rapidly and without effort. The same result is obtained if a bag of about half the usual size is employed, but it is not always convenient to change the bag between the cases. A celluloid face-piece is generally preferable since it not only permits the anesthetist to observe the patient more readily, but also resists the action of the vapor better than rubber. For infants of a few days or a few weeks old Murray commences by spraying 3 c.c. into the inhaler; for those of six months and upward she gives 5 c.c. at once. The mask is then approached to the face but not pressed against it, so that the baby has several breaths of air and vapor mixed; it is then more closely applied so as to exclude all air except that which is already in the bag, and in a few seconds the child becomes unconscious. When one is sure that the anesthesia is deep, and the surgeon has made his incision or begun the operation, the mask should be removed from the face and a few breaths of air should be given. If it is desired to continue the period of narcosis for some time the mask should not be kept off for long, but only raised occasionally for air. If the respiration indicates the lightening of the narcosis a few more cubic centimeters may be added to the bag; on these lines the anesthesia may be prolonged indefinitely.

Glasgow Medical Journal.

14 Case of Precocious Development. J. Devon.
15 *Treatment of Smallpox by Ichthyol. A. Love.

15. **Ichthyol in Smallpox.**—Love describes the results obtained in the treatment of smallpox by ichthyol. The ichthyol was given in doses of 40 grains, administered in the form of chocolate-coated tabloids, three times in the twenty-four hours. In a certain proportion of cases ichthyol was also applied externally in the form of an ointment. The action of the drug was observed in 100 patients, of whom 67 were males and 33 were females, their ages ranging between 3 and 60 years. The treatment was commenced as soon as the patient was admitted to the ward, and was continued until he was sufficiently convalescent to leave his bed. Of the total cases treated 6 patients (or 6 per cent.) died, but the cases were not selected in any way with regard to severity, although it is probable that the action of the drug would have been better estimated in cases of considerable severity than in those of a milder character. In 30 out of the total nuhmber of cases the eruption was sparse; in 63 it was abundant, and in 5 it was confluent, while in 2 it was hemorrhagic in character. With regard to vaccination, 4 patients were unvaccinated, but in two of these vaccination had been attempted unsuccessfully in infancy. In none of the cases observed was there any indication that the drug influenced the disease as regards either its course or severity. That pustulation was not affected in any way is shown by the fact that nearly all the cases ran a full course, and by the incidence of abscesses in some during convalescence. The course of the eruption, as well as the complications and sequelæ, were precisely those seen among smallpox patients who have not been subjected to any special treatment. The two patients in whom the eruption aborted were

persons who had been well vaccinated in infancy, a considerable degree of immunity being thus indicated, and whose eruption at the time of admission was of a small, dry character usually associated with a modified development of the rash. In a certain proportion of the cases ichthyol was applied externally in addition to the internal administration. The upper limbs were usually chosen for this purpose, because of their accessibility, and the ichthyol was applied by wrapping the arm in lint which had been thickly smeared with the preparation. The effects of this external application were as disappointing as those resulting from the internal administration; indeed, in most cases the stages of maturation and crusting were delayed on the limb treated, the pustules remaining soft and crusts forming tardily.

23. Prostatectomy Secondary to Cystotomy.—André has performed prostatectomy in 24 cases, and in 3 it had been preceded by cystotomy. The intervals were two months, one year and two years respectively. After the bladder had been treated the patients regained strength so that an operation on the prostate became practicable. The general health forbade it at first. His patients were from 65 to 70 years old.

24. Fibrinuria.—Imbert reports 3 cases in which the urine contained fibrin or fibrinogen, independently of hematuria or chyluria. He has been able to find only 9 similar cases reported in the literature. The fibrinuria seems to be connected with some kidney affection, but the latter is extremely variable. Treatment is purely symptomatic, hot baths, injections, laxatives. A milk diet and potassium oxalate did not seem to produce any effect in his cases.

25. Treatment of Operative Injury of the Ureter.—Experimental research on dogs has shown that excellent functional results can be obtained from an anastomosis between the ureters, implanting one in the other, in case of injury to one. The various steps of the procedure are illustrated as performed on large dogs and on cadavers.

30. Psoriasis and "Salve Tights."—For several years Brocq has adopted the practice of having his psoriasis patients put on at night a union suit or tights, to cover the entire body after it has been thoroughly smeared with the proper salve. The salve is rubbed all over the sound skin as well as into the patches of psoriasis, and the patient thus sleeps in an actual bath of salve. The salve-impregnated union suit can be taken off during the day if desired, but is worn every night. He has found that this method materially shortens the duration of treatment, while the drugs can be much less concentrated than when applied by other technics. His favorite formula for the purpose is 15 gm. of oil of cade with 85 gm. of glycerite of starch, made into an emulsion with green soap and oil of cloves. He uses a stronger concentration when only the patches are treated.

31. Diathesis of Autoinfection.—Gilbert remarks that all the passages leading out of the gastrointestinal tract generally contain bacteria, but that these are the species normally found in the intestine. The anaërobic varieties predominate in the depths of the passages, and are always waiting for something to reduce the vitality and resisting powers of the tissues in which they are lurking, when they proceed to set up an inflammation. Appendicitis, inflammation of the gall bladder and gallstone formation are all the work of the germs normally in the intestines, as also pancreatitis and certain other affections. The predisposition to inflammation in these circumstances he calls the "diathesis of autoinfection." He gives a long list of the affections that may result directly from it. They include gallstones, cirrhosis of the liver, angio-pancreatic sclerosis, appendicitis, and probably also mucomembranous enteritis, icterus, stomatitis, tonsillitis and acute articular rheumatism. There is also a long list of affections which follow in the train of the foregoing, such as diabetes, neurasthenia, hysteria, gout, etc.

35. Practical Isolation of the Tuberculous in Public Hospitals.—Barth refers to the sweeping regulations decreed by the Paris authorities a year or so ago in regard to the isolation of tuberculous inmates of the hospitals. The regulations were chronicled in The Journal at the time; they called for the setting apart of certain hospitals exclusively for the tuberculous. These regulations have never been enforced, and tuberculous patients continue to be scattered through the wards of some of the hospitals now as before. Barth has organized a practical system of isolation in the Necker Hospital which apparently answers all the purposes without any commotion. He assigns to the "open cases" of pulmonary tuberculosis a certain part of each ward. Another section is set apart for patients entirely free from tuberculosis, and no tuberculous person is allowed to enter this section except possibly those who show no tendency to cough or spit. Certain spaces are isolated with glass walls about eight feet high, and these are reserved for the doubtful cases and for those too feeble to observe the "discipline of the cuspidor." These isolating compartments are disinfected whenever they change inmates, and the main ward is cleaned morning and evening with damp cloths. The spittoons are filled with a carbolized fluid and each has a cover. They are emptied and boiled each day. All who cough are given pieces of paper which they hold before the mouth when coughing and then throw into a special receptacle. The consumptive knows that he will be sent away from the hospital if he enters the part of the ward devoted to the non-tuberculous or spits on the floor. Bacteriologic examination has been made daily of the nasal secretions from several of the non-tuberculous inmates, selected at random here and there through the wards, even close to the tuberculosis section. No tubercle bacilli were found during the two months in which these examinations were made.

36. Serotherapy of Exophthalmic Goiter.—Hallion reviews the history of this subject, claiming for Ballet and Enriquez priority for the application of serotherapy to this disease in 1894. They were followed by O. Lanz, who used the milk of goats after removal of the thyroid gland, while Moebius gives the serum of sheep after thyroidectomy. All have found that fully as good results were obtained when the serum was given by the mouth as when it was injected subcutaneously. Hallion prefers the blood of sheep or horses, as these animals seem to be better adapted for serum purposes than the carnivora.

Their blood can be used a month after thyroidectomy, and he utilizes the entire blood, believing that possibly the essential curative principle may be connected with the figured elements of the blood. He adds glycerin to preserve the blood, and orders one or two teaspoonfuls a day before meals. Larger doses have not caused any inconvenience, but do not seem to be more effectual than the smaller ones. Enriquez gives three teaspoonfuls a day for one week, then three dessertspoonfuls, and then three tablespoonfuls. The results are sometimes very rapid and striking. The improvement in the patient's condition is unmistakable as the tachycardia and tremor subside. The exophthalmos is more refractory. Secondary affections and complications are also favorably affected at the same time. Breton observed a hemorrhagic pleuritis in a patient with exophthalmic goiter which was evidently arrested by the serotherapy as the general condition improved. The goiter in the exophthalmic variety is less responsive to serotherapy than the typical triad of symptoms.

38. **Food of Paris Working People.**—Landouzy and Labbé presented to the Tuberculosis Congress a large table showing the details of the average diet of 100 men and women of the laboring classes, selected from the applicants at the Laennec Hospital. Lassalle claims that "the social question is a question of the stomach," but that there is a lack of wise provision for the diet of human beings, although stock raisers have reduced it to a science for their animals. To remedy this state of things a society has been formed at Paris, Société de Hygiène Alimentaire, which aims to study the questions in regard to diet from every point of view, and to teach and popularize the lessons learned. The practical study of rational feeding to preserve health, to maintain strength and to ensure the highest working capacity, at the minimum of expense, Landouzy believes, will prove certainly one of the most effectual forces at our command in arresting the spread of tuberculosis. More than this, education in household matters, "domestic education," is one of the best safeguards of both the physical and moral health of a country, as was explicitly stated in one of the resolutions adopted by the International Tuberculosis Congress.

39. **Forests and Tuberculosis.**—Gaulejac shows by statistics that the forest regions of France are less affected by tuberculosis than others. The purity of the air, the rapidity with which the organic waste matters are destroyed by the multiple, purifying functions of the trees, the properties of the essences exhaled by certain trees, all these, he states, supplement the more natural life lived in or near the forests.

41. **Addiction to Heroin.**—Sollier asserts that heroin is proving more toxic than morphin and that addiction to heroin—which is becoming comparatively frequent—entails greater physical and moral havoc than addiction to morphin. In treating 120 cases of morphin addiction he has never had occasion to return to the morphin more than three or four times, and then only from excess of prudence, fearing possible syncope. The syncope in treatment of morphin addiction comes from heart weakness, and if all extra demands on the heart are avoided, there need be no fear of it. In heroin addiction, however, the syncope is respiratory, of bulbar origin. It does not yield to a dose of heroin as the syncope yields to morphin in morphin addiction. If the ordinary measures to restore bulbar action prove ineffectual, the patient is liable to succumb. The only way to avoid danger from this source is to substitute morphin for heroin in treating heroin addiction. After the patient is under the effects of morphin, then treatment as for morphin addiction is commenced. Sollier cites some instances of the baleful effect of heroin, which he affirms should be thrown out of the pharmacopeia, and adds that there will probably be similar experiences before long with dionin addiction. He already knows of a few instances.

42 (XXV, No. 45, Nov. 8.) *Mode of Death in Scopolamin-Morphin Anesthesia.—Comment on meurt dans l'anesthésie générale par la scopolamine-morphine. De Maurans.

42. **Death in Scopolamin-Morphin Anesthesia.**—When this mode of anesthesia was introduced into France De Maurans called attention to the 12 cases in which death had occurred during the anesthesia, and for which the anesthetic was probably responsible. He now cites 10 more fatal instances, and analyzes the reports of them published by the various surgeons. His conclusion is to the effect that any one "using this notoriously unreliable and dangerous technic incurs a heavy responsibility." Experimental research has confirmed the findings in the clinic. The method is merely the revival of the atropin-morphin technic which was abandoned long ago, although atropin is a more stable product than scopolamin. (See Answers to Correspondents, December 9, page 1817.)

43. **Diet in Gout Based on Tolerance.**—During the two years in which von Noorden has made a special study of the tolerance of gouty patients for food containing the purin bodies, he has learned that there is a great difference in individuals in this respect. He put his patients first on a diet free from purin bodies, and determined the proportions of endogenic uric acid. He then gave 400 gm. beef (weighed raw) on two successive days, giving 150 gm. at breakfast and 250 gm. at noon. About 0.24 gm. of purin bodies can be estimated for each 400 gm. beef. About 50 per cent. of the purin bodies vanish in the organism, either from oxidation or from lack of assimilation, but the remaining 50 per cent. may be expected to be eliminated in the urine as uric acid or purin bases. During the two days, therefore, the proportion of purin nitrogen eliminated from the 0.24 gm. purin bodies ingested each day should amount to a total of 0.24 gm. demonstrable in the urine, equal to 0.72 gm. uric acid. The elimination generally occurs during the two days of the test, but may be prolonged under normal conditions into the day or so following. In case of gout, however, the elimination drags on for several days, and the total output is much less than that of normal subjects. We learn by this test whether the gouty patient is able to tolerate this amount of the purin bodies. If he can, there is no reason why he should not be allowed them, but if not, then the amount of purin-containing food must be reduced to ward off retention of uric acid and attacks of gout. It was sometimes found that a smaller amount of the purin bodies was well taken care of by the gouty patient, who had shown himself unable to cope with the original 400 gm. of meat. The amount of uric acid eliminated increased after ingestion of 200 gm. of meat, the total amount being much higher than after ingestion of 400 gm. of meat. The details of a typical case are tabulated. The patient, a man of 55, eliminated an average of 0.462 gm. of uric acid when not ingesting any purin-containing food. After two days of 400 gm. of meat each, he eliminated from 0.458 to 0.544 gm. of uric acid. He was then given 200 gm. of meat, and the amount of uric acid eliminated rose to 0.655 and 0.647 gm. on the folowing days. This patient, therefore, was allowed to eat meat freely to the amount of 200 gm. a day. Larger amounts would certainly have entailed retention of uric acid and attacks of gout. The tolerance of gouty individuals should be determined just as we determine the tolerance of diabetics. In both cases, however, the tolerance is not an invariable figure; it varies in the course of the disease, and these variations should be supervised and the diet modified to correspond. In von Noorden's experience, while the intake of purin bodies was thus regulated, the therapeutic results attained far surpassed those observed with any former method of treatment, either dietetic or medicinal.

44. **Pathology of Trachoma.**—Goldzieher remarks that bacteriology has not afforded much aid in the study of trachoma, but that the history of the affection shows an unmistakable connection with gonorrhea, as he relates in detail. He does not affirm that blenorrhea and trachoma are identical, but asserts that there are certain forms of chronic, infectious inflam

mations of the eyes, originating in blenorrhea, which it is impossible to differentiate from trachoma. The diagnosis of trachoma should not be based on the granulations alone, but on the evidences of infectiousness and on the long duration of the process.

45. **Thoracal Ostealgia.**—Hampeln has observed cases of ostealgia affecting the body of the sternum, the xiphoid process, or the false ribs. The pains in the first group suggest those of *angina pectoris*. In all, the bones seem to be the seat of continuous or paroxysmal, and sometimes radiating pains, and display sensitiveness to pressure. In some of the cases a tendency to gout was probable, but in others the signs were those of a general neurosis. In a considerable proportion of the cases there were no indications of any other affection, and consequently the ostealgia must be referred to an unusual sensitiveness of the bones in question. Since he has been studying the subject he has found that many apparently healthy persons feel pressure on certain ends of bones or bony processes as pain, although previously unconscious of this sensitiveness on the part of the bones. He regards this disposition to painfulness as almost physiologic for certain bones. In times of increased irritability, hysteria or neurasthenia, this predisposition may be magnified into actual ostealgia.

47. **Cure of Superficial Epithelioma with Sunlight.**—Hirschberg relates that he spent a month last winter at Caux, on Lake Geneva, at an altitude of about 3,400 feet. He had long had an epithelioma on his ear, which measured about 1.5 cm. by 0.5 cm., but after two weeks of out-of-door life among the mountains he found that the epithelioma was being cast off. He then exposed it more systematically to the sunlight, and by the end of the month nothing was left but a minute bunch which he easily removed by cauterization after his return. The ear is now entirely normal; there have been no signs of recurrence during the eight months since. He urges the establishment of open sun-resorts among the mountains for this purpose, the solarium being open to the sun and air, as glass prevents the passage of most of the ultraviolet rays. If Boubnoff's experiences are confirmed by others, the light treatment can be much simplified. Boubnoff announces that ordinary woolen and cotton clothing does not prevent the passage of the chemical rays. They pass more readily through the uncolored than colored fabrics. Of the colored fabrics blue allows more of the rays to pass than other colors, and black least of all. His experiments were made with diffuse daylight; the results would probably be better with direct sunlight.

55 Recovery After Extraction of Bullet from Posterior Wall of Heart.—Schussverletzung des Herzens. Z. v. Manteuffel (Dorpat).

49. **Glycosuria After Ether Anesthesia.**—Röhricht has examined the urine of 100 patients after operations on account of cholelithiasis, struma, osteomyelitis, elephantiasis, cancer, hernia, varices, etc. Glycosuria was observed in one or more of each group, the total being 12 cases. Only one of the patients was under 20 and none over 60. Of the 12 positive cases, 8 were men. Only one out of 9 other patients who had undergone major operations under local anesthesia showed glycosuria, while it was not detected in 22 other patients after traumatism without anesthesia. On the other hand, out of 6 patients who had been anesthetized with ether, without an operation, 2 exhibited spontaneous and one alimentary glycosuria.

64 *Distribution of Typhoid Fever.—Die Verbreitung des Unterleibstyphus. A. Gottstein.

56. **Flagella of Spirochaeta Pallida.**—Schaudinn gives illustrations of the principal spirochetes and states that the pallida is the only one he has yet discovered which sometimes has a flagellum at one or both ends. In one instance he found two flagella at one end and one at the other. The old Loeffler bacterial flagellum stain shows them up best. Some of the other varieties of spirochetes have an undulating membrane, but he has never found this in the pallida. On account of these differences in the latter, setting it apart from the genus spirochæta as well as from the spirillum, he suggests that it is evidently a new genus and proposes the name of Spironema for it.

59. **Further Improvement of Biologic Test for Blood.**—Uhlenhuth relates experiences which demonstrate that the biologic precipitation test is the most delicate means at our disposal to detect relationships between animals and birds. It shows the close "blood relationship" between hens and pigeons, between rabbits and hares, and so on, and it may solve interesting questions in racial differences between human beings. He describes a method of "crosswise immunization" which shows that the rabbit organism, for instance, is able to form precipitins active against the blood albumin of the closely related hare. He also shows that it is possible by this means to differentiate the blood of each species from that of the other with mathematic precision. He injected his rabbits with a solution in physiologic salt solution of dried hare's blood fully four years old. The serum of the animals soon showed pronounced precipitating power in respect to hare's blood.

64. **Typhoid Fever in Prussia.**—Improved methods of caring for typhoid patients have reduced the mortality in a constant ratio from 2.64 to 0.81 per 10,000 inhabitants since 1887. Gottstein comments on the rapid spread and rapid extinction of the typhoid epidemics, most of them being restricted to a few weeks, even the famous one at Gelsenkirchen in which 11,357 cases occurred in 1901. This epidemic appeared and subsided within a few weeks. The largest number of cases of typhoid in places where the disease is endemic does not always occur in July, August and September, but is sometimes observed in February and March. An increase during the late summer is frequent, but is not an essential characteristic of a typhoid epidemic. He remarks also on the way in which certain districts suffered from typhoid during the summer of 1905. They were mostly industrial regions where the disease is more or less endemic, but even in Berlin the number of cases of typhoid, which was 45 in 1904, during last summer reached the total of 113. Throughout Prussia there were 1,475 cases, while in the preceding summer there had been only 1,092.

72 *Eye Affections Due to Autointoxication.—Augenerkrankungen durch Autointoxikation. Elschnig (Vienna).

65. **Heart Affections.**—Treupel's address is the final summary of a postgraduate course on this subject. In determining the size of the heart and its parts, he has found orthodia-

graphic examination of the heart—as F. Maritz of Greifswald has worked out and perfected the technic—a great progress in this line. (Moritz' communications on the subject have been mentioned in The Journal from time to time. His latest article opened volume LXXXII of the *Deutsches Archiv f. klin. Med.*, 1905.) In conclusion Treupel announced the extremely satisfactory results of resection of the ribs in a case of extensive obliteration of the pericardium and adhesion of the heart to the thorax wall, which had been demonstrated before the operation. The patient was a man of 29 who had presented symptoms of heart trouble since an attack of articular rheumatism at 17, and had been treated for nephritis a year before. During the last few months he had experienced oppression in the heart region which increased toward evening and caused great distress and agitation. His sleep was very restless, even under morphin. There were no indications of disturbance in compensation, no edema or ascites, but waves were evident in the jugular veins and there was a positive venous pulse. The heart was excessively large, bulging out the chest wall. The mitral murmur was loud, systolic, almost musical, while the aortic murmur was diastolic, prolonged and gushing. The varying relations between the heartbeat and the carotid and radial pulse are shown in several diagrams. The heart action was moderately rapid, and occasionally the carotid pulse occurred synchronously with the retraction of the chest wall over the heart. In spite of rest, ice, digitalis and morphin, the subjective disturbances were not improved, and part of the chest wall over the heart was removed. This relieved the patient to a remarkable extent and he is now able to sleep well. About 7 cm. were resected from the fourth and fifth ribs over the heart, disjointing them from the sternum.

67. **Agar in Treatment of Habitual Constipation.**—Schmidt believes that chronic constipation in certain cases is due to the unusually good digestion and utilization of the food, leaving so little residue to be passed along that the intestines are not incited to peristaltic action. The residue being so small, there is very little putrefaction, not enough to stimulate the intestines to peristalsis by the gases and other products evolved. The feces in chronic constipation of this kind are hard, solid lumps, with little odor, and show few indications of fermentation or putrefaction. Aside from the difficulty in defecation and the accessory neurasthenic general manifestations, such individuals rejoice in undisturbed good health, not disturbed by gas formation or other phenomena suggesting excessive putrefaction. Such patients can take, without much reaction, a purgative which would cause protracted diarrhea in others. Even when entire wheat bread, salads, fruits or nuts are eaten in abundance, he states, the constipation persists, as the digestive organs are able to digest the cellulose more or less and the stools remain hard and scanty. What is needed is something that will increase the bulk of the stools and make them softer, more watery and less compact. Schmidt thinks that this result may be obtained with agar agar. It contains 0.6 per cent. cellulose, and when it swells up in water it gives up the water very slowly and is not modified by putrefaction. Bacteria do not liquefy agar. He has been experimenting with it and found that it answers the purpose very well. He uses the kind that comes in long strips, and flakes and cuts it up into small bits, like scales. It swells in the mouth and still more in the stomach, and appears unmodified in the stools. The stools become softer and more watery, and are usually passed much more readily. The agar does not irritate the alimentary canal in the least (as much as 25 gm. of the dry agar were taken daily in some of the tests without disturbance). When ingested in the form of a powder it is liable to cause diarrhea and occasionally colic, probably from the more rapid and intense swelling of the agar. The stools become soft and copious, but the intestines have been so long accustomed to the constipation that they do not respond readily to stimuli. Consequently, although the stools have the normal aspect they are not passed spontaneously in every case. To remedy this he adds a very small amount of a 25 per cent. aqueous extract of cascara to the agar—not enough to have a purgative action, but merely enough to supply the stimulation realized by the natural putrefaction in normal stools, but missing in these cases. He has treated 25 patients with chronic, habitual constipation on these principles, and essential and permanent improvement was obtained in every instance. Fluid paraffin is the only other substance which he has found with similar properties. He has given as much as 30 gm. a day of the paraffinum liquidum of the German pharmacopeia without disturbances, and has also had favorable experiences with white and yellow vaselin. This also requires a little 10 per cent. cascara extract to ensure spontaneous defecation. The agar is taken more readily than the vaselin by the patients, even when the latter is given in capsules. Some of the vaselin is evidently assimilated. In an illustrative case cited, the patient passed 38 gm. of hard, dry stools in three days on a test diet. During the three following days he ingested 66 gm. of the dry agar scales and passed in these three days 87 gm. of feces with more than twice as much cellulose as during the preceding period. The agar not only passed unmodified, but it prevented to a certain extent the abnormal utilization of cellulose. Agar has no taste at all. A teaspoonful to two tablespoonfuls are taken during the day in apple sauce or something of the kind, a total of 1.5 to 8 gm. It has to be taken regularly day after day, and in the severer cases its action must be supplemented by other measures. Its sphere is mostly in the mild and moderately severe cases, either of the atonic or spastic varieties.

72. **Eye Affections Due to Autointoxication.**—For ten years Elschnig has been making a special study of gastrointestinal autointoxication in the etiology of ocular affections. It is especially important as a cause of interior ophthalmoplegia, more rarely of paralysis of the external muscles of the eye and affections of the optic nerve. He thinks that it is also a cause of affections of the cornea and sclerotic, recurring keratitis, scleritis and periodical episcleritis, and affections of the uveal tract, especially in recurring iritis and many cases of insidious iridocyclitis. In certain cases of the latter groups there are symptoms of inherited lues, but antisyphilitic treatment gives negative results. It is more than probable that the inherited lues has caused changes in the digestive tract which predispose to gastrointestinal autointoxication. In all these eye affections, dietetic and therapeutic measures to regulate the digestive tract essentially improved or cured the eye affections after failure of all other forms of treatment.

73. **Operative Treatment of Aneurisms.**—Kikuchi is surgeon general of the Japanese army, and in his experience in the field he evolved a method of treating aneurism which proved remarkably simple and reliable. On consulting authorities he found that it was much like Sime's modification of Antyllus' technic. He had occasion to observe 58 cases of aneurism, the result of bullet wounds during the war. The femoral artery was involved in 18 and the popliteal in 9, the subclavian in 5 and the brachial in 8 cases. The advantages claimed for his technic are that the operation is materially shortened and simplified, and the part of the vessel resected is comparatively small. The main artery is not ligated, but merely the afferent and efferent vessels belonging to the aneurism with their branches. A tourniquet is applied to the limb and the aneurism is exposed, incised, evacuated and wiped dry. The bullet hole generally faced the center of the body of the tumor, and it was always found to be the source of the hemorrhage. In doubtful cases a bougie may be passed through it. The part containing the hole is then tied off and resected, and the injured parts of the wounded vessel are tied off and resected on the inner side of the sac membrane.

77. **Splenectomy for Echinococcus Cyst.**—Kablukoff reviews the cases of splenectomy on record to date, a total of 278, according to his figures. The operation was undertaken in 79 cases on account of malaria, with 23 deaths; in 94 on account of idiopathic hypertrophy, with 38 deaths; in 29 on account of leukemic hypertrophy, with 26 deaths; in 32 on account of displacement of the organ, with 2 deaths, and in 4 on account of cancer, with 1 death. Only 9 cases of splenectomy on account of echinococcus cyst are known to him, one of the number having been reported by a Russian surgeon. Kablukoff reports another successful case of this group. The patient was a woman of 36, and the affection had been diagnosed as a sarcoma of the left kidney. In 6 other cases he merely evacuated the cyst in the spleen by Lindemann's technic, with good results in all.

80. **Complications of Aneurism of Aorta.**—Reisgoff describes with great detail the clinical and postmortem findings in a case of aneurism of the aorta complicated by thrombosis with obstruction of numerous arteries. The patient was a man of 36. The case shows that obstruction originating in the arch of the aorta does not necessarily cause serious disturbance in the nutrition of the tissues previously nourished by the obstructed arteries in the neck, the carotid, subclavian and innominate. Collateral circulation develops, and the organism soon adapts itself to the altered conditions. In the present case the aneurism was in the descending aorta and in the arch, and the left carotid artery was found completely obstructed, also the mouth of the right coronary artery, while the left innominate and subclavian arteries with ramifications were only partially obstructed.

85. **Extragenital Syphilis.**—The patient in the case reported was a young woman of good family, who presented a chancre on the lower lid, followed by the symptoms of constitutional syphilis. When on her wedding trip a chambermaid noticed a stye on the bride's eye and offered to cure it by rubbing it. She used her saliva-moistened finger, and the result was the transformation of the stye into a syphilitic chancre, followed by the symptoms of constitutional syphilis.

88. **Tumor in Cerebellum of Boy of 9.**—Vinokuroff reviews the literature on the subject of tumors in the cerebellum before giving the particulars of his case. Headache, vomiting and indications of congestion in the fundus of the eyes were all the symptoms observed, but at the autopsy a large solitary tubercle was found in the left half of the cerebellum, with caseous degeneration in the center.

89. **Differentiation of Noma.**—Kissel's article is based on a material of 46 cases collected in the course of eleven years. There was a history of preceding measles in 25, of typhoid fever in 4, of dysentery or whooping cough in 2, and of double pneumonia in 1 case; the antecedents were not known in 12 cases. Ulcerative stomatitis developed as an independent process in most of the cases. The first signs of the affection are slight swelling of the cheek with very little pain or congestion. The infiltration shows a very hard center, feeling like cartilage. In some cases the gangrenous process develops in the bones of the face, the perforation of the cheek not occurring until just before death. In ulcerative stomatitis Vincent's bacilli and spirilla are found in great abundance, but they are scanty or absent altogether in case of true noma. In none of Kissel's cases was there a transformation of ulcerative stomatitis into noma. He urges the importance of careful, daily examination of the mouth in all children debilitated by an acute infection. If this is done systematically, then cases of noma will be detected in the incipient stages. In rare cases the destructive process may affect the bones of the face without involvement of the skin. In one case he was called in consultation to see a little girl of 10 with typhoid fever. The surroundings were hygienically of the best and the child had been under constant medical supervision. He examined her mouth and found an unsuspected extensive gangrenous process in the soft part over the alveolar processes in the right upper jaw and roof of the palate. In another case, a girl of 5 lived in a neighborhood where there had been several cases of ulcerative stomatitis. She developed a gangrenous process in the cheek which did not reach perforation, but otherwise was typical noma, terminating in recovery. As a rule, he found the lymphatic glands less involved in noma than in ulcerative stomatitis.

90. **Operation for Symblepharon.**—Pravosud thinks that all methods of remedying symblepharon have so many defects that a new technic is desirable. He advocates a plastic operation which consists in making a horizontal incision to enlarge the interpalpebral slit to the edge of the orbit on each side. Two incisions are then made downward from the ends of the horizontal incision, at right angles to the first incision, for a distance of 1.25 cm., slightly converging below. A knife is then passed through the lid from one of these perpendicular incisions to the other, forming a flap whose base is parallel to the interpalpebral slit, while one side follows the base of the nose and the other corresponds to the outer side of the orbit. A piece of mucous membrane is then taken from the cheek and fitted over the raw surface left as the flap is turned down. The upper edge is sutured to the eyeball and the lower edge to the edge of the turned-down flap. Three loop stitches are then taken through the applied flap and the lower lid at the base of the flap. These loops hold the mucous membrane down to form a conjunctival sac, and are tied outside of the skin when the lower lid with its new lining is turned back and sutured in place.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Address

PATHOLOGIC PHYSIOLOGY, A NEGLECTED FIELD.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PATHOLOGY AND PHYSIOLOGY, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION PORTLAND, ORE., JULY 11-14, 1905.

WINFIELD S. HALL, Ph.D., M.D.
Professor of Physiology, Northwestern University Medical School.
CHICAGO.

Not many generations ago physiology was taught in connection with anatomy only, and was a simple statement of the functions, as then understood, of the various structures described by the anatomist. It was Haller, who in his "Elements of Physiology,"[1] outlined the field of physiology and clearly established the boundary line between that subject and anatomy. Since Haller's time physiology has been recognized as a separate branch of medicine and soon after the publication of Haller's Elements, provision began to be made by the medical faculties for the teaching of this subject in a separate department.

Begun as an appendage of normal human anatomy, it continued as normal human physiology, gradually broadening into animal and plant physiology. Great as has been the activity in the field of morphology, that in the field of physiology has been scarcely less until the mass of facts and principles of physiology already firmly established is so great that the two years' course in experimental and didactic instruction in physiology now usually given in medical schools suffices simply to present such fundamental principles and facts of the science as may be applied later in clinical medicine. Furthermore, great as this material is, it includes only the discussion of the functions of the normal individual. In other words, the course of physiology as now given is one in normal physiology only.

If we turn now to the subject of pathology as presented to-day in our medical schools, we find that histopathology—presented usually in the second year—deals almost exclusively with modifications of the structure of the cells and tissues of the body, while the didactic course accompanying the microscopic work deals usually with the field of general pathology covering such topics as hydremia, anemia, hemorrhage, transudation, thrombosis and embolism; atrophy, degeneration, pigmentation and necrosis; hypertrophy, hyperplasia, metaplasia and regeneration; inflammation; parasites, animal and plant; the relation of micro-organisms to disease, infection and immunity; infectious diseases; tumors.

One searches the chapters of general pathology in vain for any sections that deal adequately with the problem of the physiology of disease.

Taking up the field of special pathology as usually presented in the third and fourth years of the medical course, one finds that the postmortem furnishes the material for study. The points of fundamental importance at the postmortem as it is conducted by our leading pathologists are: (1) To confirm, or disaffirm, the diagnosis of the condition as made by the attending physician; (2) to gain information that will make the diagnosis of similar cases more secure in the future; (3) to increase our knowledge of diseased conditions of the body. With these ends in view it is customary to preface the postmortem examination by the reading of the clinical history of the case in hand, followed by, first, an examination of the body to determine gross conditions, demonstrating all evident changes of the gross conditions as the examination proceeds; second, preserving portions of each diseased tissue or organ for later microscopic examination. Such a postmortem examination requires from one to two hours, not including the many hours that may be later devoted to the study of microscopic changes.

The accumulated material from the numerous postmortems affords museum material for gross study as well as microscopic material for study in connection with various topics in clinical pathology.

I believe that the above account, though brief, gives a fair summary of the work now being accomplished in our pathologic laboratories. I think it is not unfair to other departments of the medical school to say that the work of the pathologic department is the most important work in any one department of the medical course, and the work now given in the larger institutions could hardly be improved on in the time that is devoted to it.

It appears to me, however, that a very important phase of pathology and physiology has as yet received scant attention from medical teachers. The postmortem affords a golden opportunity for the study of the clinical history, particularly of the symptomatology, of the case in the light of the postmortem findings. The symptomatology of disease represents nothing more or less than modified functions as observed in diseased conditions. That there is a definite relation between the symptoms observable in a disease and structural changes that go on in the cells, tissues or organs can not be gainsaid. It may be difficult to establish this relation, but the pathologists should not be satisfied with their work until every disturbance of function has been traced to some disturbance of structure. The disturbance of structure accompanying malnutrition might be so slight as the simple difference in the zymogen granules of the pancreas, or in some obscure physical or physico-chemical change in the cells of the thyroid gland, while a derangement of the mind might be associated with a slight change in the Nissl granules in the cortical cells of the brain, or in a slight modification in the space relations ("contiguity") of cell-processes in the brain centers.

As stated above, the postmortem affords an opportunity for the study of the relation of disturbed function (symptomatology) to the diseased structure. Such an attempt on the part of the pathologist to enter into the discussion of this problem in connection with the postmortem examination would involve the expenditure of at least twice as much time as is usually now spent on a postmortem examination. In many cases this would entail the necessity of making fewer postmortem examinations than is desirable.

---

[1] Elementa Physiologiæ, in six volumes, 1757-1765.

The question might be asked, "Why should not the physiologist cover this field and present to the students normal and pathologic physiology?" We will say in answer to that question: The physiologist presents normal physiology during the first two years of the medical course. The students have not progressed far enough in the study of pathologic conditions to enter understandingly into a consideration of the relation between symptomatology and pathology. Thus we find that important as this field is, neither the physiologist nor the pathologist—one for the lack of preparation of his students, the other for the lack of time—can take up this most important subject. The student therefore enters on the study of clinical medicine and surgery with a knowledge of normal structure and function, and also a knowledge of diseased structure, but no knowledge of diseased function. The clinician, in his presentation of a clinical case, may or may not discuss the symptomatology of a case from the standpoint of physiology. If an attempt is made at this at all it is more or less incidental to the discussion of diagnosis, of differential diagnosis and therapeutics. The relation of symptomatology to diagnosis on the one hand and to therapeutics on the other, so far overshadows in the mind of the clinician its relation to pathology on the one hand and normal physiology on the other, that very little attention is given to these last two phases of symptomatology.

I believe that the most important step to be taken in scientific medicine is, first, to determine and next to teach every student of medicine the relation between symptomatology and pathology, and this teaching should be a systematic course given to students taking clinical medicine and surgery, and should be divorced from any discussion of diagnosis or therapeutics, so that the undivided attention of both student and instructor would be directed to the solution of problems of the relation of modified function (symptomatology), to modified structure (pathology). It might be given by a pathologist, a physiologist or a clinician. In either case the preparation of the instructor could not be deemed adequate unless he were well versed not only in physiology and pathology, but also in clinical medicine.

One naturally asks at this point whether there exists a literature of this subject. Krehl, professor of internal medicine, University of Strassburg, Germany, has prepared a most admirable work of 600 pages entitled "Pathologic Physiology; A Treatise for Students and Physicians."[2] The third edition of this work was published in Leipsic in 1904. The first edition appeared about a decade ago. Earlier editions were not translated into English, and it has had a very limited use in Germany and among advanced men in other lands. An English translation of this admirable work is just now completed by Dr. Hewlett of Johns Hopkins University. Professor Krehl treats this subject from the standpoint of the clinician following the classification of the pathologist, and harmonizing his treatment at every point with the latest findings in physiology.

The question of the classification of the subject-matter is one of no small importance, and is a question to which I have given considerable thought. For the purposes of the physiologist and the pathologist, Krehl's method is advantageous. It is, however, questionable if such a classification would make the work as convenient as a manual for the student and practitioner as would a classification on the basis of diseases, following that of works on internal medicine.

A preliminary chapter or "part" of such a treatise should deal with general pathologic physiology, setting forth the relation between the various disturbances of function and various lesions of disease. For example: Variations of pulse, with causes of same; variations of peripheral circulation, with causes for same; variations of distribution of blood, with causes of same; variations of rate or character of respiration, with causes; variations of digestive processes, with causes of same; and so on briefly throughout the list of body functions.

Following this should be the main body of the treatise in which diseases of the circulatory system might occupy the opening chapter. Taking up any particular disease there should be a brief description of a typical case as to etiology, pathology and symptomatology. Under the head of pathologic physiology, each symptom should be discussed as to its causes and its relation to the pathologic findings. Diagnosis and treatment need not be mentioned. The discussion of typical cases of each disease would suffice.

I present a plea for the preparation of such a manual as above outlined and for such a course as above suggested, because I believe these are the most urgent needs of medical pedagogy.

Original Articles

THE ABRUPT ONSET OF TYPHOID FEVER.*

MORRIS MANGES, M.D.
Professor of Clinical Medicine at New York Polyclinic Medical School; Visiting Physician to Mount Sinai Hospital.
NEW YORK CITY.

There must be many variations in the onset of a disease, the course of which may be so mild as to be practically unnoticed, or which may kill after an explosive course of only a few days.

Especial stress has recently been laid on the variations in the onset of typhoid fever, as if these irregular cases were a new feature. It is probably nearer the truth to assume that the great improvements in the diagnostic methods in typhoid fever, especially the Widal reaction, have established the identity of a fairly large number of cases which formerly escaped recognition, and by reason of this, it may be added, were undoubtedly largely instrumental in spreading the disease. These irregular cases are much more frequent in infants and children than they are in adults; yet I prefer to restrict my remarks to-day to some of the irregular cases in adults which are characterized by an abrupt onset. These cases are of great practical importance, since rarely is the diagnosis more essential and at the same time more difficult to establish than in some of these patients.

A striking proof of these contentions may be found in the paper published by Curschmann[1] of Leipsic, which was rendered necessary by the sudden and dramatic death of a member of the royal house of Hessen from an abrupt case of typhoid fever.

---

[2] Pathologische Physiologie, 3rd Edition, by Dr. Ludolph Krehl. Published by Vogel, Leipzig, 1904.

* Read before the Twenty-second Annual Meeting of the New York State Medical Association, held at the New York Academy of Medicine, Oct. 17, 1905.

[1] Deutsche Med. Wochenschrift, April 21, 1904.

The high mortality of these cases makes their early recognition imperative, a task which is frequently made difficult by the great variations in the clinical picture. These variations emphasize the general nature of the infections of typhoid fever, since any part of the body may be the seat of the initial manifestations, and it is the sudden development of these local symptoms, combined with the features of a general infection which renders the picture so protean.

As regards the frequency of this form of onset, a careful study of the cases at Mt. Sinai Hospital showed that it occurred in about 10 per cent. of all cases.

The recognition of the abrupt onset is by no means new, since it was first described by Chomel in 1834, in a number of cases presented in his *Clinique Medicale.* No further attention was paid to these observations until Maurice Raynaud referred to them in 1876. In 1884 De Mussy reported a number of cases, terming this method of onset "explosive." Since then a number of French writers, chief among whom are Potain and Widal, have added cases. In this country Pepper and Stengel[2] have also called attention to this subject. The statement of these authors, however, that Moore was the first to call attention to this class of cases in his text-book on Eruptive and Continuous Fevers in 1902, is incorrect, as is shown by the references which I have just given.

The most complete presentation of this subject is that of Wormser,[3] who draws attention to the high mortality in this class of cases, a statement which my own experience confirms. Widal has also studied these cases and has noticed the very early occurrence of his reaction in this group, it being positive on the third to the sixth day, and he therefore believes that the explanation of the sudden invasion is in many cases not to be traced to the shortness of the disease, but to the fact that the typhoid bacilli have "developed silently" in the organism. In these cases it is also probable that the bacilli may be unusually virulent, or that they may be associated with other antecedent infections, such as grip, malaria, tuberculosis, etc., which have lessened the powers of resistance of the individual, or, on account of the presence of a mixed infection, have favored the unduly rapid and virulent growth of the typhoid bacillus.

Before proceeding further we must carefully distinguish two important groups of cases with an abrupt onset. First, those which really are abrupt and which are the cases especially referred to in the preceding remarks; and second, those which seem to be abrupt and yet are actually not so—I refer to those melancholy cases of walking typhoid, by no means infrequent, in which the onset of the disease has been insidious and which invite medical aid only after the appearance of some catastrophe, such as perforation, hemorrhage, peritonitis, etc. These cases are too familiar to require any special consideration. How common they are may be readily inferred from the fact that in England typhoid fever is included among the causes of sudden death.

Cases of abrupt onset may be ushered in variously, either with chills, single or repeated, severe pains in the abdomen, head or other parts of the body, or violent delirium; or they may simulate cases of appendicitis, nephritis, pneumonia, pleurisy, grip, etc. Then, too, we have cases of sudden onset which act like diphtheria with throat lesions, or cases with marked hyperpyrexia; while of still another type are the hemorrhagic cases. An unique form of sudden onset to which I have seen no reference occurred ten years ago in a young adult, in which the initial symptoms were a marked tachycardia and heart failure. It will thus be seen that the abrupt onset presents a very considerable degree of variation which will tax the diagnostic skill of even those who are expert in the disease.

Closely allied to the cases of abrupt onset and to be differentiated from them, are some of the cases of paratyphoid fever, the sudden onset of which brings this class of cases into close relationship with the group under discussion.

A few illustrative cases may be cited. The meningeal type is one of the most common of these cases of abrupt onset.

An interesting example of this occurred a number of years ago in my service at Mt. Sinai Hospital. A boy of 14 was admitted comatose, with a high fever, slow pulse and all the evidences of severe brain mischief. The history given by his parents was that while at play some days before he had fallen down a flight of steps and had been picked up unconscious, in which state he had continued, the fever having also persisted for the same length of time.

Examination of the optic discs by Dr. Gruening showed congestion; a lumbar puncture yielded clear cerebrospinal fluid, which was under increased pressure; examination of the ears and skull negative; moderate enlargement of the spleen was referred to the fever. The case was considered a surgical one until on evening rounds, Dr. I. Straus, who was house physician at the time, discovered a few roseola. On the next day a blood examination gave a positive Widal reaction.

Some of these abrupt meningeal typhoids closely resemble cases of cerebrospinal meningitis. In passing, I might state that the differentiation of these two classes of cases is usually very easy, since a simple leucocyte count will usually make a differential diagnosis possible, as never have I failed to find a high leucocyte count (above 16,000) in cases which proved to be cerebrospinal meningitis, while a low count of 3,000 to 5,000 was invariably present in the cases which developed as typhoid. The lumbar puncture, of course, gives additional diagnostic information. Clinically, however, the cases for a number of days may run an absolutely identical course.

The lungs and pleura when primarily attacked by the typhoid bacilli give us still another form of sudden onset, viz., the pneumo-typhoid and pleuro-typhoid, which are too well known to require any further description. This group may include cases where the sudden onset is so distinctly pulmonary that for a long time they are regarded as being acute tubercular pneumonia. An example of this kind occurred in the practice of Dr. S. V. Haas, where the exact diagnosis of typhoid fever was not made until the Widal reaction was positive in the fourth week. Until that time the case was regarded as being probably an acute pulmonary tuberculosis, the onset, course and the physical signs in both lungs fully warranting this supposition.

Another type of abrupt onset is where the patient is able to give not alone the day on which the disease began, but the exact hour from which he passed from a condition of apparent health into that of being seriously ill. These cases of abrupt onset are associated either with severe chills, fever, violent pains in the head or general pains in the back or other parts of the body, so that an attack of rheumatism or grip is suspected.

Of the cases with an onset of pain I need not say much, since this is a form which is sufficiently common.

---

[2] Philadelphia Med. Jour., vol. 1, 1898.

[3] "De Début Brusque de la Fièvre Typhoïde," Thèse de Paris, 1901.

Two classes of pain might, however, deserve a little further consideration. One is that form of abdominal pain which is especially referred to appendicitis. The clinical association of appendicitis and typhoid fever has been discussed so fully that I may permit the simple mention of this type to suffice without citing any special cases, except two, which may deserve some notice.

1. *The patient* was a boy, 10 years old, in the practice of Dr. W. G. Eckstein, who, while playing, received a kick in the abdomen. After reaching home he suffered from nausea and vomited; the temperature rose to 100.5 degrees, but on the next day he was perfectly well. Two weeks later, after eating lunch, he vomited and then complained of abdominal pain. four hours later the temperature suddenly rose to 105 degrees; there was very marked prostration, but there were no other symptoms except abdominal pain and distension and the fever. On the next day the same conditions persisted, and the boy looked very sick. The tongue was dry and coated; the abdomen was distended; there was tenderness over the abdomen, being especially pronounced over the appendix. The temperature persisted at 105 degrees. Dr. Gerster, who saw the case in consultation, made a probable diagnosis of appendicitis, but advised waiting for further developments before operating. On the following day the same conditions prevailed, the temperature being still between 104.5 and 105 degrees. The Widal reaction was positive only in high dilutions. On the following day the roseola appeared. The subsequent course was an uneventful recovery.

2. Another example of abrupt onset, with severe abdominal pain, like appendicitis, but which was peritonitic, has just been published and deserves mention.[4] The patient was a 6-year-old child who had a very short attack of measles of only three days' duration. Two weeks later she was suddenly taken ill with fever, vomiting and abdominal pain. Two days later the vomiting became freed and the intensity of the pain was so great and their localization such that the diagnosis of appendicitis seemed probable. Ten days after the onset the patient died. At the autopsy the peritoneum was found to be cloudy, with deposits of fibrin in the vicinity of spleen. Otherwise the abdomen was absolutely normal, except in the lower portion of the ileum, where there was a superficial typhoid ulcer.

Josias directs especial attention to the sudden onset of the symptoms, with vomiting, to the rapid and fatal cause and to the perforations, which were not due to a perforation, but to the dissemination of the toxins through the intestinal walls.

The other variety referred to of sudden onset with pain is that of severe pain in the head, which is often very puzzling. The meningeal type I have already mentioned, but this does not include all these cases. As you know, the headache of typhoid fever is usually the characteristic frontal headache. This frontal pain may indeed be so severe that diagnostic errors may result, an example of which is the following case which occurred in the practice of a competent physician in a neighboring city. A young man was suddenly taken with fever and very severe frontal headache. Examination of the nose revealing a marked swelling of both middle turbinates, and there being marked local tenderness over the sinuses and the corresponding portions of the nose, the diagnosis of local disease of the nose was not unwarranted. This view was confirmed by a specialist who was summoned from this city, and the middle turbinate bones were immediately operated on to secure drainage. The headache, local tenderness and fever persisting in spite of this, the specialist was again called in, and he again insisted on more drainage from the frontal sinuses. To secure this both frontal sinuses were opened. To the chagrin of the attending physician typical roseola appeared on the following morning, and the patient successfully passed through an ordeal of typhoid fever.

Another type of sudden onset is that which is marked by sudden high fever, which may or may not be associated with chills. The rise of the temperature is so rapid that within twenty-four to thirty-six hours it reaches its maximum of 105 to 107 F., and the course reminds one of some severe poisoning rather than of typhoid fever. Death occurs usually at the end of the first week, the patient seldom surviving beyond the second. These foudroyant cases, as they have been called by Curschmann, are fortunately rare. I myself have seen but one, the temperature rising to 111 F. shortly before death on the tenth day. The only complication present was a lobar pneumonia, which developed on the ninth day.

The hemorrhagic form of typhoid fever is also often ushered in with sudden onset and runs a brief and rapidly fatal course. These cases are often mistaken for typhus fever. The hemorrhagic form is not always ushered in suddenly, for the only case of this form which I have seen developed in the ordinary fashion and did not show its hemorrhagic form until the latter part of the disease.

Malaria may be associated with the sudden onset of typhoid fever, the relations of which have been well brought out by the experiences in the recent Spanish war, namely, that malaria is apt to complicate the beginning and the end of the disease, but is not a factor of the disease in its fully developed stages. Closely allied to this question is the occurrence of chills at the onset of the disease. Chilliness or repeated small chills are extremely common, occurring in 33 per cent. of the cases at Mount Sinai Hospital. Repeated severe chills without any malarial affection also occur (2 per cent. in all cases). Some forms of this have already been given in some of the variations previously noted. I believe that the abuse of coal tars and other antipyretic drugs has been given undue prominence as the causation of chills at the onset of typhoid fever. While this might have been true some years ago when the coal tars were so recklessly used, yet now it is scarcely to be assumed.

Sudden onset in the throat characterizes a class of cases which is rather rare, the onset in the throat being either in the shape of characteristic Bouveret ulcers or severe pharyngitis. Diphtheria of the pharynx may be associated with a sudden onset of the disease in some cases, examples of which I have already published.[5]

Another type of sudden invasion is illustrated by a case which occurred in the practice of Dr. Berg of this city. A young married woman who was well enough to be out to hear the returns of the presidential election, was suddenly taken ill two days later with high fever, for which no explanation could be found beyond an acute nephritis, the urine boiling almost solid and containing characteristic casts. For four weeks she ran a continuous temperature with delirium, and although she was seen by some of the best clinicians of this city, no explanation could be given beyond the fact that she had nephritis and continuous fever. Independently, the Widal reaction was continually sought for in vain by Drs. Park and Libman. With the fall of the temperature the urine cleared up. A few days afterward the temperature again rose, again the urine contained large quantities of albumin and casts, and now for the first time the Widal reaction was independently obtained by both Drs. Park and Libman.

[4] A. Josias: "Fièvre typhoide à début péritonique," Méd. Moderne, 1905, No. 8.

[5] "Pharyngeal Diphtheria and Typhoid Fever," Amer. Med., June, 1901.

The grip type is another form of sudden onset and one which presents features of peculiar interest and gravity as regards the diagnosis. Let me cite a case. Eight years ago I was called to see a young man, 26 years of age, who for four days presented the group of symptoms: fever, general pain and aching, injection of the eyes and throat, bronchitis, etc., so characteristic of the catarrhal type of grip. The termination of the attack was as abrupt as its onset, and he immediately went off to a suburban club to recuperate. When I saw him before he left he was absolutely well. I was called to see him six days after and found him suffering from a fully developed attack of typhoid fever, to which he succumbed from perforation.

For a long time this case caused me much concern, for I was never sure whether I had not been guilty of an error in diagnosis in falsely considering his first attack to have been one of grip. Indeed, at a discussion on typhoid fever at the Metropolitan Medical Society five years ago, I referred to this patient and also called attention to the diagnostic difficulties offered by this class of cases, the exact relations of which I could not then understand. It was with no small amount of comfort that I read the last paper written by the late distinguished Parisian clinician, Potain.[6]

Potain discusses the occurrence of typhoid fever in direct succession to influenza and reports six cases of this character. In all these cases there was an abrupt onset characteristic of influenza, and they ran the course of influenza for a variable period. Then doubtful signs of typhoid fever developed, and the typical course of typhoid fever ensued with positive Widal reaction. Potain lays stress on the fact that the roseola appeared only after the eleventh to the thirty-first day had elapsed, and therefore infers that there could be no doubt of the existence of a preceding influenzal affection in these cases. His cases ran a mild course.

In the discussion of his paper[7] similar cases were reported. Le Gendre reported two cases of the same kind, one of them having been a physician who had been studying the pathologic anatomy of typhoid fever, and the other was a nurse who had been attending a case of typhoid fever. Widal, Vincent, Rendu and others presented similar observations. Wormser also calls attention to theses published by Millée[8] and Sabathier,[9] in which the sudden onset of typhoid presented phenomena which absolutely recalled the grip. Vernon[10] has also discussed the clinical association of grip and typhoid fever. The general consensus of French opinion is that the antecedent attack of grip has predisposed to the typhoid affection. With this view I am not absolutely in accord, since the subject can not be considered settled until further opportunity has been given to study the Widal reaction in the earlier attacks, nor should we lose sight of the fact that there are undoubted cases of typhoid fever, the onset of which is exactly the same as influenza.

The differential diagnosis of these two conditions, an influenza and some forms of early typhoid fever with abrupt onset with marked catarrhal symptoms and general muscular pains, is by no means easy. Some of the important characteristic diagnostic symptoms of typhoid may usher in an influenza. Thus in no other disease (except typhoid fever) is bradycardia so common as in grip. Furthermore, a moderate enlargement of the spleen is quite frequent in grip. Intestinal symptoms may also be present, while the general symptoms may be absolutely identical. The progress of the case, the roseola, the Widal reaction, etc., alone enable us to differentiate these cases.

How can these cases of sudden onset be explained? One explanation is that already given, viz., that the typhoid bacilli have developed silently in the organism and without presenting any marked clinical features until the disease was well developed. The early development of the Widal reaction, which has already been referred to, would seem to corroborate this view. In many cases, however, this explanation will not hold, and the explanation of the sudden onset must rather be found in the rapid development of the organism within the body. As an example of this I might mention the case of a physician in this city, who, while working with typhoid cultures, accidentally swallowed some of the bouillon mixture. Seven days after he was suddenly taken ill with high fever, marked prostration and diarrhea. Within two days a complete picture of typhoid was fully developed.

The rapid growth of the typhoid bacillus is favored either by a pre-existing infection, such as grip, tuberculosis, malaria, etc., which has debilitated the patient, or by other causes which have enfeebled the patient and lessened his power of resistance, and thus favored the rapid growth of the organism. I refer to the effects of severe physical exercise, as in soldiers or athletes, and the effect of severe mental strain, etc., since in many of these patients physical or mental strain has preceded an attack of typhoid fever. The future must alone decide which of these explanations is correct. Probably both are of importance.

Be the explanation what it may, the clinical fact remains that in about 10 per cent. of the cases of typhoid fever an abrupt onset is possible, the clinical manifestations of which are so varied and so uncharacteristic of the classic typhoid fever of gradual onset, that in any case of severe acute illness of sudden onset in which there is a disproportion between the severity of the symptoms of infection and the clinical findings, a properly applied test for the Widal reaction should never be omitted. The fact that the Widal reaction develops so early in the cases of typhoid fever with abrupt onset lends particular value to this test in these cases.

A CRITICAL STUDY OF THE VARIOUS METHODS EMPLOYED FOR ENUMERATING BLOOD PLATELETS.*

JOSEPH H. PRATT, M.D.
BOSTON.

The two chief characteristics of the blood platelets are their marked tendency to undergo speedy dissolution in shed blood and their property of adhering to one another and to foreign objects. These characteristics explain the difficulties that have been experienced in attempts to count accurately the number of platelets.

The early investigators used various preserving fluids in their attempts to prevent the disappearance of the

* This investigation was made with the aid of a grant from the Rockefeller Institute for Medical Research.

platelets from freshly drawn blood, and the counts were made with the ordinary hematocytometer. The results were regarded as so unsatisfactory by Halla[1] that he concluded from his study that it was impossible to determine the absolute number of blood platelets, and that the relative number could be estimated best in fresh preparations. Only a few years ago Türck[2] employed the same procedure, evidently because he regarded even the newer methods of counting the platelets as quite untrustworthy. The investigations of Eberth and Schimmelbusch[3] on the relation of the platelets to thrombosis strongly impressed them with the opinion that there were more platelets in the circulating blood than the counts indicated.

DESCRIPTION OF METHODS.

Havem,[4] with his students, used a variety of diluting and preserving solutions in his enumeration of blood platelets. One that he highly recommended was the amniotic fluid of the cow, to which tincture of iodin had been added. This was prepared according to a method devised by Max Schultze.[5] The dilution of the blood was made in the graduated capillary pipette, and the counting chamber was employed. Hayem[6] states that the average number of platelets in the blood of man is 250,000 per c.mm. Tables published by his pupil, Cadet,[7] showed that of 108 healthy individuals only two had a plate count below 200,000, and only four above 300,000. The highest count was 310,000.

Afanassiew[8] found that a weak peptone solution had advantages over the fluids previously employed. It preserved the erythrocytes as well as the platelets, and staining of the platelets was rendered possible by the addition of an anilin dye. The fluid was prepared by mixing 0.6 per cent. of dried peptone with a 0.6 per cent. solution of sodium chlorid; 1 to 10,000 or even 1 to 20,000 of methyl violet was added. The fluid was boiled and filtered; then preserved in sterile flasks. For the enumeration of the platelets the ordinary blood-counting apparatus was used. Afanassiew found that the number of platelets in healthy adult men varied usually from 200,000 to 300,000 per c.mm. In fourteen counts of his own blood using various preserving fluids, most commonly Pacini's fluid and osmic acid, the average number of plates was 231,000, the average number of erythrocytes was 5,278,000. In eight determinations made with the aid of peptone solution the average was 250,000 per c.mm. Tables published by his pupil, Cadet,[7]

Fusari[9] used the melangeur. He gave the number of plates as varying from 180,000 to 250,00 per c.mm. Muir[10] likewise used the graduated pipette. He pointed out that the blood should be quickly drawn into the tube, and the dilution made rapidly. He found 200,000 to 250,000 per c.cm. in normal individuals.

Kemp and Laker found independently that the use of the graduated pipette (melangeur potain) introduces an error, because many of the platelets adhere to the wall of the pipette, and hence the counts are too low. Laker found that counts of the same blood varied greatly. Both Laker and Kemp, and later Brodie and Russell, Determann and myself avoided the use of the pipette, and employed indirect methods for counting the platelets. The ratio of platelets to erythrocytes is determined in a drop of diluted blood, and then the number of erythrocytes being known, the number of plates can be easily calculated. Laker[11] ascertained the number of erythrocytes in the ordinary way; then he mixed a small drop of blood as quickly as possible with a large drop of fixing fluid. The mixture was made homogeneous by stirring and a portion of it was placed in the Thoma-Zeiss counting chamber and the number of erythrocytes and platelets within the same ruled areas in different parts of the chamber was determined. Kemp, without knowledge of the work of Laker, devised the same year a similar method. Van Emden,[12] employing Laker's method and using as a preserving fluid, 1 per cent. osmic acid, obtained in health counts of 200,000 and 300,000 platelets per c.mm.

Pizzini[13] used 1 per cent. osmic acid colored with methyl violet, and placed a drop of the fluid on the finger tip and pricked the skin through the drop. A portion of the diluted blood was at once placed in a Thoma-Zeiss counting chamber and the ratio of platelets to erythrocytes determined. It differs from van Emden's method chiefly in the fact that no attempt is made by stirring to distribute the platelets equally through all parts of the diluting fluid.

Prus[14] used the following modification of Flemming's solution:

Sol. acidi osmici, 1 per cent.	10
Sol. acidi chromici O, 1 per cent.	10
Acid. acetici glacial	1

The ordinary hematocytometer was employed. The erythrocytes were completely dissolved so that the plates were not obscured in the counting chamber by their presence, as was the case with other fixtures, unless the blood was greatly diluted. Larger quantities of blood could thus be examined, and this would lead to greater accuracy. In health he found as an average 500,000 platelets per c.mm.

Van Emden[12] used Prus's fluid. Before being used the pipette was cooled in a freezing mixture, as Hayem had shown that 0° C the platelets underwent less rapid destruction. He compared the method with that of Laker and found that the results agreed. Platelet counts of the blood of normal individuals yielded an average of 245,000 per c.mm.; the lowest was 208,000 and the highest 269,000.

Rabl[15] devised a method of counting the platelets in dried preparations. It involved the use of a complicated stain and the necessity of counting all the plates on the two cover-slips between which the drop of blood was spread.

Brodie and Russell used solutions of glycerin of various strength, colored and dahlia. Excellent results were obtained with a solution composed of equal parts of glycerin, saturated with dahlia, and 2 per cent. sodium chlorid. In solutions containing a high per cent. of glycerin the platelets are freely movable. Unfortunately, glycerin dissolves out the hemoglobin from the erythrocytes. They found, however, that an enumeration can be made before the fluid renders the erythrocytes invisible. They determined the ratio of platelets to erythrocytes. In a properly prepared specimen the platelets moved freely across the field of the microscope and were never clumped. A series of fields taken at random were counted until three or four hundred erythrocytes had been enumerated. The erythrocytes numbered on an average 5,400,000 per c.mm., and the platelets 635,000 per c.mm. They fail to state whether these figures are based on the examination of one or many individuals.

Determann[16] determined the ratio of platelets to erythrocytes in a counting chamber. He preferred as a preserving and diluting fluid a 0.9 per cent. solution of sodium chlorid, to which was added a drop (to 10 c.cm.) of a concentrated aqueous well-filtered solution of methyl violet. He tried a variety of other fluids, including a mixture composed of 1 per cent. sodium chlorid and 5 per cent. potassium bichromate, as recommended by Wlassow,[17] and also Hayem's, Pacini's and Müller's fluids, 1 per cent. osmic acid. In a study of twenty-five healthy individuals he found the ratio of platelets to erythrocytes varied from 1-18 to 1-30. The average was 1-22. Assuming the number of erythrocytes to have been 5,000,000 per c.mm., the average number of platelets was 227,000.

Kemp and Calhoun[18] used the indirect method of enumerating the platelets. The number of erythrocytes was estimated with the hematocrit, and the ratio of platelets to erythrocytes determined in a Thoma-Zeiss counting chamber. The preserving fluid was composed of formaldehyd, 40 per cent. solution 1 part, sodium chlorid 1 per cent. solution, 15 parts, with methyl green enough to color. The average number of platelets per c.mm. was found to be 862,000 for men and 833,000 for women. These figures were based on fourteen different counts of blood from eleven men and of six counts of specimens from two women. In another series[19] of determinations the average number of platelets per c.mm. taken from a mean of seventy-two observations on nineteen individuals was 778,000. The maximum was 961,500 and the minimum 730,000. In a later communication Kemp[20] stated that the average of five counts on five consecutive days on the same individual was 457,000 platelets per c.mm.

The most recent paper on the enumeration of platelets is that by Helber.[21] He used a 10 per cent. solution of sodium metaphosphate, which was first employed as a preserving fluid for platelets by the writer.[22] Helber had a special counting chamber constructed which was 0.02 mm. deep. In other respects it resembled the ordinary Thoma-Zeiss chamber of 0.1 mm. depth. A cover-slip 0.10 mm. thick (No. 16 in Zeiss' Catalogue for 1902) was used. The system of Zeiss lenses usually employed was objective E and compensation ocular 6. The graduated pipette designed for a dilution of 1-31 was carefully cleaned with sulphuric acid, water, alcohol and ether. Blood was drawn to the mark 1, then the melangeur was quickly filled with 10 per cent. sodium metaphosphate solution to the mark 31. The number of platelets was determined in the blood of twenty-four healthy men. The lowest count was 192,000, the highest 264,000; the average was 228,000. Four times the number was under 200,000, seven times between 200,000 and 220,000, eight times between 220,000 and 250,000, and five times above 250,000.

CRITICISM OF THE FOREGOING METHODS.

The results obtained vary considerably. Hayem gives the average number of platelets as 250,000 per c.mm.; Afanassiew, 200,000 to 300,000; Fusari, 180,000 to 250,000; Muir, 200,000 to 250,000; Brodie and Russell, 635,300; Prus, 500,000; van Emden, 245,000; Determann, 227,000; Kemp and Calhoun, 778,000; Helber, 228,000.

There are four main sources of error:

(1) *Fragments of erythrocytes (Arnold's bodies) have been mistaken for blood plates.* The platelets which Hayem described as containing hemoglobin were probably of this nature. Van Emden maintained that if the melanguer filled with a mixture of blood and Prus's fluid were shaken too vigorously artefacts of traumatic origin are formed from the red blood corpuscles. Van Emden thinks that Prus mistook these bodies for platelets and attributes his high count to this error.

(2) *The use of a graduated pipette.* The tendency of the platelets to adhere to glass has been overlooked or disregarded by many in selecting a method of counting platelets. The investigators who have taken account of this are Brodie and Russell, Laker, Determann, and Kemp and Calhoun. The counts of those who used the capillary pipette were always too low, as many platelets adhered to the walls of the tube. This error, as I have shown in my observations recorded later, may amount to 50 per cent. Halla, as early as 1883, pointed out that if blood is drawn into a capillary pipette clumps of platelets are formed. None of the methods can be regarded as trustworthy which involved the use of the pipette. Hence the platelet counts of Hayem, Cadet, Afanassiew, Fusari, Muir, Prus, van Emden and Helber can not be accepted.

(3) *The use of the ordinary counting chamber.* Halla[1] recognized that in this chamber foreign bodies might easily be mistaken for platelets. It should be remembered that the depth of fluid on the Thoma-Zeiss micrometer slide is 100 microns, which is about fifty times the diameter of the platelet. The erythrocytes quickly settle to the bottom of the drop, but the platelets tend to float in the upper layers of the fluid, and it is difficult not to miss some of them in the count. Helber has indicated clearly the unreliability of platelet counts made in the ordinary counting chamber. On account of the distance of the cover-slip from the ruled lines on the slides a high objective with its slight focal distance can not be used. But in order to distinguish platelets from the degeneration products of erythrocytes (Arnold's bodies) a high power is needed. Professor Krehl and I attempted to overcome these difficulties by using a specially constructed Zeiss counting chamber of half the regular depth (0.05 mm. instead of 0.1 mm.). Later, Helber in Krehl's clinic solved the difficulties by employing a counting chamber 0.02 mm. deep, and replacing the usual cover-slip by one only 0.1 mm. thick.

The investigators whose results may be questioned owing to their employment of the ordinary counting chamber are Laker, Pizzini, Determann, Kemp and Calhoun, as well as Hayem, Afanassiew, Fusari, Muir, Prus and van Emden, who, as I have shown, introduced an additional error into their counts by employing the graduated pipette.

(4) *The lack of satisfactory preserving fluids was the* [illegible] *of error in many of the methods.* Brodie and

Russell tested the solutions used by earlier investigators, and discarded all of them. None was found in which the platelets did not stick to one another or to the erythrocytes or to the *leucocytes or to the glass*. The solutions tested included Hayem's fluid, Pacini's fluid, Afanassiew's fluid, and formic aldehyd of different strengths. Some fixed the platelets well, but could not be used, as the platelets did not remain freely movable in them. This study of Brodie and Russell would lead to the rejection of the methods of Hayem, Afanassiew, Muir, Determann, Kemp and Calhoun.

THE WRITER'S METHOD OF COUNTING PLATELETS.

Deetjen,[23] in 1901, found that the ager containing *sodium metaphosphate* had the property of preserving blood platelets when a film of blood was spread on it. At Deetjen's suggestion, Professor Krehl and I tested a weak solution of sodium metaphosphate as a preserving fluid. We found that the platelets speedily disappeared. In a 10 per cent. water solution of sodium metaphosphate, however, both platelets and erythrocytes were well preserved. For the past two years I have employed the following solution which gives equally good results:

Sodium metaphosphate (Merck).........	2 grams.
Sodium chlorid	0.9 grams.
Distilled water	100 c.cm.

This solution keeps indefinitely unless molds or bacteria develop.

The number of erythrocytes is determined with the Thoma-Zeiss apparatus, and the ratio of platelets to erythrocytes in fresh preparations of the blood. The slides and cover-slips must be perfectly clean. Immediately before use it is well to test the cleanness of the glass by placing a drop of water on it; if the drop can not be spread out in a uniform thin layer the slide or cover-slip should be rejected.

Glassware is placed first in sulphuric acid, saturated with potassium bichromate, then washed in water and alcohol and placed in jars containing 95 per cent. alcohol, where they are kept until needed. They are then removed from the alcohol and wiped dry on a clean towel. I have found this procedure more reliable than the one I formerly advocated of heating the cleaned glass to 200 C. and storing in Petri dishes.

A few c.cm. of the sodium metaphosphate solution are poured into a watch-glass. The ear is cleaned with soap and water, alcohol and ether, and then stabbed deep enough to permit drops of blood to flow freely. A sterilized platinum loop, similar to those used in bacteriologic work, with a diameter of about 3 mm., should be filled with the preserving fluid, and the center of the loop is brought in contact with a fresh drop of blood on the ear. There should be three or more parts of fluid to one of blood. If desired, further dilution may be made on the slide. A portion of the mixture should without delay be covered with a cover-slip. The spread of blood should be so thin that the erythrocytes are well separated. It is not necessary to mix the blood and fluid intimately by long stirring, as without it the platelets and erythrocytes will be found evenly distributed in good specimens, and the platelets will not be clumped. Two preparations should always be made, and if the ratio of platelets to erythrocytes varies markedly in the two, *then new specimens should be prepared*. An oil immersion lens should be used in counting and a Leitz 3 ocular or its equivalent. A square diaphragm in the ocular facilitates counting. This can readily be made from thick paper or a card. It forms a simple substitute for Ehrlich's ocular. The platelets and erythrocytes are counted in fields taken at random in different parts of the specimen, until 250 to 500 erythrocytes in each of the two preparations have been seen.

COMPARATIVE COUNTS BY DIFFERENT METHODS.

It was thought desirable to test the various procedures by counting the platelets in the blood of the same individual by different methods.

Test 1.—March 7. Healthy man, aged 25. Erythrocytes, 5,552,000. Platelet count by Helber's method, using the original Helber-Zeiss apparatus, 330,000. This platelet count was kindly made for me by Dr. Cadwalder of the Pennsylvania Hospital.

Platelet Count.—By my method, 550,000. Dr. Cadwalder had previously made several counts, by Helber's method, of blood from this same individual and never obtained a higher figure than 350,000.

Additional tests have shown conclusively that even the momentary contact of the blood with the walls of the glass pipette in the method used by Helber destroys many platelets.

Test 2.—A leucocyte counter was cleaned and filled as Helber directs, *then a drop was expressed on a slide and the ratio* of platelets to erythrocytes determined.

Platelet Count.—By my method, 1,443,000; after the blood had been drawn into a pipette according to the method of Helber, 561,000. In both counts 10 per cent. sodium metaphosphate was the preserving fluid used.

Test 3.—June 7. Healthy man, aged 46. Erythrocytes, 5,480,000.

Platelet Counts.—Brodie-Russell method, 288,000; Kemp-Calhoun, 304,000; Determann, 498,000; my method, 668,000.

Determann specimen after standing one hour, 171,000 per cm.; my specimen after five hours, 637,000 per cm.

Test 4.—June 8. Woman, aged 32. Posthemorrhage anemia. Erythrocytes, 3,768,000.

Platelet Counts.—Determann, 410,000; Kemp-Calhoun, 488,000; von Emden, 508,000; *my method*, 1,142,000.

Test 5.—June 23. Erythrocytes, 4,304,000.

Platelet Counts.—My method, 1,196,000 per c.mm.; 1 per cent. osmic acid substituted for sodium metaphosphate solution, 130,000 per c.mm. The same proportions of blood and preserving fluids used in both determinations, the dilution being about 1 to 4.

PLATELET COUNTS IN NORMAL INDIVIDUALS BY MY METHOD.

	Sex and age.	Platelets. per c.mm.	Erythrocytes. per c.mm.	Leucocytes. per c.mm.

The maximum count in this series was 725,000 per c.mm.; the minimum 226,000, and the average 469,000.

DISCUSSION.

Dr. George T. Kemp, Champaign, Ill., said that, in addition to the paper under discussion, he had had the pleasure of listening to a paper by Dr. Pratt, read before the Johns Hopkins Medical Society, on the subject of the enumeration of blood platelets in different forms of anemia, and that he regarded such work as of great value. He looked forward to seeing important discoveries made in the near future by the study of blood platelets in disease—discoveries which would be of decided use in diagnosis and prognosis. The importance of hitting on a reliable method for enumerating the platelets is obvious. Dr. Kemp called attention to two criticisms which Dr. Pratt had made of the Kemp and Calhoun method, and said that neither of them would apply. The first was that formaldehyd could not be used as a fixative. This was based, as Dr. Pratt stated, on a quotation from Brodie and Russell. Dr. Kemp said that he was familiar with Brodie and Russell's work, and, as he recalled it, they did not have sodium chlorid in the aldehyd fluid they tried. The Kemp and Calhoun formula calls for this, and it is essential.

---

[23] Deetjen: Virchow's Archiv, 1901, clxiv, p. 239.

If the proper percentages of salt and aldehyd are present, and if the blood is taken into a drop of the fluid placed over the puncture to receive it the instant it emerges, the platelets do not clump and the reds do not lose their hemoglobin. Another precaution is to take a small drop of blood into a large drop of the fluid and to mix them instantly. A gentle stir or two is sufficient.

Regarding the second criticism—namely, that the Thoma-Zeiss counting-chamber could not be used because the platelets floated at the top and, therefore, could not be brought into focus with the red corpuscles and the lines—Dr. Kemp said that, while this might apply with fluids used by Dr. Pratt and by Helber, as stated by these observers, it did not apply when the Kemp and Calhoun fluid was used. He had not used the Pratt nor the Helber fluid, but the specific gravity of the Kemp and Calhoun fluid was such as to allow the platelets to settle to the bottom readily so that the platelets, the red corpuscles and the lines are easily in focus at the same time. In the Kemp and Calhoun experiments a thin cover-glass was always used. Arnold-bodies are not formed in the fluid employed, and, as a rule, a one-sixth objective enabled an experienced observer to decide whether a given body was a platelet. It sometimes happened, however, that it was desirable to use a higher power, and for that reason Dr. Kemp said he regarded the Helber chamber as a great improvement over the ordinary form. He stated, further, that several different kinds of ruled eye-pieces had been used, and the counting-chamber dispensed with altogether. The results were not different from those obtained with the Thoma-Zeiss instrument. In conclusion, Dr. Kemp said that some of the platelet-counts given by Dr. Pratt, running over a million to the cubic millimeter, were larger than he had ever seen, except at high altitudes. He did not wish to offer any unfavorable criticism of the Pratt method, however, because he had not yet tried it.

VARIATIONS IN THE RATIO OF DIAMETERS OF THE NORMAL CHEST AT DIFFERENT AGES.

THE FORM OF THE PHTHISICAL CHEST.*

W. A. BESSESEN, A.M., M.D.
CHICAGO.

INTRODUCTION.

It is proposed to give in concise form records on which may be based deductions of the changes in proportions of the chest, in its development from the fetal state to the adult form. Information will be offered to emphasize the special periods where development is particularly marked, as this study has been but slightly touched on. A general knowledge of the changes in the human chest is given in most of our standard anatomic works without, however, a grouped record on which the statements are based; and the material collected in late years by clinicians and physical examiners, can be very profitably supplemented by using a practical method of summarizing the observations. The study of the human chest is always one of much interest to the medical practitioner for the valuable deductions that may be obtained. The skill with which the diagnostician of the present day utilizes the chest conditions in their various aspects has reached a high degree of perfection.

The statistics here presented include measurements on 502 subjects to illustrate the normal chest. To these are added 54 tubercular cases, which were studied in order to aid in substantiating Woods Hutchinson's[1] conclusions of the form of the chest in phthisis and its significance, as he emphasized the importance of the subject and wishes to see more extended measurements made. Besides, data are given which were taken from dogs, rabbits and guinea-pigs, numbering 46 animals. These data illustrate the typical quadrupedal chest sufficiently for comparison with the human chest. And, finally, there is an additional group of measurements from 16 monkeys. Though the observations are not very extensive, still they are sufficient to furnish a basis for proper deductions with a fair degree of accuracy.

METHODS.

In all the chest measurements I used steel calipers which registered in centimeters and millimeters. By familiarity with the instrument, the touch is schooled to give every measurement a like degree of pressure in applying the tips. By practice in palpating the chest and sighting the planes, the diameters are evenly placed and regularity is secured in the system of data. Fuller data were taken on the adolescent and adult chests than on the fetus, infant and child.

The following is descriptive of the diameters of the chest and the three planes selected for the placing of all diameters except the first:

1. The length of the chest is measured from the middle of the clavicle to the junction of the tenth rib with its costal cartilage, using the left side exclusively. The length of the chest was taken on both the right and left sides in 54 adults, to determine what disparity there might be between the two. The right-handed man in practically every case gave a slightly longer right side, due apparently to the somewhat more elevated shoulder mass on that side, increasing the inclination of the right clavicle over that of the left.

Bony landmarks were chosen for this diameter, because of greater accuracy than the use of an imaginary line, passing down the chest from the clavicle to the margin of the ribs and just one inch outside the nipple. The position of the nipple is variable, always fallible for locating a diameter of the female chest; and even on the male the nipple may be above or below the fourth rib, over which it is generally considered to lie; and it may be more or less than an inch to the inner side of a line, drawn from the middle of the clavicle to the junction of the tenth rib with its costal cartilage.

The three planes, placed at different levels of the thorax, are sighted perpendicular to the long axis of the body. They are not quite parallel with each other, as can be readily conceived when the normal curvature of the trunk is considered.

2. The dorso-ventral diameter in the upper plane (clavicular) passes through the upper part of the manubrium at the interclavicular notch.

3 and 4. The dorso-ventral and the transverse diameters in the mid-plane (nipple) pass just below the junction of the fourth rib with its costal cartilage.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Hutchinson, Woods: Some Deformities of the Chest in the Light of Its Ancestry and Growth, The Journal A. M. A., vol. xxix, Sept. 11, 1897, p. 512. Also: Is the Consumptive Chest Flat? The Journal A. M. A., vol. xl, May 2, 1903, p. 1196.

Measurements for forced inspiration, forced expiration and repose are made for each of these diameters.

The purpose of locating the mid-plane by a bony landmark was to secure more accuracy in the observations, for as already indicated the location of the nipple is a variable one. The common use of the nipple line and the nipple plane in securing anthropometric data ought to be discarded for a more exact method and one which is easily followed by the physician. Vierordt speaks of the nipple as an uncertain point, but only suggests that the errors its use in placing lines leads to "should be corrected by cultivating the eye to recognize what is to be regarded as the average location."

5 and 6. The dorso-ventral and transverse diameters in the lower plane (ensiform) pass just above the junction of the seventh rib with its costal cartilage. The end of the ensiform cartilage can not always be felt; the cartilage may be curled inward, turned abruptly to one side or the other of the median line, and it may be long or short. The variability in position of the end of the ensiform makes it an uncertain landmark to aid in placing a body plane.

I would again emphasize the use of planes, sighted perpendicular to the long axis of the body and passing through fixed bony landmarks of the thorax, in which planes the important diameters of the chest should lie. For the three dorso-ventral diameters the mid-line ventrally, represented by the sternum, and the mid-line dorsally, i. e., the spine, serve for placing the tips of the calipers. For the transverse diameters, the mid-axillary lines are used to serve this purpose.

INDICES.

In the tables, indices have been formulated to aid in presenting more graphically the principal changes in the chest as they occur. Fourmentin[2] was the first to determine the thoracic index by using the formula of the craniologists:

$$\frac{\text{Transverse diameter} \times 100}{\text{Dorso-ventral diameter.}} = \text{index.}$$

Maurel[3] used this index a little later, and he was followed by other clinicians, who made numerous observations as regards the two diameters of the chest. In 1897 Hutchinson,[1] instead of using the index of Fourmentin, adopted the less cumbersome method of dividing the dorso-ventral diameter of the nipple plane by the transverse diameter. The tables contain both methods, with some slight modifications. Preference is given to the newer index, when comparing variations in the diameters at successive periods of time.

$$\underset{\text{(Hutchinson)}}{\text{Breadth index}} = \frac{\text{Mid-Dorso-ventral}}{\text{Mid-Transverse}} = \frac{D}{T}$$

$$\underset{\text{(Fourmentin)}}{\text{Breadth index}} = \frac{\text{Mid-Transverse}}{\text{Mid-Dorso-ventral}} = \frac{T}{D}$$

$$\underset{\text{(Hutchinson)}}{\text{Length index}} = \frac{\text{Mid-Transverse}}{\text{Length of chest}} = \frac{T}{L}$$

Referring to the indices of Hutchinson, the lower the index the *longer* and *wider*, respectively, the chest. According to the index of Fourmentin, the higher the index the wider the chest.

MEDIAN VALUES.

For convenience in recording the measurements taken, printed cards of convenient size were used. These cards not only facilitated collecting data, but also were of especial value when grouped for the purpose of finding median values. The style of card used for the observations taken on individuals above 12 years of age is shown herewith:

Date..............

The method used in summarizing the many measurements which have formed the material for the following tables is W. S. Hall's[4] method of handling anthropometric data, based on Quetelet's[5] median value. The median value may be defined as "that value which is so located in the whole series of observations of a single measurement, that there are as many below it as above it." In a small number of observations, one extreme is almost certain to overbalance the other extreme, therefore the Hall-Quetelet method is the more accurate and must be conceded to have more value than the average.

For explanation, let us take the diameter dorso-ventral manubrium, in twenty-nine young men, all aged 21 years. It varies from 13 cm. to 16.6 cm. As each measurement is in centimeters and millimeters, the cards are arranged in successively increasing values for this particular diameter. The fifteenth card will be the median diameter, which in this instance was 14 cm. To have sought the arithmetical average would have been a time-consuming method. By dividing this series of measurements just mentioned into ten groups with a difference of 0.4 cm., we get:

EXAMPLE 1.—DORSO-VENTRAL MANUBRIUM DIAMETER OF 29 MEN.

Measurement..	13+	13.4+	13.8+	14.2+	14.6+	15+	15.4+	15.8+	16.2+	16.6+
Number of observations,...	8	1	7	7	3	0	2	0	0	1

If it is desired to substitute the established mathematical formula[4] for securing the median value, it can be readily done:

$$M = a + \frac{d\,(n/2 - l)}{m}$$

M = median value to be determined.
a = minimum value of median group (the group containing the median value).
d = difference between groups.
n = total number of observations.
l = sum of observations below the median group.
m = number of observations in the median group. Substituting:

$$M = 13.8 + \frac{0.4\,(29/2 - 9)}{7} = 14.08$$

---

[5] Quetelet: Anthropometric ou Mésure dés Different Facultés de l'homme, Bruxelles, 1870.

The median value is not only of more consequence in summarizing anthropometric data than the arithmetical mean or average, but it is based on biologic and mathematical laws.

Breadth, T/D.	0.77	0.86	0.90	0.95	0.95

The diameters of the lower plane were selected in securing the breadth indices of the animals and fetuses, because for them the greatest depth and breadth of the chest are in this plane. Even for several months after birth, the human chest normally presents its greatest dorso-ventral and transverse diameters in the lower plane. After this time the mid-plane diameters are equivalent to or slightly greater than the diameters of the lower plane.

The mid-plane is the most important one for study of the human chest, and the diameters of this plane will be used as before described in determining breadth indices from birth to maturity. The mid-transverse with the length of the chest T/L will give the length index.

TABLE 2.—DATA FROM FORTY-EIGHT BABIES.

Classification.	1 Under 3 days. (Included in col. 2.)	2 Under 26 days.	3 1 mo. to 13 mos.
Number measured	8	25	23

* The small figures indicate when all were not included. This also applies to tables 4 and 5.

ANALYSIS OF DATA.

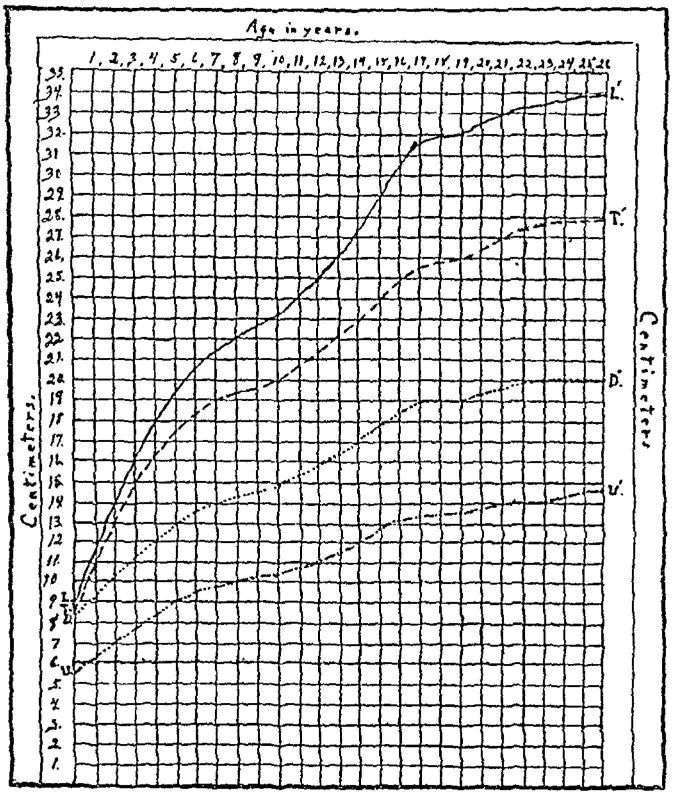
The typical quadrupedal chest with a dorso-ventral diameter distinctly in excess of the transverse, is necessitated by the backward and forward swinging of the fore limbs. This chest may be designated the deep or dorso-ventral type, represented by an index in excess of 1. See example 2.

Example 2.—The quadrupedal chest. Dogs (29 observations). Diameter dorso-vent., D, 15.2 cm.; Transverse, T, 11.7 cm.: Breadth index, D/T; 1.3. See Table 1, column 1.

The dorso-ventral type of chest is much less marked in the monkey, correlated with a frequently assumed upright position.

Example 3.—Monkeys (16 observations). D, 8.95 cm.; T, 8.55 cm.; D/T, 1.04. See Table 1, column 4.

In some of the anthropoid apes, measurements have shown a chest in which the transverse diameter is slightly in excess of the dorso-ventral. This chest may be designated the transitional type and represented as 1. (See Ex. 3.) With the change in position of the shoulder masses to the lateral aspects of the chest, and with the shifting of the scapulæ to the dorsal surface of the thorax, we see the transverse type of chest become more marked. In this type the index is less than 1.



Set of curves for graphic illustration of the course in development of the normal male chest from birth to maturity. The diameters at time of birth are: Length of chest, L=8.9; mid transverse, T=8.6; mid dorso-ventral, D=8.35; upper dorso vent., V=5.5.

The normal adult chest, with a marked increase in the transverse diameter of the mid-plane in excess of the dorso-ventral diameter of the same plane, is the type of vigor for man.

Example 4.—The normal adult chest, representing the transverse type. Men (25 observations). Mid-dorso-vent., D. 20 cm.; Mid-transvere, T 27.6 cm.; Index, D/T, 0.72. See Table 3, column 10.

We notice that in the fetus a breadth index is obtained equal to the breadth index of the anthropoidean mammal.

Example 5.—Fetuses 23. D/T = 1.018. Table 1, column 5. Monkeys, 16. D/T = 1.04. Table 1, column 4.

The full-term babe has a rounded, short chest with a slight predominance of the early transverse type.

Example 6.—Twenty-five babies; age 9 days. D, 8.6 cm.; T, 9 cm.; D/T, 0.95. Table 2, column 2.

During the first six years of child life the conspicuous feature in the development of the chest, relatively speaking, is the change in the transverse diameter, which has markedly increased. At no time before or after this period is there an equal degree of rapid change in any diameter.

Example 7.—Length and Breadth Indices Compared.

Indices	T/L	D/T	
Babies, age 2 days. (8 observations)	0.96	0.97	Table 2, col. 1
Boys, age 6. yrs. (30 observations)	0.88	0.75	Table 3, col. 1
Girls, age 7. yrs. (20 observations)	0.90	0.75	Table 4, col. 1

Having in mind the previous statement that the lower the index the longer and wider, respectively, the chest, then the change in chest diameters necessary to have brought about this drop in the breadth index over the drop in the length index, can be interpreted in no other way than the relative widening of the breadth beyond any other change. The chest has also elongated rapidly during the early years, and from the sixth year on for several years there is a gradual increase of both length and breadth, but the length develops somewhat faster than the breadth. At puberty the length of the chest takes on an active increase in growth over every other diameter, particularly in the male.

Example 8.—Influence of Puberty on Indices.

Indices	T/L	D/T	
Boys, age 12 yrs. (36 observations)	0.86	0.73	Table 3, col. 3
Boys, age 16 yrs. (23 observations)	0.81	0.72	Table 3, col. 6

By the twenty-fifth year the chest has reached its full length, and the transverse diameter which has been increasing gradually since the sixth year, and the dorso-ventral which has been deepening gradually since birth, are also now complete. In the male chest, from the twentieth to the twenty-fifth year, there is an apparent widening slightly in excess, relatively, over the increase in length, inferred from the increased length index.

The adult female chest does not reach so great a relative length as does the male chest.

Example 9.—Indices of Men and Women Compared.

Indices	T/L	D/T	
Women age 22 yrs. (21 observations)	0.84	0.72	Table 4, col. 5
Men, age 23 yrs. (25 observations)	0.83	0.72	Table 3, col. 10

By mensuration we not only learn (1) the shape and size, but also (2) the movements, and (3) the capacity of the chest.

The difference in the diameters of the chest in the mid-plane in ordinary and deep inspiration is an important factor in estimating the freedom and fullness of respiration. E. O. Otis[6] has emphasized the importance of this study in his measurements of the chest and lung capacity. Comparing normal and phthisical chests, the deficiency of expansion in the latter is first noticed.

---

[6] Otis, E. O.: Measurements of the Chest and Lung Capacity, International Med. Mag., vol. iii, pp. 85.

Example 10.—Chest Expansion.

	The Normal Chest.		The Phthisical Chest. (Very early cases.)	
	29 Boys, Age 19.	29 Women, Age 27.	5 Boys, Age 19.	6 Women, Age 31.
Diameter mid-dorso-vent.				
Forced inspiration . . .	21	19.5	19.6	18.3
Forced expiration. . . .	17	16 5	17.6	16.3
Repose	19	18.	18.55	17.7
	Table 3, col. 8.	Table 4, col. 6.	Table 5, col. 1.	Table 5, col. 4.

Such a deficiency indicates the presence of a local morbid process, notably tuberculosis. Rigidity of the chest as the concomitant of pulmonary tuberculosis has been pointed out by the clinician Fothergill. In the tubercular chest the length index is less than normal, the breadth index is greater than normal.

Example 11,—The Normal and Phthisical Chests Compared.

	Age.	Length of Chest.	Dorso-ventral. Upper Plane.	Dorso-ventral. Mid-plane.	Mid-T.	Indices.	
						T/L	D/T
100 men, normal.	26	33 05	14.	19.6	27.1	0.82	0.72
21 men, early pul. tbc. . . .	27	33.17	13.9	19.05	25.6	0.77	0.742
29 women, normal	27	30.	12.5	18.	25	0.84	0.72
6 women, early pul. tbc. . . .	31	29.65	12.5	17.17	22.82	0.769	0.752

The indices alone may not readily convey the changed formation accounting for this deviation; but by noticing the median values above, it is plainly evident that the transverse diameter has failed to keep pace with the increase in the dorso-ventral diameter, and with the lengthening of the chest during and after puberty. There is an arrest in development in the usual transverse widening, which makes the tubercular chest immature. The phthisical chest is not the so-called flat chest, as the projecting scapulæ may often make it appear, but it is a narrow chest tending to the rounded form with a relative elongation.

"Broad chests have a greater expansion than deep chests"; also "broad chests have a greater capacity (volume expansion) than do deep chests."[7] The broad chest, with its attendant increased expansion and increased capacity, should offer the best resistance to the tubercle bacillus; and it is generally conceded that persons with deficient expansion are more prone to develop tuberculosis. Furthermore, a failure in the normal development most likely leads to a decreased resistance.

There being such a predilection to tuberculosis, outdoor life, climbing exercises, etc., are especially indicated to prevent pulmonary infection. An active outdoor life encourages deeper and fuller respiration, which will gradually bring about an increased chest expansion. Climbing exercises, rowing, etc., are most important means of strengthening the shoulder muscles, so that the scapulæ will be drawn back on the dorsal surface of the chest. This more favorable position, together with the increased action of all the chest muscles, will be of the greatest influence in bringing about a widening of the chest, and thus correct the static condition.

SUMMARY.

1. The method of using fixed bony landmarks for the placing of chest diameters is accurate and readily applied.
2. The use of median values for evaluating anthropometric data saves time and the results derived from this method of evaluation are more accurate than the arithmetical average.
3. Important features in the shape of the chest, as well as in the movement and the capacity, may be appreciated by an observation of its principal diameters.
4. The human chest, in the course of its development, has passed through various stages from the deep or dorso-ventral to the broad or transverse type.
5. In the fetus and young babe, the lower plane gives a greater depth and breadth than the mid-plane.
6. The fetus under 30 centimeters in length presents a dorso-ventral type of chest—it is deep chested.
7. The newborn child represents the transitional type of chest—it is round chested.
8. During the first five years of life the most conspicuous change is the rapid widening of the chest in its transverse diameter—it becomes broad chested.
9. At puberty the length of the chest takes on an active increase in growth over the other diameters—the adolescent becomes long chested.
10. From the eighteenth to the twenty-fifth year the development of the chest is fairly uniform in all its dimensions and represents the highest development—the broad long chest.
11. The dorso-ventral diameter increases at an even rate from birth to maturity.
12. The phthisical chest of adult years, in general, shows an arrest in development of the transverse diameter following puberty.
13. The phthisical chest is a narrow one, tending to the rounded form, with a relative elongation.

DISCUSSION.

Dr. Woods Hutchinson, *Redlands, Cal.*, expressed his gratification that Dr. Bessesen's independent study corroborated, in the main, the views submitted in Dr. Hutchinson's essay. Since his attention was first directed to this question by some measurements which he made of tuberculous chests, nine years ago, a number of additional data have been collected, some by himself, but more by observers on both sides of the Atlantic whose interest was aroused by the publication of Dr. Hutchinson's results in the *British Medical Journal* in 1900. These measurements now number some 700 and support with singular closeness and unanimity substantially the same conclusions which his first series of 40 measurements did—that is, that the tuberculous chest is not flat, as at first glance it appears and as most text-books yet describe it, but round, and, instead of its antero-posterior diameter being diminished, this is normal or slightly increased, while the shrinkage has occurred in the transverse diameter.

Dr. Hutchinson's first measurements indicated a normal index of about 72, but he has since succeeded in accumulating a series of tables of nearly 5,000 measurements of normal individuals, chiefly soldiers in garrisons and college students and athletes in gymnasia, and on this mass the average index is slightly lowered—namely, 70 (69.9). The measurements of the 650 consumptive chests show an average index of 78, and, with the exception of one markedly aberrant series, the other 10 averages range within one point of 80, either above or below, thus making the consumptive chest 10° rounder than the normal. As these 650 measurements have been taken in three different London hospitals, in New York, in Chicago, in Leeds, England, in Portland, Oregon, in San Francisco, and in Memphis, Tenn., they may be regarded as fairly well establishing a probable average in this disease. This shape of chest is, of course, the persistence of the child chest and represents an arrested development at about the proportions, normal in the twelfth to the fifteenth year. As Dr. Bessesen has again shown, this represents an evolution from the ancestral quadrupedal chest, which in all animals outside of the human species, except the anthropoids, some of the bats and some of the whales, is much deeper than it is wide. A similar form of chest has also been found by Drs. Evans and Hugh, of Chicago, among the paupers in Cook County Hospital, and by Arthur McGugan among the chronic insane, thus making it probable that it is the type of chest associated with arrested and imperfect development, or, as we loosely term it, degeneracy. Of this series of cases, some 70 were measured in a very early stage of the disease, and these show an index within one point of as high as the rest of the series, thus making it highly probable that this type of chest precedes the disease, although it is probably exaggerated by the increased respiratory effort and interference with proper emptying of the lungs due to the lesions of the disease. Another straw pointing in the same direction is the fact that of 31 successive cases of phthisis in his own practice, the 16 cases who did badly, 6 of them dying, presented an average index of 80.2, while the 15 who did well, 4 of them making complete apparent recovery, showed an average index of 74.6. As only 15 per cent. of the cases of tuberculosis measured failed to show a higher index than the normal, it would thus appear as if the measurements of the chest would furnish a datum of considerable value in the diagnosis of tuberculosis, and that any child or young adult presenting a higher chest index than normal, for his age, ought to be given a vigorous open-air life, with abundance of nutritious food, and every measure taken which would promote normal development and the attainment of full vigor. The round infantile chest and the small pubertal heart make the *habitus phthisicalis.* An exaggeration of this type of chest, due to the lateral pull of the diaphragm, gives rise to the pigeon breast or rachitis and adenoids.

MYOMA OF THE ESOPHAGUS.*

JOHN BRYANT, JR.
Second Year Class, Harvard University Medical School.
BOSTON, MASS.

Though myoma of the esophagus probably is not very rare, comparatively few cases have found their way into medical literature. That it is not common is shown by the fact that in the large number of autopsies recorded during the past five years at the Boston City Hospital, the Long Island Hospital and the Harvard Medical School, but two cases of myoma of the esophagus occur. On this account, it seems advisable to publish reports of these two cases and briefly to review those previously reported.

Case 1.—A. J., male, aged 60, was admitted to the Long Island Hospital Nov. 22, 1902, in a moribund condition. Physical examination showed extreme cyanosis, edema of lower extremities, weak irregular heart sounds, and dullness with diminished breath sounds over both backs. The patient failed to respond to treatment and died at 2:35 a. m. November 23.

Autopsy.—November 26, by Dr. G. B. Magrath. L. I. H. 02.112.

Anatomic Diagnoses: Deformity of thorax; edema of legs and scrotum; chronic adhesive pleuritis; hydrothorax; hydropericardium; hypertrophy and dilatation of right ventricle; emphysema and edema of lungs; chronic passive congestion of spleen, intestines, liver and kidneys; ascites; leiomyoma of esophagus; general arteriosclerosis.

Digestive Tract: The stomach on its outer aspect at a point near its junction with the esophagus and above the lesser curvature presented a mass of the size of a horse chestnut, which on dissection was found to be continuous with the wall of the esophagus and showed a fleshy, somewhat striated, cut surface. (Changes in the other viscera were as indicated in the anatomic diagnoses.)

Case 2.—A. D., female, aged 62, was admitted for senile insanity to the Boston Insane Hospital three times during the five years beginning Aug. 22, 1900. On the last admission she complained of stomach trouble and ate little, presumably on account of delusions of poisoning. In the hospital she complained a good deal of pain in her abdomen. Ten days before her death, which occurred Jan. 27, 1905, she had an attack of nausea, and vomiting, which was persistent and continued until death. During the last twenty-four hours there was a slight showing of dark blood in the vomitus; otherwise none at any time.

Autopsy.—January 28, by Dr. E. E. Southard, N. 05.29.

Anatomic Diagnoses: Stricture of esophagus from pressure by leiomyoma; tumor (leiomyoma) nodules at cardiac orifice and on fundus of stomach; ulcer at cardiac opening of stomach; small healed ulcer of fundus of stomach; emphysema of lungs; edema of pia mater; chronic diffuse nephritis; biliary calculi; chronic tuberculosis of both apices of lungs; calcified thrombi in splenic artery; submucous polyp of uterus; chronic localized peritonitis.

Digestive Tract: The esophagus measured 7 cm. at a level 12 cm. above the cardia, 3 cm. at level, 9 cm. above cardia and widened to 6 cm. at level, 7cm. above the cardia. Opposite, to the right of and behind, the stricture (the middle point of which was about 14 cm. below pharynx) was a dense ovoidal mass (Fig. 1), measuring 3.2 by 3 by 2.5 cm., smooth, loosely encapsulated, mottled gray-pink externally, cutting like a uterine fibroid, with a gray section surface which was coarsely fasciculated and varied a little in translucence, according to direction of bands. There was no invasion of surrounding structures by the mass. The mucosa of the whole esophagus was evenly reddened.

Just above the cardia, which measured 6 cm., was a flattened, bean-shaped mass, 1.4 by 0.7 by 0.5 cm., inclosed between the mucosa and the outer wall of the esophagus, set transversely to the axis of the esophagus on the right side. Opposite this mass was a shallow ulcer, 1.5 by 0.7 cm., with smoothly curving, reddened, slightly raised border and a clean base.

The stomach wall, in the main, was well injected and normal. The stomach measured 25 cm. from cardia to pylorus and 19 cm. in the greater circumference. There was a subperitoneal nodule measuring 1 by 0.8 by 0.7 cm., in the anterior wall of the fundus 8 cm. below the cardia. A smooth, dimpled scar, not over 0.5 cm. in diameter, united the normal-looking peritoneum and mucosa about midway of the anterior surface of the fundus. (Changes in the other viscera were as indicated in the anatomic diagnoses.)

Microscopic examination of the tumors in these cases showed the usual structure of leiomyomata. Bundles of smooth muscle cells ran in various directions to interlace with each other. With these there was a moderate amount of fibrous tissue best shown by Mallory's anilin blue connective tissue stain.[1]

There was no evidence of rapid growth or malignancy. Sections from Case 2 stained by the phosphotungstic-acid-hematoxylin method show fairly well-preserved myoglia fibrils, further indicating the smooth muscle character of the tumor.

In Case 1 there were no symptoms referable to the myoma, and the autopsy showed no signs of obstruction to the esophagus. In Case 2 there were symptoms, at least late in life, of obstruction of the esophagus, and at autopsy this was borne out by the moderate dilatation of the esophagus above the tumor. In Case 1 there was a single tumor, while in Case 2 there were multiple tumors. In both, the tumors appear to have developed in the outer coat of the esophagus. Both patients were old people.

In the literature it has been possible to find nine cases of leiomyoma of the esophagus as follows:

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

* From the Sears Laboratory of Pathology, Harvard University Medical School.

[1] All staining methods used are to be found in Mallory and Wright's Pathologic Technic, 3d edition.

Eberth[2] reported the case of a patient, aged 50, with no symptoms during life referable to the tumor of the esophagus. At autopsy a leiomyoma was found situated at the lower end of esophagus, touching the cardiac end of the stomach and measuring 9.1x11.9x3.5 cm. The tumor half surrounded a dilated esophagus, and consisted of bean-sized nodules bound together by connective tissue.

Coats[3] reported a case of a man, aged 61, with symptoms of obstruction and death from inanition. At autopsy a pedunculated tumor was found attached 6¾ inches below the glottis and extending to the cardiac orifice of the stomach. The tumor measured 4¾x2x1 inch. The esophagus was much dilated. The tumor was made up of spindle cells and a small amount of connective tissue.

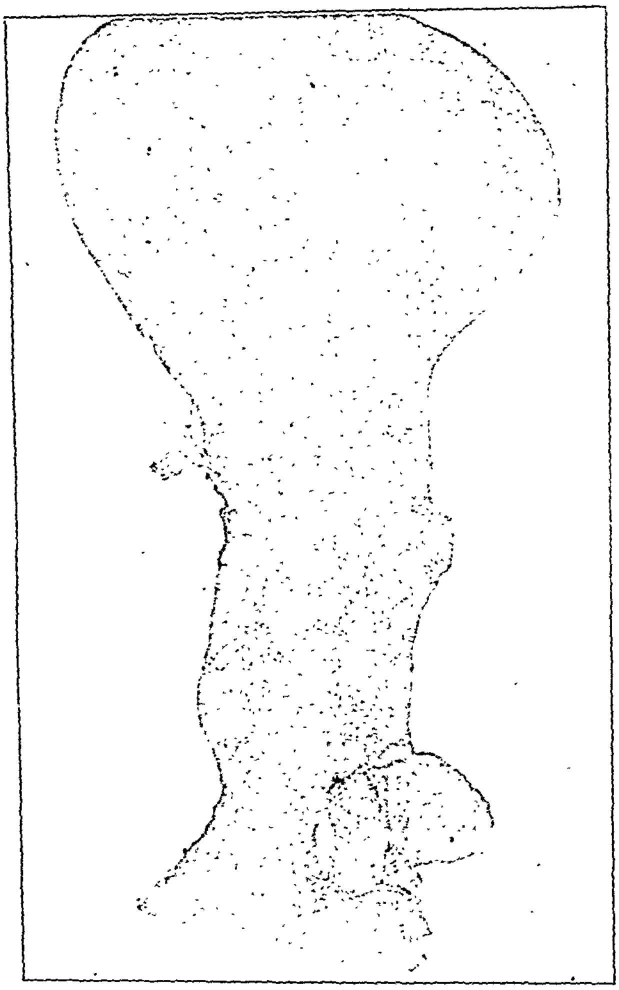

Fig. 1.—Myoma of esophagus from Case 2.

Fagge's[4] patient was a man, aged 37, with no symptoms during life. At autopsy an egg-shaped tumor 2x1¼x1 inch was found just below the level of bifurcation of the trachea. Microscopic examination showed a smooth muscle structure.

Meyer's[5] patient was a woman, aged 78. There were no symptoms during life. At autopsy a tumor was found in the upper part of the esophagus beginning at the level of the thyroid. The tumor measured 8x4x2.5 cm. Microscopically, it was composed of smooth muscle.

Illig's[6] patient showed no symptoms during life. At autopsy a tumor was found at the level of the bifurcation of the trachea, almost surrounding the esophagus and measuring 5x5.5x2 cm. Histologically, it was composed of smooth muscle.

Pichler[7] reports the case of a man, aged 50, in whom there were no symptoms during life. A tumor was found 11 cm. below the arytenoid cartilage, composed of a mass of nine nodules, each from 2 to 17 mm. in diameter, bound together by connective tissue. Below these there were five scattered nodules.

Virchow[8] reports a case in which there was a myoma in the lower part of the esophagus, measuring 5 lines in diameter.

Förster[9] and Trastour[10] reported cases, but the details are not accessible.

This makes eleven cases of myoma of the esophagus. In seven the age is stated, and of these six patients were 50 or over; the others were 37. In six the sex is given, four were male and two female. In only two were there symptoms of obstruction. Of nine in which the situation is mentioned, only one occurred in the upper one-third of the esophagus, the others were in the lower third. In two patients there were multiple separate tumors.

In conclusion, I wish to express my thanks to Dr. H. A. Christian for suggesting this study and for assistance in its completion, and to Drs. S. W. Crittenden, G. B. Magrath and E. E. Southard for notes on the cases.

REPORT OF COMMITTEE ON PROPRIETARY MEDICINES.*

O. T. OSBORNE, M.D.
NEW HAVEN, CONN.

AND

C. S. N. HALLBERG, Ph.G., M.D.
CHICAGO.

In the report of this committee made last year, the fundamental principles which should govern physicians in the employment of proprietary medicines were presented, and their adoption by the section was the first concrete result from several years of speculation. The enunciation of these principles, no doubt largely aided, if they did not influence, the Board of Trustees of the A. M. A., which, through the Secretary, the Editor of The Journal, authorized the organization of the Council on Pharmacy and Chemistry for the purpose of taking up this question in a practical manner.

During the five months the Council has been at work, many phases of the proprietary-medicine question have come up for consideration, but the one which to our mind is the most important, and which it is thought most apropriate to bring before the Section is that of the nomenclature of this class of medicines.

In order intelligently to discuss the subject, it is desirable briefly to enumerate the different kinds of names and the methods of naming medicinal articles, together with such legal considerations as these involve.

SCIENTIFIC OR DESCRIPTIVE NAMES.

The necessity for naming substances used in medicine according to a systematic plan is as essential in this as in any other branch of medical science.

The natural history sciences, botany, zoology and mineralogy, and chemistry, physics and pharmacy, all contribute to the vast number of substances used in the prevention, treatment and cure of disease. All of these sciences have their respective nomenclatures, which are an integral part of each; in fact, so much so that it is said that a superficial knowledge of these branches is often acquired simply by mastering the terminology. It is self-evident that no study of the sciences can be satisfactorily pursued without the terminology; it is the language, the expression of which gives to each substance or subject its identity, character and meaning, and affords methods of differentiation and distinction.

These terms are derived from the dead languages, chiefly because of their stability, their flexibility, and because being learned through the classics are familiar to all, and, therefore, are in a degree the universal languages.

While these facts are of such common knowledge that their mention should carry an apology, they are constantly ignored and their privileges violated in the naming of medicines.

While names must be formed to designate new substances or to indicate newly discovered facts and subjects, in the case of medicinal substances, the names should at least have the origin or derivation for their basis.

While the early generic names of plants were chosen rather arbitrarily, the differentiation of their species as a rule is indicated in their specific names. The confusion of some vernacular plant names is too great to be tolerated, as, for example, cocoa (cacao), coco (nut) and coca, three as distinctively different plant substances as could be imagined. While Alexander von Humboldt, when he discovered the chocolate nut named it theobroma (God's drink), and cacao, after the native Indian name, it has always been confused with the cocos nucifera, the milk-bearing cocoanut; and the oil of theobroma is to-day called cocoa-butter, instead of cacao; while coca, the leaves of erythroxylon coca, whence cocain is obtained, is designated officially as erythroxylon.

The vernacular names of plants are so unreliable as to prohibit their use in medicine; sometimes similar names are applied to entirely different plants in different locations. There are, for example, ever so many different snake roots, viz., black, Canada, senega, Virginia, white, etc. Who could be certain of their identity unless they could be designated, respectively, cimicifuga, asarum, senega, serpentaria, etc.? No physician could safely order of these drugs without using the Latin name, or, in the case of official drugs, the Anglicized Latin titles.

In the same way, the principles of plants are named after the Latin name, usually the generic name, in the case of alkaloids, glucosides or neutral principles, and when a second one is discovered it is usually named after the specific name, such as pilocarpin and jaborin from *Pilocarpus jaborandi.* There are some exceptions to this, as, for example, morphin, named by Serturner for "the God of Sleep," it being the first alkaloid discovered. One hundred years ago no system of nomenclature for these principles had been evolved.

CHEMICAL NOMENCLATURE.

With chemical substances it may, indeed, be said that the nomenclature is the fundamental part of their knowledge. While the elements have been more or less arbitrarily named, yet there is a significance or meaning in the name of every element, devised by its discoverer from some physical or chemical property. Before the chemical terminology now *en vogue,* devised by Berzelius, the exact relation and distinction of chemical compounds was not clear, but with a better conception of chemical facts and theories a nomenclature was devised which made possible the systematic study of chemistry, and subsequently by the type theory of Dumas disclosed the infinite relations of the organic compounds. To study chemistry without understanding the nomenclature, would be as absurd as to attempt to study the human body without being familiar with anatomy. To name chemical substances without designating them in chemical terms is not only unscientific, but often misleading. No physician can safely order any chemical substance without the possibility of error, except in correct chemical terms; besides, he loses the great advantage in the use of chemical terms indicating the chemical properties, and consequently often their chemical reactions and even their therapeutic virtues.

While this should always be the aim in naming inorganic compounds, as well as many organic salts, it is not always practicable with that extensive and constantly growing list of chemicals commonly called synthetic. Owing to the complexity of the molecules of many of these, the complete chemical names can not always be used and the manufacturers employ a contracted name, or substitute a more or less arbitrarily selected title, which is also usually registered as the trade-mark of the article. The new United States Pharmacopeia furnishes several illustrations of such titles having been formed by the contraction of the chemical names: Acetphenetidinum for acet para phenetidine or phenacetin. Benzosulphinidum for benzoyl sulphonicimide or saccharin. Hexamethylenamine for hexamethylentetramine or urotropin. Methylthionina for tetramethyl-thionine or methylene blue. Sulphonethylmethanum for diethyl sulphone methylethylmethane or trional. Sulphonmethanum for diethyl sulphone dimethylmethane or sulfonal.

The deletion of the Greek numbers and adjectives in these titles does not impair their value, at least for the purposes of medicine and pharmacy, and though somewhat unwieldy, yet they certainly should be given the preference over coined and arbitrary titles, especially since these are usually protected by registration as trademark or by copyright.

PHARMACEUTICAL NOMENCLATURE.

There remains now for consideration only the nomenclature of the special forms required for the administration or therapeutic application of these drugs or natural substances of organic origin, and their various principles and educts and the chemical products. This is distinctively pharmaceutical, that is, their preparation, compounding and dispensing constitute pharmacy. Since the time that Galen first prepared the plant extracts, from the *elixir proprietatis* of Paracelsus to the latest form of elegant medicinal tablet or bon-bon of *"fin de siecle"* pharmaceutic art, a nomenclature has been evolved which is, perhaps, as well established and comprehensive for pharmacy as that of any other science or profession. The nomenclature of pharmaceutical preparations, moreover, is given an advantage and prestige enjoyed by scarcely any other science, in that it has legal standing in every country through their pharmacopeias.

The pharmacopeias, as is well known, are the legal authority for medicines in their respective countries, which gives to the nomenclature a significance and meaning scarcely realized. There are in the United States Pharmacopeia over thirty different classes of preparations and extra-officially nearly as many more modifications of these official preparations. Yet, the question may well be asked, Have these pharmaceutical terms a purpose? If so, why are they constantly ignored? Manufacturers either ignore them or vie with each other in coining new names to substitute for them. The pharmaceutical nomenclature keeps step with therapeutic science; as soon as a new name for a new form of preparation is required, the pharmaceutical literature quickly responds and the name appears. It is safely asserted that there is not a single medicinal preparation now offered to the medical profession which could not be classified under the present nomenclature. Is it because the terms, tincture, liquor, elixir, syrup, spirit, fluid extract, pill, powder or ointment, are too simple, too commonplace, or hackneyed, and have lost their charm, or is it that the manufacturers seek to evade them in order better to be able to palm off some of these classes of preparations under mysterious and captivating titles, possibly a cloak for some old-time mixture of doubtful composition and questionable therapeutic virtues?

It is recommended that every medicinal article have a scientific title or descriptive name, and that the exclusive control of an article through registration of the name as a trade-mark or through copyright, be regarded as a perversion of the purpose and function of the patent laws. The greatest manufacturers, those who have attained the greatest reputation, prestige and patronage of the medical profession, even to-day, are those who rely on their names as the criterion for the quality of their products. What trade-name product has ever enjoyed the reputation of Powers & Weightman's quinin, Rosengarten hypophosphites, Mallinckrodt's potassium iodid, Squibb's chloroform, Parke Davis & Co.'s fluid extracts, Wyeth's elixirs, etc.? Manufacturers are short-sighted to ape the methods of the anonymous and pseudochemical companies in employing trade names, thus losing the prestige their names would confer on any other products they may introduce from time to time.

ACUTE HEMORRHAGIC PANCREATITIS.*

C. F. NEW, M.D.
Pathologist Central Hospital for the Insane.
INDIANAPOLIS.

In the following case the woman was a patient at this institution under the care of Dr. Stockton, who makes the following clinical report:

Patient.—The woman, aged 55, was admitted to the institution ten years ago. She had delusions of persecution, hallucinations of sight and hearing and was restless, sleepless, dull and melancholy.

History.—Little is known regarding her life and condition previous to admission, but from what could be gathered from herself and from the commitment papers the indications are that she had led a dissolute, immoral life and that she was addicted to the use of morphia. From the time of her admission until the onset of her illness her physical health was good except for a moderate constipation which required the use of a mild purgative from time to time. Mentally there were no marked alterations, but she manifested some retardation of thought and occasional periods of irritability and quarrelsomeness, with obscene and immoral talk. On arising on the morning of March 14, 1904, she complained of feeling ill and suffered from nausea and vomiting, but was up and about until 11 a. m., when she began to complain of great pain and distress in the region of the stomach, aggravated when lying on the back, and of more or less tenderness on examination. The severity of the pain was such that an opiate was necessary to relieve it. At 6 p. m. the temperature was 102.6 and pulse 130, with but little alteration in the local or general condition. Vomiting continued, the vomit matter being bile-stained. The pain was dull and aching, its acuteness probably lessened by the opiate. The following morning there was considerable tympanitis, rigidity and tenderness, most marked in the epigastric region, and general jaundice supervened. Vomiting had somewhat lessened. The pain was still dull and boring in character. While attempting to get out of bed about 11 a. m. she suddenly became semi-conscious and died in a very short time.

Autopsy.—The autopsy, performed three and one-half hours after death, revealed the following condition:

The body was that of an adult female, white, apparent age 55, weight 145 pounds, height 5 feet 5 inches. The body was well-developed, well-nourished and rather fleshy. There was considerable general jaundice. There was postmortem rigidity in the neck, hands and feet. Postmortem lividity was slight posteriorly. The abdomen was prominent, tense and tympanitic. Liver dullness was indefinite.

On opening the abdominal cavity, the omentum and the intestines protruded. The intestines were considerably distended with gas. The omentum and peritoneum were of a pink, light-red color, and a thin, dark-red, odorless fluid ran out of the incision. About 350 c.c. was diffused through the general peritoneal cavity. The appendix was 6 cm. long and lay to the inner side of the cecum, curled behind the lower end of the ileum, and was apparently normal. The pyloric half of the stomach, the duodenum and the transverse colon were pushed forward by a dark-red, rather soft mass, lying posterior to them, and apparently involving the whole of the pancreas. Scattered throughout the omentum, the mesentery and the walls of the stomach and intestines were numerous small, white nodules, varying in size from a pin head to a split pea, rather soft, white on section, and most abundant in the neighborhood of the pancreas. All the structures in the immediate surroundings of the pancreas were intensely swollen and edematous and infiltrated with a fluid similar to that lying free in the peritoneal cavity. The infiltration and edema extended into the retroperitoneal tissues, surrounding both kidneys, and down into the postcecal tissue on the right side, giving the whole a boggy, sodden appearance and a dark-red color. The mass involving the pancreas consisted of coagulated blood diffused through the whole of the pancreas, except a very small portion of the head and tail. The source of the bleeding could not be found. The mucous membrane of the stomach and intestines were pale in color, swollen and edematous.

The liver was of a pale, yellowish-red color, softened. The lobules were indistinct. The gall bladder contained about 20 c.c. of dark, reddish-brown bile and a moderate number of small, brown-colored calculi. The bile ducts were patent and opened by a separate orifice from that of the pancreas into the duodenum.

The spleen was slightly softened, and the splenic artery and vein were filled with coagulated blood.

The kidneys contained several small cysts and were markedly congested. The bladder contained a few centimeters of slightly albuminous urine, but no sugar.

Apart from the abdominal conditions, there was some fatty infiltration of the heart, marked atheromatous degeneration of the large arteries, with some calcareous deposit, bilateral chronic pleuritic adhesions, cicatricial contraction of the lower lobe of the right lung, excess of cerebrospinal fluid, considerable subarachnoidal exudate and marked atheroma of the arteries at the base of the brain.

* Read before the Marion County Medical Society, Indianapolis.

REMARKS.

Incomplete as the clinical report is, it yet indicates some of the most prominent symptoms that should lead one to suspect an acute involvement of the pancreas. The onset of this condition is usually sudden, but may be preceded by epigastric uneasiness for a day or two. It occurs more frequently in adult males, and particularly in fleshy people. It usually begins with abdominal pain, which is intense, more or less diffuse and persistent, with paroxysmal exacerbations. It is increased by movement, and is associated with well-marked tenderness above the umbilicus, distention of the superior abdominal region and by vomiting. Nausea and vomiting are early symptoms and increase in severity. No relief follows the act of vomiting. The vomited matter consists of food and mucus, later of bile and blood in various stages of degeneration.

A condition of collapse soon follows. The abdomen usually becomes distended and tender. The bowels, as a rule, are constipated, rarely there is diarrhea. Slight jaundice is usually present and increases the longer the patient lives. The mass may be palpable but usually the distention and tenderness are so great as to render palpation very difficult, if not impossible except under anesthesia. Severe attacks are usually fatal in 24 hours. When less acute, a gangrenous condition is often produced and proves fatal in from two to five days from absorption of the toxic material. When the condition is still less acute it may lead to abscess formation, or become subacute, or chronic; and in mild forms it may lead to resolution and recovery.

The hemorrhage may precede or take place during the inflammatory process. If it precedes the inflammation, the bleeding is usually within and without the glandular substance, and usually runs an extremely acute course. If it occurs during the inflammatory process, the bleeding is less profuse and runs a less acute course.

The diagnosis is difficult, as there are several conditions with a similar group of symptoms. The principal ones are: 1, Acute ptomain poisoning; 2, perforation of a gastric or duodenal ulcer; 3, gangrenous appendicitis; 4, phlegmonous cholecystitis; 5, acute intestinal obstruction.

Judging from the important part taken in the digestive process by the pancreatic secretion that is discharged into the duodenum, and in the process of metabolism by the internal secretion that is given off by the pancreas to the blood or lymph stream or both, one would expect that the clinical manifestations of a diseased condition would be so characteristic that a diagnosis would be comparatively easy, but there are several reasons why this is not the case:

1. The pancreas is rarely involved in a pathologic process without other organs being affected, particularly the biliary ducts, the stomach, and the duodenum.
2. Every function performed by the pancreas can be performed to some extent by some other organ in the body except the glycogenic function.
3. The greater portion of the gland may be destroyed and yet the remaining portion apparently may be able to carry on the normal function of the entire gland.

While these conditions may give rise to very conflicting and perplexing combinations of symptoms, yet there are some pronounced features manifested which should lead one to suspect a diseased condition of that special organ. Fitz has laid down a rule that when a previously healthy person or sufferer from indigestion is suddenly seized with violent pains in the epigastrium, followed by vomiting and collapse, and within twenty-four hours by a circumscribed epigastric swelling, tympanitis, and resistance, with slight rise of temperature, one should suspect acute pancreatitis.

In a lecture delivered before the Royal College of Surgeons of England, Mr. P. J. Cammidge[1] stated that there were present in the urine certain products which were almost if not quite pathognomonic of acute pancreatitis. His method of examination to prove their presence is as follows: To 10 c.c. of filtered urine is added 1 c.c. of strong hydrochloric acid, boiled gently for 10 minutes on a sandbath. A mixture of 5 c.c. of filtered urine and 5 c.c. of distilled water is then added and the whole cooled in running water. The excess of acid is then neutralized by slowly adding 4 grams of lead carbonate. The whole is again filtered, the flask rinsed with 5 c.c. of distilled water. To this are now added 2 grams of sodium acetate and 0.75 gram of phenylhydrazin hydrochlorate and boiled for three to four minutes on the sandbath. It is then poured into a test tube and allowed to cool undisturbed, when a flocculent precipitate forms consisting of rosettes of golden-yellow crystals. The presence of sugar of albumin must be previously gotten rid of, as these substances interfere with the process and the results. As somewhat similar results are obtained in patients suffering from certain diseases in which active tissue changes are going on, a differentiating test must be applied, which consists in taking 20 c.c. of filtered urine and adding 10 c.c. of saturated aqueous solution of mercuric chlorid, filtering. To 10 c.c. of the filtrate add 1 c.c. of strong hydrochloric acid and boil as in the former process. It is then diluted with 5 c.c. of the former filtrate, and 10 c.c. of distilled water, cooled and treated as in the former instance.

The practical results of these examinations of the urine by these two methods Cammidge summarized as follows: If no crystals are obtained by either method the pancreas is not at fault, and the explanation of the symptoms must be sought for elsewhere. If crystals are obtained by the first method and not by the second, active inflammation of the pancreas is present and surgical interference is generally indicated. In acute inflammation of the pancreas the crystals are fine and dissolve in a 33 per cent. solution of sulphuric acid in about thirty seconds. In chronic inflammation the crystals are coarser and dissolve in one to two minutes. If crystals are obtained by both methods there may exist: 1, Malignant disease of the pancreas; 2, chronic disease of the pancreas; 3, non-pancreatic diseases.

In malignant disease the crystals are very coarse, and require from three to five minutes to dissolve, and operation is contraindicated. In chronic inflammation the crystals are smaller and dissolve in from one to two minutes. In non-pancreatic disease the crystals dissolve in one minute. Thus it seems that the size of the crystals and their solubility are directly dependent on the acuteness of the inflammatory process.

As regards the treatment, the pathologic condition indicates that practically only one line of treatment can be beneficial, and that is evacuation of the septic material, arrest of the hemorrhage, and free drainage by surgical methods. Even though the mortality following operation in the acute stage is very high, 36 out of 59 operative cases proving fatal, yet when one considers the fact that the disease almost invariably ends fatally when not treated surgically, an operation is strongly indicated.

POISONING DUE TO THE PAPAW (*ASIMINA TRILOBA*).

M. A. BARBER.
Associate Professor of Bacteriology and Pathology, University of Kansas.
LAWRENCE, KAN.

Some seven or eight years ago, in late summer, I found in this vicinity several fruits of the common papaw which had fallen to the ground and ripened prematurely. The fruit was ripe enough to be palatable, and I ate a small portion, perhaps equivalent to one fruit. About six hours later I experienced an urticaria, beginning with itching and burning in the hair at the back of the head and soon extending over a considerable part of the body. Accompanying symptoms were nausea, throbbing at the head and disturbance of the bowels. The urticaria would at times diminish suddenly; then the nausea would increase, to be relieved a few moments later with the reappearance of the "hives." The symptoms lasted several hours, but they had almost wholly disappeared by the next morning and the skin had resumed its normal condition. A friend ate some of the fruit at the same time that I did, but suffered no ill effects whatever.

I had never before experienced similar symptoms, and I suspected the papaw; but I was not sure of the cause until, a season or two later, I had an opportunity of repeating the experiment. This came when, visiting the same grove at about the same time of the year as on the former occasion, I found similar fruits and ate a small quantity to test the effect. The same train of symptoms followed after about the same interval of time, though this time the illness was considerably more severe, and I experienced a decided faintness along with the symptoms of the previous case.

In the autumn of 1904 I undertook some more systematic experiments on the nature of this poisoning. It seemed to me worth while to investigate the matter for the sake of any information I might be able to obtain on the general question of poisoning resulting from individual susceptibility to the action of certain fruits, especially since I had a subject so conveniently at hand. I desired particularly to find out if repeated poisoning confers any immunity on the susceptible person, and to ascertain if any particular condition of the fruit is necessary in order to cause the illness. I have eaten ripe papaws since childhood, but had never before experienced poisoning from them or from any other fruit. I was also interested in the papaw itself; for, while not altogether a popular fruit, it is much eaten in many parts of the Mississippi Valley, where it is abundant, and some attempts are being made to cultivate it and obtain improved varieties of the species.

The following is a brief summary of my experiments:

October 1. Ate small portions of several fruits. Eleven hours later I experienced urticaria and some of the other symptoms noted above, but the illness was very mild.

October 7. Ate 24 grams of fruit brought to me from a locality at some distance from the source of the fruits used in the other experiments. The fruit was probably picked up from the ground, because it was slightly blackened on one side. After about ten hours I experienced urticaria with slight nausea, but the symptoms were comparatively insignificant.

October 10. Ate 21 grams of the same fruit, which had been kept in a refrigerator since October 8, and had ripened somewhat in the interval. No effect.

October 15 to October 18. Ate a whole fruit ripe from the tree and a whole fruit ripe from the ground. Also ate a whole fruit not fully ripened at the time of collection, but allowed to ripen three days after gathering, and ate 21 grams of a fruit taken green from the tree.

In none of these four experiments was there any effect. All of these experiments were made with fruit apparently in a normal condition, and differing only in the degree and manner of ripening.

On account of all these failures I began to suspect that I might have acquired some degree of immunity to this fruit, but the next experiment disproved this theory.

October 19. Ate 23 grams of a fruit which had fallen prematurely from the tree. The quantity eaten was equivalent to about one-third of a fruit of average size. It had been kept four days at room temperature and had ripened somewhat at the center, but the outer part was still hard. Its taste was bitter.

The effects began to be noticed three and one-half hours later. An urticaria began on the crown of the head, then appeared on the body where suspender or garter pressed the skin. Then it spread over the whole body, the face, hands and feet being the latest to be covered. Nausea with vomiting, faintness, chill and disturbance of the bowels followed, the symptoms being decidedly more severe than in any previous case. The following day little remained of the illness, except that the face and hands were slightly swollen, the throat a trifle sore and the skin ready to break out into a mild urticaria on irritation.

This experiment, the most decisive of all, indicated that the four previous poisonings, two of them within twenty days, had not conferred any great degree of immunity; and, further, that an abnormal condition of the fruit seems, in my case, at least, to be necessary in order that poisoning may take place.

During the autumn of 1905 I resumed the experiments, trying smaller doses of fruit similar to the one which had caused the poisoning of the previous year.

September 11, I ate 3 grams of such fruit, and September 12, 10 grams of the same specimen kept on ice over night. October 10, I tried 25 grams of a fruit taken from the tree soft but not fully ripe.

In none of these experiments was there any effect. It would seem that the dosage was too small, or more probably, the fruit not in the condition in which it is poisonous for me.

During the past year or so I have made many inquiries of physicians and others in regard to poisoning from this fruit, and I have learned of fifteen or twenty cases attributed to this cause. Dr. Cleveland of Burlington, Kan., a locality where the papaw is abundant, told me of two cases, in one of which he found the patient unconscious. On recovery to consciousness the patient exhibited urticaria. Dr. Manson of the same locality reports several cases of poisoning due sometimes to eating the fruit and sometimes to the mere contact of the surface of the fruit to the skin. Dr. J. E. Buckman of Modesto, Ill., wrote me of three cases which he attributes to the eating of papaws. In all three cases the patients reported that the fruit they had eaten was so ripe that the surfaces had begun to turn black. One case was characterized by fever, a burning sensation in the stomach and throat, with an eruption on the membrane of the throat. There was an eruption externally also, especially on the face where pustules formed which were large and slow to heal. The other two cases exhibited similar characteristics, except that there was no internal symptoms. Both patients stated that they had been poisoned before by papaws.

Professor Havenhill of the department of pharmacy in the University of Kansas has reported a case to me in which an urticaria appears several days after eating the fruit whenever the skin is irritated. Mr. Benjamin Buckman, a horticulturist of Farmingdale, Ill, reports to me that poisoning from papaws occurs in his family and that one member is affected by merely being in a room with the fruit without any contact with it. I am told that there are persons who can eat the fruit with impunity if care is taken to avoid touching the face with the exterior of the fruit, and it is believed by some that persons who are susceptible to ivy poisoning are more likely to be sensitive to the papaw. In my own experiments I have several times rubbed the skin with the surfaces of fruit, but never noticed any effect. I am not in the least subject to ivy poison.

Horticulturists report two varieties of papaw, in one of which the mature fruit has white flesh, in the other yellow; and one person told me that there is a notion current that white-fleshed variety is poisonous to susceptible persons, while the yellow-fleshed one is harmless. I have been unable to get any confirmation of this view. In only a few cases could I get exact data regarding the condition of the fruit eaten, but it is presumed that the fruit was in most cases ripe, since the unripe fruit is hardly palatable.

Many persons whom I have interviewed on this subject had lived where papaws are abundant, and had been accustomed to eating them, but had never heard of poisoning of any kind resulting from their use, and the majority of physicians of whom I inquired have never had a case of this kind. So it may be presumed that severe poisoning is comparatively rare, and that the milder poisoning may often be attributed to some other plant.

Summarizing the results of my observations and experiments, it may be stated that poisoning due to the papaw exists, but a special predisposition on the part of the person is necessary. The surfaces of the fruit may act as an external poison as well as the pulp an internal, though persons susceptible to the one form of poisoning are not necessarily susceptible to the other. The condition of the fruit is, with some persons at least, of importance; and there is evidence that normally ripened fruits are less likely to be harmful. The symptoms of internal poisoning resemble those of poisoning due to oysters or strawberries in susceptible persons, and in my case there was some relation between the strength of the dose and the promptness with which the symptoms appeared. There could hardly be any question of ptomain poisoning, since the fruits which were poisonous to me, at least, were rather under than over-ripe; and in one experiment a fruit which had caused illness became harmless in nearly the same dose after ripening somewhat. The external poisoning varies from a mild urticaria to a condition resembling severe ivy poisoning. There is no evidence of immunity resulting from previous attacks.

Resection of Thirteen Feet of Intestine.—The *Semaine Médicale* states that Pauchet of Amiens recently resected a part of the ileum, on account of irreducible hernia, in a man rather below the ordinary height. The resected portion measured exactly 4 meters, or more than 13 feet. The patient was affected with diarrhea when he was dismissed and resumed his usual diet, but it was controlled by a drier diet. Our exchange thinks that this is the most extensive resection of the kind on record.

New Instrument

AN INHALER FOR ETHERIZATION

BY THE OPEN DROP METHOD.

ROBERT H. FERGUSON, A.M., M.D.
BOSTON.

It is not the purpose of this article to discuss the merits or advantages of the different methods of producing anesthesia by the inhalation of the vapor of ether. Whatever advantages may be claimed for the semi-open method or for the closed method, a large number of surgeons and anesthetists prefer the open method, which, to be of advantage, must be conducted by dropping the ether for inhalation rather than by pouring it into the inhaler. The number of those who prefer this open drop method is increasing, and while inhalers for the other methods are in abundance and modifications of the old ones are constantly being made, little has been done in the development of an inhaler for the open drop method.

Dr. Laplace, of the Medico-Chirurgical Hospital in Philadelphia, devised an inhaler for this method and deserves credit for the ingenuity manifested in producing so excellent an apparatus, but, ordinarily, no special mechanism is employed. Many etherizers practice the method of laying over the face a certain number of layers of surgical gauze and dropping the ether on them. To prevent irritation of the skin it is necessary to anoint the patient's face with some unguent, which, as a rule, permeates the lower layers of the gauze and renders them more or less impervious to the ether vapor. Further, if gauze alone is used there is much waste of ether, for, although the actual quantity lost may not be great, the proportion renders anesthesia more tardy and difficult. To obviate these troubles some cover the gauze with a sheet of absorbent cotton, in which a hole is torn and through this hole the ether is dropped on the gauze, which is sometimes kept away from the face by placing it over an ordinary Esmarch's chloroform inhaler. By this method, also, much ether is wasted, as the cotton absorbs it by capillary attraction.

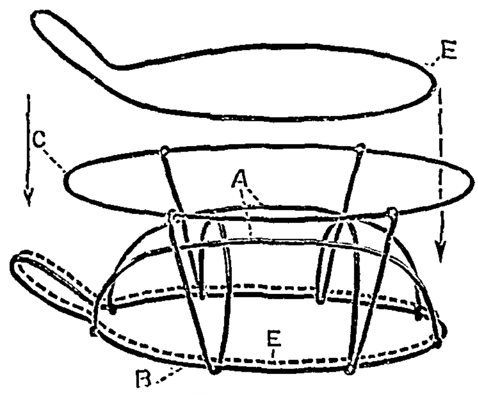

Figure 1

A description of the inhaler which I devised and which I have used for years with perfect satisfaction may be of general interest and is, therefore, here submitted.

This inhaler is intended to administer only air saturated with ether in only the quantity necessary to produce and maintain surgical anesthesia, although profound anesthesia may be maintained if desired. It consists of a metal wire frame (Fig. 1) over the convex portion of which (A) are stretched several thicknesses of surgical gauze (Fig. 2).

This gauze is held taut and in contact with the face wire (B) by means of a flexible wire (E). It will be seen that when thus arranged the apparatus embodies all the essentials of an Esmarch chloroform inhaler. It differs from the Esmarch, however, in that the face wire (B) should so come in contact with the face of the patient as to allow no admission of air between the inhaler and the face, a condition the reverse of what is necessary when chloroform is administered. The amount of gauze which should be employed depends on the size of the mesh of the gauze, for as much should be used as can be employed without in any way embarrassing the respiration of the patient. Ordinarily six to ten layers are sufficient. The wire frame with the gauze in place is then covered by a canton flannel bag (Fig. 3), so arranged that it fits snugly around the face wire (B) without impinging on the free space, and on top it draws up so as to leave an opening about an inch in diameter, through which the ether is to be dropped on to the gauze inside (Fig. 3, G).

When the apparatus is complete (Fig. 3) it is adapted for the administration of ether to a patient in the supine position. If it is necessary to have the patient in a lateral position, a cover may be used with an opening in the side instead of in the top.

When put together for use the apparatus consists of two chambers (K and M, Fig. 4), and when the ether is dropped through the opening (G) in the cover (F) it falls on the layer of surgical gauze (D), supported by the convex wire frame (A), and evaporates, thereby saturating the air in chamber K This air saturated with ether vapor is of higher specific gravity than pure air and falls through the gauze into chamber M, which is supported below by the face wire (B), so bent as to fit the patient's face and thereby to prevent the admission of air from below. Hence the patient inhales only the etherized air in chamber M.

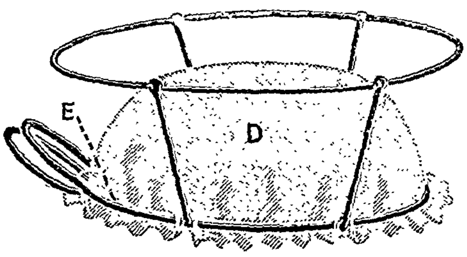

Figure 2.

When in use the wire frame first should be fitted accurately to the face of the patient by bending slightly the flexible face wire, and after the instrument is put together, as described above, it should be laid gently on the patient's face, who should be allowed to breathe through it and thus know that his respiration is not impeded. Tell him that the odor of ether may not be very agreeable, but if he breathes deeply he will not mind it. This will inspire confidence when he first smells the ether. Then, while deep respiration is in progress, allow a drop of ether to fall through the opening on to the gauze and follow this in a few seconds by another drop, and so on. Soon the respiratory passages become tolerant of the ether vapor, and the patient passes quietly into the first stage of anesthesia. The ether now may be dropped more frequently and surgical anesthesia will be induced, generally without any manifestation of a secondary stage, unless, possibly, a fixation of the chest for a few seconds, during which the ether should be continued and pushed by dropping it more frequently.

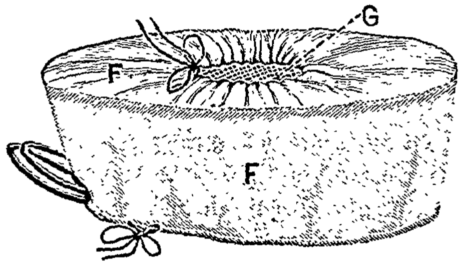

Figure 3.

A profound anesthesia may be maintained by continually dropping the ether on the gauze, but, by carefully watching the condition of the patient during the operation, an anesthesia just sufficient to keep the patient relaxed may be maintained. On removal of the inhaler a speedy recovery, usually free from nausea or vomiting, takes place.

By means of this inhaler surgical anesthesia may be produced in from two to five minutes with from four to six drams of ether, and for hysterectomy, lasting one hour and three-quarters, anesthesia has been kept up for one hour and forty minutes by using only three and one-half ounces of Squibb's ether for the total operation, and this is an average result. With alcoholic patients the inhaler works well. It is rare that anesthesia in such cases is not produced in from eight to ten minutes, although, of course, there are patients who do not respond easily to the administration of ether by this inhaler or by any other. The above figures are those of actual practice, when effort has been to see not how quickly but how well and comfortably to the patient the anesthesia could be induced.

At the end of each anesthesia the gauze should be thrown away, the cover put in the wash and the wire dipped in some non-corrosive antiseptic solution. For the next operation clean gauze and a fresh cover should be employed.

It has been claimed by some that bronchorrhea or bronchitis is often a necessary sequela of the open method of ether anesthesia. This is a mistake. Such difficulties are due to the erroneous use of the method. If the ether is too cold when introduced into the inhaler, or if it is poured into the instrument in such quantities as to reduce its own temperature by evaporation, some bronchial difficulty may be experienced, but if a few cans of ether are kept in the operating room so that when used the ether may be of the temperature of the room, or if the anesthetist warms the can thoroughly by immersing it in tepid water before opening it, and then drops (not pours) the ether into the inhaler, no difficulty will be experienced except in cases of idiosyncrasy in which the mucous membrane is very susceptible to the slightly irritant properties of ether.

Further, it should be remembered that bronchorrhea, bronchitis and the so-called ether pneumonia are due more to the chilling of the patient's body than to the inhalation of the ether. This may take place either during the operation from necessary or unnecessary exposure, or after the operation because the bed in which the patient is placed has not been sufficiently warmed, or from a draft in the recovery room or ward. Since rubber hot water beds for the operating table have been provided, as also proper care for the warmth of the patient after the operation, post-anesthetic bronchial and lung troubles have been greatly reduced in number. It is hardly necessary to add that only ether of a very low specific gravity and a high degree of purity should be used.

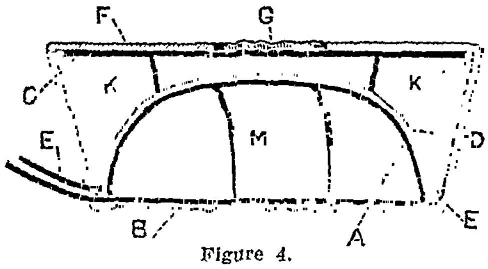

Figure 4.

This inhaler can also be used as an Esmarch chloroform inhaler for the administration of chloroform, as well as for ethyl bromid, but not for ethyl chlorid. The apparatus is simple, small, compact, cleanly and cheap.

Clinical Report

A CASE OF AINHUM.

Q. CINCINNATUS SMITH, M.D.
SAN DIEGO, CAL.

The following case came under my notice several years ago: The patient was a negress between 35 and 40 years of age, the daughter of a native African father, who was captured in Africa, sold into slavery when a boy, lived a slave in Tennessee, and died at the age of 115 years. The patient lost both small toes by ainhum and suffered great pain during their spontaneous amputation, which required several months to complete. During this time her general health was not seriously disturbed. This patient was the property of my father, the late Moab Stephen Smith, and lived to be about 90 years of age. I send this for record in the list of ainhum cases.

SATURDAY, DECEMBER 30, 1905.

THE INDEX.

It may be considered unusual for a journal to refer editorially to its index, because an index is an ordinary affair and is supposed to accompany the last number of the volume of all periodicals. But for several years we have been issuing with each volume an index to current literature, aside from the ordinary index, and as many of our readers, even those who have been reading The Journal for years, do not know what we are doing in this regard, we make it a point to call attention to it in this manner. The index that accompanies this number is something more than an index to the matter that has appeared in The Journal—it is a guide to the current medical literature for the six months covered.

Included in the pages from 2039 to 2058 is the ordinary index, but commencing on page 2059 is the Index to the Current Medical Literature, and it is to this that we want to call particular attention. In this will be found the titles of the original articles that have appeared in practically all of the important journals of this and foreign countries. On page 2085 commences the authors' index. While the Current Medical Literature is not as complete as, nor is it expected to take the place of, the *Index Medicus,* it will be found more practical for those who wish to look up the important articles that have appeared on any subject, and who do not want every case report, etc., that has been published.

We reprint this index, and with it the titles of the articles that are indexed. In this form it is much more convenient for reference than if the bound volume of The Journal has to be referred to. This reprint we supply at fifty cents a copy or seventy-five cents a year.

We respectfully ask those of our readers who are in the habit of looking up literature, and who have not used this index, to test its value, and to make any suggestions that may occur to them. We ask for criticisms so that we may make this index still more satisfactory and more practical.

SOME INTERESTING RESULTS OF TUMOR TRANSPLANTATION.

Within a very short time we have witnessed the method of research in the problems of malignant growth, which was limited almost entirely to histologic and statistical studies, changed to an experimental method that is fairly comparable with those of bacteriology. The discovery that many spontaneous tumors in the lower animals are capable of successful transplantation from one animal to another of the same species has made it possible to follow out careful cultural methods, in which the chief difficulty is the limited variety of culture media on which the tumors can be made to grow, namely, the bodies of animals of the same species as the host of the original tumor.

The first important experiments of this sort were those of Hanau, later followed by Leo Loeb and M. Herzog in this country, and by Jensen, Borrel and Michaelis abroad. In Ehrlich's laboratory in Frankfort, besides the well-known work on the problems of immunity there is a "carcinoma department," in which large series of transplantations of this kind have been undertaken. Some time ago[1] we described a number of experiments on transplantation of tumors in dogs made in this laboratory. Experiments on the much more easily transplanted tumors of domesticated mice, which occur spontaneously and in epidemics in laboratory animals, have also been conducted on a large scale, tables of the results having been exhibited at St. Louis. These tumors always arise primarily in the mammary glands of female mice, and the epidemics seem to be brought about by inoculation by the suckling young, which nurse one another's mothers most promiscuously. Of seventy-one such tumors ten were successfully transplanted, and at the time of the last report[2] had been carried as far as to the sixtieth generation. Among numerous observations one of the most significant is that while only the mammary glands of adult females are affected by the primary tumor, the transplantations are unaffected by the age or sex of the inoculated animal, indicating that the conditions necessary for the natural origination of a malignant tumor are very different from those under which the existing malignant cells can take root and grow.

We are particularly interested in this series of experiments in connection with our comments recently[1] on the subject of the occurrence of multiple primary malignant tumors of different natures in the same individual. We there pointed out that each variety of malignant tumors seems to be of quite specific nature and origin. In these mouse experiments of Ehrlich and Apolant, however, a remarkable result was obtained, not apparently in accord with this rule. A carcinoma had been transplanted from one mouse to another, preserving its original characteristics, until suddenly in the tenth generation it was observed that part of the growth was sarcomatous. The sarcomatous elements increased and the carcinomatous decreased with each generation until the fourteenth, when no more carcinoma was left, and for twenty-six more generations inoculations produced only purely sarcomatous tissue. This is certainly a most unique observation, and the proper interpretation of its meaning is of great importance. There is nothing to suggest that the carcinoma cells had undergone a metaplasia into

---

1. The Journal, Dec. 17, 1904, p. 1872.
2. Berl. klin. Wochft., 1905, vol. xlii, p. 872. Brief abstract in The Journal, xlv p. 880.

mesoblastic tissue. Perhaps as promising a suggestion as any yet made is that the result of transplanting from one animal to another for many generations a strain of connective tissue (namely, the stroma of the primary tumor, which always seems to live and grow in each implanted piece), has resulted in its acquiring a greatly increased power of growth in foreign organisms, until at last the energy of growth has been so exalted that it passes the normal bounds and becomes truly malignant.

This is analogous to the increase of virulence that results from passing bacteria from one host to another, and opens a new field of experiment.

It must be also considered, however, that these mouse tumors, which are now being used so much in the study of cancer problems, present several differences from typical carcinomas, even though histologically they are practically identical. One difference is their frequent epidemic occurrence among caged mice. Another is the frequence with which they spontaneously cease growing and undergo natural cure, which has made possible the experiments on the development of immune serum in mice with such healing tumors that are being carried on in Gaylord's laboratory in Buffalo. There can be no question about the histologic nature of the elements of the mixed tumors in Ehrlich's mice, a number of the leading pathologists in Germany having agreed with the diagnosis of sarcomatous and carcinomatous growth.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN THE UNITED STATES AND IN ENGLAND.

There can be no doubt but that in many respects the physical and economical conditions of the poor in England in general and in London in particular are giving rise to widespread feelings of misgiving among the more intelligent of the community at large. The number of unemployed, many of whom would not work if they had the opportunity, is appalling. Another feature of sinister import in the large manufacturing towns of England is the increasing physical, and it may be said also, mental degeneration of their workers. The fact is recognized at its full significance that this evil must be attacked at its root and that in any attempts to improve the race attention must be paid to the health of the young. The English Local Government Board has already initiated a revolution in poor-law procedure by an order last April for the feeding of hungry school children, and now the Board of Education department committee has followed suit with a report on the same subject and on the question of the medical inspection of children attending public elementary schools. This committee has issued recently a report dealing more or less exhaustively with these two subjects. The results of medical inspection, the committee says, "leave something to be desired and there is much opening for improvement." It is shown, however, so far as results of medical inspection are recorded, that diphtheria is now under such complete control in several areas that an outbreak can be stopped in a few days. Much also has been effected in the direction of securing greater cleanliness and freedom from vermin, and the inroads of ringworm have been appreciably checked. The condition of the children's eyesight has received close attention; defects have been discovered and spectacles have been provided. Steps have also been taken toward dealing with the difficult question of defective hearing.

In the section of the report referring to the feeding of children attending public elementary schools a series of recommendations for better organization has been made by the committee. One recommendation is to the effect that parents should be told clearly that they are in receipt of charitable relief when such is the case, and that greater effort might be made to obtain payment from parents for the whole or part cost of meals supplied to their children. The suggestion is further made that the children of families in temporary distress should be made the first care of any feeding agency.

Drunkenness in the parents is commented on as introducing a serious difficulty into any system of feeding the children. It is stated that when help is refused the children continue to starve, but that when assistance is given it only means more money for the parents to expend on drink.

Several of the large cities of this country preceded England in the medical inspection of school children. and with us the innovation has been attended with the most satisfactory results. With regard to the feeding of indigent school children, such a procedure is entirely opposed to the American spirit of independence. The only places in which its introduction is likely to take place is in those cities in which there is a large alien population. In European countries overcrowding is the rule, and in many cities in Great Britain, especially in England, improvidence and drunkenness have undoubtedly tended to aggravate matters. The concentration of the population in the large cities is a phase of the overcrowding question which is manifested almost to as great an extent in America as in Europe, and the evils connected therewith must be dealt with. On account of the size and resources of the United States the situation has not reached the acute stage, but, at the same time, signs are not lacking that the time is not far distant when the problem of how to deal with the surplus poor, ill-fed and degenerate population of the cities of this country will engross the attention of sanitarians and sociologists.

THE CHAMBER OF HORRORS.

After all the revelations concerning the venality of the trade in patent medicines it was not to be expected that anything worse could be said. It now seems that the first dissections were only preliminary. In the *Ladies' Home Journal,* January, 1906, are two articles on the subject by Mr. Mark Sullivan that are well calculated to make any decent man or woman shudder and in amazement to ask if human beings in this age are capable of such abject depravity. After this exposure men in the patent medicine trade should hardly expect to associate with any but the criminal classes. We learn that poor suffering deluded women are cajoled into writing their troubles—their most confidential secrets, their sexual relations, their defects in development of bust, and the rest—to the "doctor" of the company under the solemn promise of absolute secrecy. It is then set forth that these letters are first sorted by male clerks and answered by various "stock letters," after which the "richest" ones for young men and young women to read are passed around, even taken home by clerks and handed around among the neighbors. Finally, after salacity is satisfied and the poor victims cease to buy any more of their medicines the officers of the company gather up the letters and sell them to letter brokers and to other patent medicine concerns for a half cent each. Is not this "the limit?" Shall the postal service be used in this immoral traffic? Will the enlightened newspapers still continue to play their indispensable part in this worse than swindle? The horrors of the slave trade were no worse. The additional facts adduced regarding testimonials for patent medicines are less shocking, but no less interesting. We are informed that "testimonial brokers," through newspaper correspondents chiefly, offer for sale for any nostrum the testimonial of a United States Senator for $75 and of a Congressman for $40. Our representatives seem pretty cheap, but Mr. Sullivan's story shows how the price has been brought so low. The sales are often made in $5,000 lots, so that the trade is wholesale and affords the broker a considerable margin. In the last twelve months of exposure of corruption in American politics and business there has been nothing to approach the villainy of the "patent medicine" business.

CONVICTS AND HYGIENE.

From state after state there come complaints of the insanitary conditions of penitentiaries. Great efforts have been made to rectify these ill conditions, but governments proverbially move slowly. In the meantime, those who are segregated from society in order to limit their anti-social proclivities are in reality frequently condemned to death by tuberculosis. Some prisons are reported to be veritable hot-beds of this disease. The expense of meeting this state of affairs appears almost insurmountable when viewed in the light of the usual public inertia in regard to reforms. Meanwhile an increasing number of keen students of these problems turn to a proposal that seems revolutionary and that presents some practical difficulties of execution, but which nevertheless appeals strongly to the humane instincts and the scientific knowledge of physicians. This proposition is that "imprisonment at hard labor" shall be corrected to "compulsory farm labor" and perhaps to roadmaking. Farm work is healthy. As compared with confinement in a dingy prison, the promise of a chance of reform of the criminal is multiplied many fold by the healthy occupation, while the community would thereby cease its efforts to breed and to spread the infection of tuberculosis. It appears certain that this departure in penology will soon be under discussion by state legislatures, and there can be no doubt that the voice of the medical profession will join in the appeal of humanity and hygiene.

HYGIENIC METHODS OF EATING.

Apparently more provision is made to prevent our domestic animals from eating too hastily than is provided in the case of human beings. The horse frequently suffers from his unbecoming and unnecessary haste in eating; confronted by a generous display of oats in the feed-box, he can not resist the inclination to bolt one mouthful so that he may take another, at the expense of his health. According to the *Scientific American,* a feed-box has been invented in which only a mouthful is in sight at the bottom, and the horse has to eat this before more feed enters the feed-box. The horse is thus compelled to eat his meal in a more wholesome manner. It would be a wise provision to have some such arrangement in connection with the "quick-lunch" counters of the cities for men who feel the necessity or the inclination to bolt their food. It is certainly wise to safeguard the health of horses, but why allow human beings to go their own sweet way in unhygienic habits? We shall look for an adaptation of the horse feed-box scheme, at least for the quick-lunch counter.

UREMIC DERMATITIS.

Chiari of Prague[1] recently reported an interesting case of chronic nephritis with stomatitis and pharyngitis, enteritis and dermatitis (*akne et impetigo cachectica*). From the results of his careful anatomic study, gross and microscopic, Chiari reaches the conclusions that the different inflammations mentioned were of the same etiology, namely, uremic, and caused by the toxic action of urinary poisons on the mucous membranes involved and on the skin. The degree of dermatitis was unusually severe in this case, which was one of granular atrophy of the kidney following chronic nephritis. Various authors have described cutaneous eruptions in connection with uremia, and the occurrence of enteritis in this condition is well known, but the correlation of these processes as essentially of the same toxic origin seems to be a new departure of interest to clinicians and pathologists. The question as to the exact chemical nature of the substance or substances causing the inflammatory changes naturally suggests itself at once, as well as the great difficulties that now appear to stand in the way of its solution.

PHYSICIANS AND TARIFF.

Physicians have no professional interest in the tariff, but when the subject of tariff revision comes up there are several schedules in regard to which medical men of right have definite convictions. The duties on scientific instruments and books stand first in importance. The following duties of the present tariff were listed recently in a newspaper and are worth attention: Boric acid, 122 per cent. In 1904 $30,000 worth was imported, paying $36,000 in duty. Tannic acid, 103 per cent.; spirits of nitrous ether, 250 per cent.; sulphuric ether, 236 per cent.; spectacles and eye glasses, higher grades, 50 to 70 per cent., and cheaper grades, 116 per cent. Physicians will not protest because firecrackers pay 126 per cent. duty, even though the imports in 1904 were $266,000 and the duty $334,000.

---

Medical News

CALIFORNIA.

Beriberi.—A young Japanese is lying ill at the County Hospital, Los Angeles, suffering from beriberi combined with typhoid fever.

Loses Suit.—Dr. Peter A. Kearney, San Francisco, who sued Mrs. Theresa Ball for $25,000 for medical services alleged to have been rendered to her and her children, lost his suit, the jury finding a unanimous verdict in favor of Mrs. Bell.

Communicable Diseases.—Six cases of smallpox have been found at San Lorenzo, and all infected houses have been quarantined.——It is reported that there is no sign of abatement of the epidemic of diphtheria which is prevailing at Sierra City.

Personal.—Dr. Edward Hanlon, Marysville, has gone to Europe.——Dr. Thomas W. Prose, Woodland, has been appointed superintendent of the Odd Fellows' Home, Thermalite. ——Dr. and Mrs. William E. Hopkins, San Francisco, have returned from Europe.

Banquets.—Dr. William J. Walsh, San Francisco, coroner-elect, was the guest of honor at a banquet December 2, given by his associates in the Emergency Hospital service.——A banquet was given December 5 at the Claremont County Club, Oakland, in celebration of the fortieth anniversary of the incumbency of Dr. Warring Wilkinson as superintendent of the California Institute for the Deaf, Dumb and Blind at Berkeley.

DISTRICT OF COLUMBIA.

Police Surgeon Injured.—Dr. C. C. Marbury, police surgeon, was seriously injured by being thrown from his automobile in a collision with an electric car.

To Repeal Anti-Canteen Law.—Representative Morrell of Pennsylvania has introduced a bill repealing the anti-canteen law. The bill is in keeping with the report of the Committee on National Legislation of the American Medical Association adopted at the St. Paul meeting in 1901.

Health of the District.—The report of the health officer for the week ended December 16 shows that the total number of deaths was 106, and that there were 140 births. At the close of the week the following cases of contagious diseases were under treatment: Diphtheria, 62; scarlet fever, 29; typhoid fever, 105, and smallpox, 6.

IDAHO.

Personal.—Dr. Robert L. Nourse and family, Hailey, left for New York, on their way to Europe, December 14.

Hospital Notes.—Josephine Sanatorium, Weiser, has been opened to the public by Dr. Joseph R. Numbers.——Wallace Hospital is now in charge of Drs. J. E. St. Jean, Burke, and C. R. Mowery, Wardner, who purchased the institution from Dr. Charles W. Craik.——Pocatello General Hospital has been incorporated by Drs. William F. Howard, Hubert A. Castle and others, with a capital stock of $25,000.

ILLINOIS.

Hospital Nearly Completed.—The Dr. John Warner Hospital, Clinton, is already enclosed and will, it is expected, be dedicated February 15 next.

Diphtheria.—During the past six weeks diphtheria has occurred in more or less epidemic form in about 125 cities and villages spread over 61 of the 102 counties of the state. As a rule, the disease has been mild in character.

Smallpox.—The State Board of Health reports smallpox in Greene, Macoupin, Knox, Jersey, Logan, McLean, Adams and Pike counties. The disease has spread from Jerseyville, Jersey County, into Macoupin and Greene counties, which are adjacent.

Personal.—Dr. Grant Irwin, Quincy, was fined $32.95 December 3 for hunting in Missouri without a license.——Dr. Thomas Croswell, Streator, was made an honorary member of the Northern Central Illinois Medical Association at its recent meeting in Streator.——Dr. John B. Meigs, Manito, who was recently injured by a broncho, is recovering.

Another Victory for the State Board of Health.—In the case of the People vs. Peter R. Langdon, Kankakee, noted two weeks ago, the Supreme Court has rendered a decision in favor of the State Board of Health. Suit was brought against Langdon for practicing medicine without a license. His defense was based on the wording of section 2 of the Medical Practice Act providing that "no person shall hereafter begin the practice of medicine," etc., and the contention that he had not "begun" practice after the passage of the act. In this he was sustained both by the Circuit Court of Kankakee County and the Appelate Court. Following its policy of pushing all cases involving the validity of any section of the law to courts of the last resort, the State Board of Health appealed to the Supreme Court. In the opinion of the Supreme Court, delivered by Chief Justice Cartwright, it is held that section 9 of the act is specific and unmistakable in providing that "Any person practicing medicine or surgery or treating human ailments in the state without a certificate issued by the board" shall forfeit and pay certain penalties. It is further provided that the act is penal in character and to be strictly construed, but not with such technicality as to defeat its purpose; and further, that a single section of the act should not be construed to annul the apparent true meaning and intent of the whole act. The judgment of the appellate and circuit courts is reversed and the case remanded to the Circuit Court with directions to overrule the demurrer.

Chicago.

The Health Department's Forecast.—Should present conditions continue until the end of the year, the forecast made in July by the department of health that 1905 would have the lowest death rate on record, will be fully verified. The death rate for 1904 was 13.62 per 1,000, and 1905 promises to go below 13.5 per 1,000.

Deaths of the Week.—During the week ended December 23, 496 deaths were reported, equivalent to an annual death rate of 12.99 per 1,000. There were 54 deaths less than in the corresponding week of 1904, and 7 more than in the previous week of 1905. Pneumonia caused 83 deaths; consumption, 63; nephritis, 45; heart diseases, 38; violence, including suicide, 33; nervous diseases, 22, and cancer, 20.

INDIANA.

Buys Hospital Site.—The governor has paid $36,975 for the site of the Southeastern Indiana Hospital for the Insane at Madison.

Hospital Dedicated.—The new City Hospital, Bloomington, has been completed at a cost of $10,000, and was dedicated November 30.

Personal.—Dr. James A. Mattison, National Military Home, returned December 20 after a four months' stay in Europe.—— Dr. John W. Ballard, Logansport, has been appointed physician of Cass County.——Dr. James K. Hawes, Clifford, has been appointed secretary of the Bartholomew County Board of Health.

November Deaths from Violence.—Of the 159 deaths from violence in November, 10 were homicides, 27 suicides, and the remainder accidental. Eight women committed suicide; 7 used poison and 1 burned herself to death with coal oil. Of male suicides 5 chose hanging, 6 shooting, 1 cutting throat and 7 poison. The railroads killed 37 persons and street cars and interurbans, 1 person. There were 5 deaths from accidental drowning, 36 from crushing injuries, 7 from gunshot wounds, 24 from burns and scalds, 5 from drowning, 1 from electricity, 2 from horses and vehicles, 7 from mining, and 2 from poison.

November Deaths.—The total number of deaths reported in the state was 2,687, 121 more than in the corresponding month of last year. Tuberculosis caused 344 deaths; typhoid fever, 101; diphtheria, 33; scarlet fever, 11; whooping cough, 10; pneumonia, 219; diarrheal diseases, 42; cerebrospinal meningitis, 32; influenza, 13; puerperal fever, 10; cancer, 120, and violence, 159. The death rate for the state was at the annual rate of 12.3 per 1,000. The death rate for cities was 15, and the death rate of the country was 10.8. Of the cities having over 10,000 population, Lafayette reports the highest death rate, 20.5, and Marion the lowest, 11.2. Indianapolis shows a death rate of 16.1 and Evansville, 15.2 per 1,000.

MARYLAND.

Smallpox.—Four cases of smallpox have developed among the colored workmen in a brickyard at Dundalk, a river suburb of Baltimore.

Miltenberger's Estate.—The late Dr. George W. Miltenberger left his entire estate to his nephews and nieces, being a widower and having no children. His personalty amounted to $175,000.

Report of School for Feeble-Minded.—The ninth biennial report of the visitors of the Maryland Asylum and Training School for Feeble-minded, Owings Mills, has been completed. It has been found necessary to ask the Board of State Aid and Charities for an additional appropriation of $140,000,

$75,000 of which is required for additional buildings. There are 102 male and 98 female inmates, representing 21 counties, an increase of about 37 per cent. The majority of the inmates are between 11 and 16 years of age.

Withhold Aid from Private Institutions.—The Board of State Aid and Charities refuses to make appropriations for medical colleges, claiming that these institutions are essentially business enterprises in which the profits are divided among the owners. Two years ago the board left these institutions out of its list of recommendations, but they took the matter into their own hands and went direct to the legislature and got their appropriations, and it is understood they will endeavor to do the same thing this year. The hospitals and charitable institutions are all provided for, and the Johns Hopkins University will receive the same amount recommended two years ago.

Baltimore.

Jury Warns Against a Dangerous Nostrum.—The death of an infant from the use by its mother of a proprietary remedy known as "Kop's Baby's Friend" (concerning the composition of which, see The Journal, Nov. 25, 1905, page 1678), caused the jury of inquest to issue a warning to the public not to use that agent. The evidence before the jury showed that there was no way to account for the death unless the 10 drops of the medicine administered to it contained morphia sufficient to kill it. The state's attorney calls attention to the case in the newspapers and urges the need of a law prohibiting the sale of any patent or proprietary medicine containing any deadly drug unless it is labeled poison.

MASSACHUSETTS.

New Hospital.—The Bishop Stang estate, Fall River, has been purchased by Dr. Philemon E. Truesdale, and the building has been equipped as a private hospital with accommodation for 12 patients.

Bequests.—*Mrs. Helen G. Coburn leaves, among many other* large bequests, $50,000 to the Children's Hospital, Boston; $75,000 to the Massachusetts General Hospital, $25,000 to the Lawrence City Hospital, and $10,000 to the Instruction District Nursing Association.——By the will of John Bartlett of Cambridge the Woman's Aid Association of the Cambridge Hospital receives $5,000.——The Free Hospital for Women, Boston, will receive $1,000 by the will of Harriet M. Gilbert.

Deaths and Diseases.—There were reported to the Boston Board of Health for the 10 weeks ended December 2, 1,886 deaths, as compared with 1,962 during the same period last year. Of these 364 were under 1 year old, 514 under 5, and 417 over 60. There were 341 cases of diphtheria, with 16 deaths; 203 of scarlet fever, with 3 deaths; 256 of typhoid fever, with 34 deaths; 733 of measles, with 9 deaths; 423 of tuberculosis, with 220 deaths. Pneumonia caused 197 deaths; whooping cough, 5; heart disease, 209; bronchitis, 51, and marasmus, 67.

MICHIGAN.

Personal.—Dr. Johnston B. Kennedy has been appointed a member of the Detroit health board.——Dr. Thomas M. Koon, health officer of Grand Rapids, fell on the ice December 17 and injured his knee.

Historic Building Unsafe.—The regents of the State University, Ann Arbor, have decided to condemn the west end of the old medical building. No classes will be heard in its halls after the close of the first semester.

Accused Go Free.—In the second trial of George E. Bliss, Maple Rapids, for manslaughter through an alleged criminal operation, the jury disagreed and the case was dropped from the calendar.——J. F. Hare, Detroit, against whom the charge of attempted illegal operation was made by Elsie Priemel, was acquitted, the judge saying that he did not think any jury would believe the prosecuting witness.

Valedico.—With an editorial in the December *Bulletin*, bearing this title, Dr. Cressy L. Wilbur announces his retirement after 13 years of service as chief of the division of vital statistics of the State Board of Health. The editorial closes as follows:

> I have seen the mortality statistics develop from a weak, discredited system to a model service awarded the highest honors among the registration states.
>
> Michigan now stands on the threshold of a new period of achievement dependent on the enforcement of the new law for births.
>
> God speed the work! I have only thanks and best wishes for all the friends of the past years who as registrars, health officers, physicians, undertakers, officials of the Department and members of the Legislature have aided to make the service effective and a credit to the state, but must especially remember the faithful workers in the office force who have carried out the details of administration. Good bye!

November Mortality of Michigan.—The total number of deaths for November was 2,644, representing an annual death rate of 12.6 per 1,000. There were 445 deaths of infants under 1 year of age; 164 deaths of children aged 1 to 4 years, inclusive, and 791 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 189; typhoid fever, 93; diphtheria, 71; scarlet fever, 22; measles, 3; whooping cough, 11; pneumonia, 187; diarrheal diseases of infants, 74; influenza, 17; cancer, 143, and accidents and violence, 158. The deaths from pneumonia more than doubled in number, as compared with the preceding month, and influenza also increased, although the total number of deaths from this cause was only 17. A marked decrease was shown in diarrheal diseases. There was only one death from smallpox.

MISSOURI.

New Dispensary.—On December 14 the St. Louis Obstetric Dispensary was formally opened in its new quarters at 711 Carr Street. This institution was founded in October, 1904, under the auspices of the St. Louis University, and is at present maintained with funds provided by a ladies' auxiliary board.

Indecent Advertiser Fined.—As a result of the prosecution of the medical firms who insert indecent advertisements in the St. Louis press, which is contrary to a city ordinance, one of these practitioners has been fined $50 and costs in the City Court. This crusade was undertaken by the city attorney as a result of resolutions introduced and passed by the St. Louis Medical Society. The next order of business along this line wil be the prosecution of the newspapers who insert the advertisements, as they are equally guilty under the ordinances referred to. It is worthy of note in this connection to observe that not a line referring to the above conviction was seen in the daily press, although such a conviction should naturally be regarded as a news item by the papers. Is this another indication of the "criminal alliance between the newspapers and the outlaw practitioners"?

NEW YORK.

New York City.

Varioloid at Governor's Island.—Two military prisoners recently sent to Governor's Island for confinement in Castle William, developed varioloid and are quarantined in tents near the post hospital.

Hospital Fire.—Fire occurred in the boiler room of the Cumberland Street Hospital, Brooklyn, December 17. At the time there were about 200 patients in the hospital, but the firemen performed their duties so carefully that the patients were not alarmed. The damage was about $500.

Personal.—Dr. and Mrs. Valentine Mott returned on the *Koenig Albert*, from the Mediterranean, December 20.——Dr. William S. Bainbridge has recently been appointed consulting surgeon to St. Andrew's Convalescent Hospital.——Dr. Rudolph F. Herriman, Brooklyn, has been appointed consulting surgeon to Jamaica Hospital.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended December 16, 673 cases of measles, with 5 deaths; 409 cases of diphtheria, with 30 deaths; 406 cases of tuberculosis, with 144 deaths; 170 cases of scarlet fever, with 4 deaths; 117 cases of typhoid fever, with 17 deaths; 29 cases of cerebrospinal meningitis, with 17 deaths, and 196 cases of varicella, a total of 1,900 cases, with 217 deaths.

Hospital Bequests.—Isaac Guggenheim has announced to the board of directors of the Sydenham Hospital that he will give $250,000, provided the board raises a like amount, and stipulating that the money should go toward the erection of a new building. Mr. Guggenheim has just given the hospital $20,000 to be used in paying running expenses.——According to the will of Frederick Uhlmann, who died at the German Hospital on December 13, the Mount Sinai Hospital and the German Hospital will each receive $5,000.——In the new hospital shortly to be opened by the Sisters of St. Francis, which is located between One Hundred and Forty-second and One Hundred and Forty-third streets, there will be a ward of 50 beds equipped by Mrs. Clara Greenhut.

NORTH CAROLINA.

Personal.—Dr. Paul V. Anderson, Wilson, N. C., has recently been elected assistant physician of the State Hospital for the Insane, Morganton, vice Dr. Richard H. Speight, Jr., resigned.

New Hospital.—In addition to the three small hospitals of excellent grade and several sanatoria, another addition has recently been made to the medical institutions of Asheville in the Asheville Medical and Surgical Institute, in charge of Drs. Lewis B. McBrayer and Willard P. Whittington.

Many Convicted.—At the recent session of the Superior Court in Murphy, Cherokee County, N. C., more than 50 per cent. of the practicing physicians of the county were placed on trial for illegal practice of medicine. All were convicted and the judge sentenced each to a term on the county roads of an adjoining county some 90 miles away, but enjoined the clerk not to issue any capiases to enforce the road duty until complaint that attempts to continue the practice of medicine was made to him.

OHIO.

Marion County Society Meeting.—At the annual meeting of the Marion County Medical Society, held at Marion, December 5, the following officers were elected: Dr. Elmer O. Richardson, president; Dr. Filmore Young, vice-president; Dr. John W. Adair, secretary; Dr. J. M. Hoskins, treasurer; Dr. Dana O. Weeks, delegate to the state medical association; Dr. A. Melville Crane, alternate, and Drs. C. T. Wiant and Francis M. Baldwin, censors, all of Marion.

Shipping Liquors by Other Names Stopped.—The commissioner of internal revenue has decreed that shipping liquors by names other than those by which they are known to the trade is contrary to the internal revenue laws and must be stopped. It does not make any difference, he adds, that these names have been registered. Under the names of "cream of hops" and "hop tea," among a number of other names equally fanciful, many brands of malt liquors have been slipped into places regardless of local option laws. The commissioner also states that dealers must stop billing whisky as "witch hazel," "oil" and "tonic" when shipping to customers. Bills of lading must show just exactly what is contained in the package.

Privileged Communications.—The Supreme Court of the State of Ohio, in the recent case of the Metropolitan Life Insurance Company vs. Howe, has made the following ruling: "It is not competent to prove by a physician the communication made to him in that relation, but such physician may testify as to facts which are within his knowledge, independent of such communication. He may testify as to the condition and state of his patient as well as the treatment by him prescribed for his patient." In this connection it is reliably stated that the efforts of the counsel of Major Taggart in the recent Taggart divorce trial to obtain the hospital records of his wife's illness would have been successful had it not been that the law of the state explicitly says that such documents can not be conveyed from one county to another for purposes of evidence. Had the trial taken place in Hamilton instead of in Wayne, County, these hospital records must have been produced. Both of these institutions show that there must be something radically wrong with the heretofore highly cherished confidential relationship of physician and patient. It is expected that a bill will be introduced in the next legislature to relieve this condition.

PENNSYLVANIA.

Hospital Gift.—Mr. George F. Baer, president of the Reading Railroad Company, presented a check of $500 to the Reading Hospital as a Christmas gift.

Personal.—Dr. Isaiah F. Everhart, Scranton, has announced that he will present his natural history collection to the city of Scranton, and will erect a $50,000 building for its accommodation at Nayaug Park.

Vital Statistics Law.—All births and deaths on and after January 1 next must be registered within ten days of their occurrence, according to the new law regulating vital statistics, which will go into effect at that time. A failure to comply with this law entails a fine ranging from $5 to $50. The registration must be made at the bureau of health. The law requires that in the absence of the services of a physician and nurse, the father or mother or other person on the premises must report a birth. Births to the number of 28,832 were reported between Jan. 1 and Dec. 1, 1905. There were 32,137 births last year. The figures for 1904 were about 1,100 more than those reported in 1903. The reports of the health bureau show that January, July and August were the heaviest months for births in 1905, while March and September were the lightest.

Philadelphia.

Land for Hospital.—The estate of H. H. Houston has presented to the Chestnut Hill Hospital a plot of ground 20x225 feet.

Bequest.—By the will of Mary A. Cooper the Methodist Home for the Aged received $1,000, the Methodist Hospital $1,000 and the Methodist Orphanage $500.

Personal.—Dr. J. William White was the guest of the President in Washington, December 21.——The coroner has selected Drs. J. Albert Bolin and William S. Wadsworth as his physicians at a salary of $2,500 per annum.

Medical Men Entertained.—Dr. Alfred R. Allen gave a dinner to members of the medical faculty of the University of Pennsylvania at his residence, December 21. The guests included Drs. Alfred Stengel, Allen J. Smith, William G. Spiller, John Marshal, Richard C. Norris, J. P. Crozer Griffith and George C. Stout.

Appropriation for Blockley.—Since the exposure of the conditions at the Philadelphia Hospital by the director of public health and charities, Dr. William M. L. Coplin, the institution has been inspected by council's finance sub-committees on appropriations, which found the conditions of the hospital practically as reported in The Journal, December 16, and recognized the importance of immediate relief. They, therefore, will recommend to councils an appropriation of $100,000 for the immediate amelioration of the present conditions.

Health Report.—The total number of deaths for the week ended December 23 aggregated 524, as compared with 509 last week and 509 for the corresponding week of 1904. The principal causes of death were: Typhoid fever, 14; diphtheria, 15; tuberculosis, 55; cancer, 20; diabetes, 5; apoplexy, 20; heart disease, 49; acute pulmonary disease, 114; enteritis, 10; appendicitis, 6; Bright's disease, 46; suicide, 5; accidents, 19, and marasmus, 4. Of the deaths reported, 96 were due to pneumonia. There were 274 cases of contagious disease reported, with 29 deaths, as compared with 240 cases and 26 deaths reported in the previous week.

GENERAL.

Yellow Fever in Cuba.—Dr. Carlos Finlay, chief sanitary officer of Cuba, reports that the total number of yellow fever cases in Cuba since October 17 till December 14, is 57. Of these one developed in Matanzas City, another at Alacranes, and a third at Real Campina, Santa Clara province. All the patients apparently were infected in Havana. The largest number in treatment at any time, 22, December 6; December 14, only 16.

Inspection of Immigrants.—*Public Health Reports* states that on request of the Secretary of the Treasury the Department of State issued the following amended instructions by telegraph, December 5, to the consuls at Liverpool, Southampton, Hamburg, Bremen, Antwerp, Rotterdam, and Havre, and a circular of instruction was issued to the other consuls at seaports in continental Europe and in Great Britain:

> All immigrants from Russia must be detained five days at the port of embarkation for the United States under medical observation, and if during such detention any quarantinable disease appears or is suspected among them further detention and disinfection must be imposed, as provided by the Treasury regulations. If, however, the American consul or consular agent is satisfied that inspection of Russian immigrants and whatever disinfection of baggage that may be necessary has been accomplished at the Russian frontier, the time occupied in transit by said immigrants from the Russian frontier to the port of embarkation to the United States may be counted in the five days detention required by the United States regulations.

Medical Officer Honored.—A congressional medal of honor has been bestowed on Captain James Robb Church, assistant surgeon United States Army, now at Fort Robinson, Nebraska, who was one of the medical officers attached to Colonel Wood's regiment of rough riders in the fighting at Las Guasimas, June 24, 1898. The following letter from Assistant Secretary Oliver of the War Department makes this explanation of the award:

> On this occasion Captain Church, who was then serving as assistant surgeon, 1st United States Volunteer Cavalry, in addition to performing carefully the duties appertaining to that position, voluntarily and unaided carried several seriously wounded men from the firing line to a secure position in the rear, in each instance being subjected to a very heavy fire and exposure to danger.

Dr. Church was born in Washington, D. C., in 1866. He was graduated from Columbia Medical College in 1893. After receiving his degree in medicine he served as resident physician of the Emergency Hospital for several years. When the First United States Volunteer Cavalry—the rough riders—was organized, he was commissioned therein as assistant surgeon, with the rank of first liteutenant. During the greater part of the stay of the organization in Cuba, Dr. Church, by reason of the enforced absence of the senior medical officer, served as the regimental surgeon and was in charge of the hospital during the trying days after the fighting ceased and the dread Cuban fever was making its appearance.

Correspondence

The Burning of the Books.

Friar's Point, Miss., Dec. 23, 1905.

To the Editor: In The Journal, December 16, is an article by Dr. Bayard Holmes, in which the doctor takes the position (if I understand him) that *all* text-books of medicine should be burned after being in print ten years. He says: "If a man has done his work before he is 50 and ought then to step aside and give place to the young, the medical text-book has outlived its usefulness in one-tenth of that time." In the first place, I feel sure there are very many men in the medical profession, as well as in other walks in life, who can and do a great deal of good work after they are 50. Dr. Osler would hardly admit his work complete, and doubtless would enter a very vigorous protest to being "laid on the shelf." While I am as strong an advocate of progress as any man, and although I have reached the age when I should step aside, I try to keep up with the times and do not feel like stepping aside, as I am sure that there is much work for me to do yet. I have in my library works on practice extending from Dunglison, 1842, to Hare, 1905. I find it interesting and instructive to refer to these "antiquated" works occasionally and sometimes I refer to them to find "where we are at," as it is an indisputable fact that "the pendulum swings," hence authorities often find a reversal of opinion forced on them. I for one am not willing to admit that the experience and observations of those old "fathers in medicine" are absolutely worthless to us, for I find, by comparison, that in many instances authorities of the present era have not made any very perceptible progress over the theories as advanced several years ago. I feel sure that those old fellows stumbled on the truth occasionally (perhaps by accident), as can be proved by reference to some of those books and those of the present era. For instance, 50 years ago "blood letting" was routine practice, 25 years ago it was obsolete, to-day it is advised as being beneficial in some cases. In those older works calomel was advised in large doses in certain cases, later small doses only were advised. We find in Hare's "Practice," page 248, "treatment of intermittent fever": "It is, therefore, essential in almost every case (I find it essential in every case) of intermittent fever that the bowels shall be thoroughly unloaded, preferably by full doses of calomel, of which not less than 5 nor more than 20 grains are required, this in turn being followed by a saline purge." Experience and observation during an active practice of over 30 years in the malarial sections of Tennessee and Mississippi lead me seriously to doubt the anopheles mosquito or any other mosquito as being the only means by which the human system can be infected with malarial poison. Verily the pendulum does swing; therefore, it is not impossible that those old books may be useful later; at all events in this "neck of the woods" we have plenty of fuel without "burning the books." H. C. Buck, M.D.

Association News

The Constituent Branch of the American Medical Association for New York.

All legal and other details for the amalgamation of the New York State Medical Association having been completed, and the constitutional requirements for becoming the constituent branch of the American Medical Association having been fulfilled by the reorganized Medical Society of the State of New York, the following letters have been sent to the executive officers of the society by the corresponding officers of the American Medical Association:

Louisville, Ky., Dec. 22, 1905.

Dr. Joseph D. Bryant, President of the Medical Society of the State of New York, New York, N. Y.

Dear Doctor: I have the honor to acknowledge your communication conveying official notice that the final details of procedure in the consolidation of the New York State Medical Association and the Medical Society of the State of New York have been completed. I beg to congratulate you on this consummation, which has been long desired by the profession of the United States. Since the organization formed by the union of these two societies becomes the constituent branch of the American Medical Association in the state of New York, I beg to extend, in behalf of the American Medical Association, a cordial greeting to your Society and a welcome to the councils of an united profession.

With much respect, I am

Very sincerely yours,

Lewis S. McMurtry,

President of the American Medical Association.

Chicago, Ill., Dec. 24, 1905.

Dr. F. C. Curtis, Secretary, Medical Society of the State of New York, Albany, N. Y.

Dear Doctor Curtis: Since all details have been completed for the amalgamation of the New York State Medical Association with the Medical Society of the State of New York, and since the constitution of the American Medical Association regarding constituent branches has been complied with, the society of which you have been secretary for so many years is now the constituent branch of the American Medical Association for the state of New York.

I wish to take this opportunity to congratulate you, and the medical profession of New York and of the whole country, on this union. I sincerely hope that the results of this consolidation will prove not only a united profession in name, but a united profession in fact, one that will work together for the best interests of the public, of the medical profession, and of each individual member of the profession in the Empire State.

With the compliments of the season, I am,

Very truly yours,

George H. Simmons,

General Secretary, American Medical Association.

Queries and Minor Notes

NO STATES ACCEPT NEW YORK CERTIFICATES.

Rock Rapids, Iowa, Dec. 20, 1905.

To the Editor:—Please inform me through The Journal what state boards of registration, if any, accept the license of the New York State Board without further examination. Inquirer.

Ans.—No states at present. New Jersey will after Jan. 1, 1906.

INFECTION WITH RAT-TAILED LARVA OF DRONE FLY.

Carbondale, Ill., Dec. 14, 1905.

To the Editor:—In The Journal, December 9, p. 1800, the account of this case by Dr. Hanby is interesting as the second case on record of this parasite. In the November number of the *Alkaloidal Clinic* for 1900, vol, vii, p. 879, under the heading "Fly Larvæ in Bowels" was published over my name, the first and only notice I have seen of this condition before last week. A number of these larvæ were sent me by Dr. Littell for identification. After writing the brief notice referred to I bred one of the larvæ to the imago. and found it to be *Eristalis tenax*, as I had surmised. I had bred this fly from spring water before and wrote Dr. Littell that if he would look after the drinking water of his patient he would have no further trouble in that line. It may be of interest to note that I had also larvæ of a sarcophagus fly as human parasites from the same physician. G. H. French, A. M.

State Boards of Registration

COMING EXAMINATIONS.

Utah State Board of Medical Examiners, Salt Lake City, January 1. Secretary, [illegible] W. Fisher, Salt Lake City.

Arizona Board of Medical Examiners, Phoenix, January, 1-2. Secretary, Ancil Martin, Phoenix.

Washington State Medical Examining Board, Spokane, January 2. Secretary, C. W. Sharples, Seattle.

Oregon State Board of Medical Examiners (Regular), Portland, January 2. Secretary, Byron E. Miller, Portland.

North Dakota State Medical Examining Board, Grand Forks, January 2. Secretary, H. M. Wheeler, Grand Forks.

Minnesota State Board of Medical Examiners, Old Capitol Building, St. Paul, January 2-4. Secretary, C. J. Ringnell, Minneapolis.

Rhode Island State Board of Health, State House, Providence, January 4-5. Secretary, G. T. Swarts, Providence.

Arkansas Medical Board, Little Rock, January 9. Secretary, J. P. Runyan, Little Rock.

New Hampshire State Board of Medical Examiners, State House, Concord, January 9-10. Secretary, H. C. Morrison, Concord.

Vermont State Board of Medical Registration, Montpelier, January 9-11. Secretary, W. S. Nay, Underhill.

Wisconsin Board of Medical Examiners, Pfister Hotel, Milwaukee, January 9-11. Secretary J. V. Stevens, Jefferson.

South Dakota Board of Medical Examiners, Sioux Falls, January 10-11. Secretary, H. E. McNutt, Aberdeen.

District of Columbia Board of Medical Supervisors, Washington, January 11. Secretary, W. C. Woodward, Washington.

Illinois State Board of Health, Great Northern Hotel, Chicago, January 18-20. Secretary, J. A. Egan, Springfield.

New York State Boards of Medical Examiners, January 30-February 2. Secretary, Charles F. Wheelock, Albany.

Vermont Change in Place of Examination.—The place of meeting of the Vermont State Board of Medical Registration will be Montpelier instead of Burlington, Jan. 9-11, 1906.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending December 23:

Davis, Wm. B., deputy surgeon-general, will proceed to Vancouver Barracks, Washington, for temporary duty as chief surgeon, Department of the Columbia.

Flagg, Chas. E. B., asst.-surgeon, will proceed to Vancouver Barracks, Washington, for duty.

Brownlee, Charles Y., asst.-surgeon, will proceed to Alcatraz Island, Cal., for duty.

Grissinger, Jay W., asst.-surgeon, will proceed to Fort Jay, N. Y., for duty.

Talbott, Edward M., asst.-surgeon, will proceed to Fort Leavenworth, Kans., for duty.

Clark, John A., asst.-surgeon, will proceed to Fort Oglethorpe, Ga., for duty.

Coffin, Jacob M., asst.-surgeon, will proceed to the Army and Navy General Hospital, Hot Springs, Ark., for duty.

Fife, James D., asst.-surgeon, will proceed to Fort Slocum, N. Y., for duty.

Powell, Wm. A., asst.-surgeon, will proceed to Jefferson Barracks, Mo., for duty.

Kilbourne, E. D., asst.-surgeon, will proceed to Army General Hospital, Presidio of San Francisco, Cal., for duty.

Foster, Charles L., asst.-surgeon, assigned to duty in the U. S. Transport service and will report in person to the medical superintendent of that service in San Francisco, Cal., for duty.

Smith, Herbert M., asst.-surgeon, relieved from duty at Army General Hospital, Presidio of San Francisco, Cal., and ordered to Fort Apache, Ariz., for duty.

Willcox, Charles, surgeon, granted four months' leave about March 24, 1906, with permission to go beyond sea.

Lewis, Wm. F., asst.-surgeon, granted 30 days' leave of absence, to take effect on arrival at Chicago.

Lyster, Wm. J. L., asst.-surgeon, granted 15 days' leave of absence about December 18.

Marrow, Charles E., asst.-surgeon, left Fort Sheridan, Ill., on 10 days' leave of absence.

Davis, Wm. B., deputy surgeon-general, granted 30 days' leave of absence, with permission to apply for two months' extension.

Coffin, Jacob M., asst.-surgeon, granted 15 days' leave of absence.

Skinner, Geo. A., asst.-surgeon, ordered to accompany headquarters and 1st Battalion, 24th Infantry, from Fort Harrison, Mont., to Presidio of San Francisco, Cal., and thence to return to station.

Steer, Samuel L., asst.-surgeon, ordered to accompany the 2d Battalion 24th Infantry from Fort Assinniboine, Mont., to Presidio of San Francisco, Cal.

Greenleaf, H. S., asst.-surgeon, granted 16 days' leave of absence, to take effect Jan. 1, 1906.

Clark, John A., asst.-surgeon, granted 30 days' leave of absence, with permission to apply for 30 days' extension.

Dutcher, Basil H., asst.-surgeon, leave of absence extended to April 14, 1906, with permission to go beyond the sea.

Mason, George L., dental surgeon, left Fort McPherson, Ga., and arrived at Fort Fremont, S. C., for duty.

Boak, S. Davis, dental surgeon, left Fort Myer, Va., and arrived at Columbus Barracks, Ohio, for duty.

Reagles, James, contract surgeon, ordered from Fort Keogh, Mont., to Fort Yellowstone, Wyo., for temporary duty.

Casaday, George H., dental surgeon, relieved from duty in the Philippines Division, and will sail on first transport after Feb. 1, 1906, for San Francisco, Cal.

Bernheim, Julien R., dental surgeon ordered from Fort Porter, N. Y., to Plattsburg Barracks, N. Y., for duty.

Wing, Franklin F., dental surgeon, ordered from Jefferson Barracks, Mo., to Fort Riley, Kans., for duty.

Ware, William H., dental surgeon, granted leave of absence for two months from Fort Logan, Colo.

Jones, George H., contract surgeon, relieved from duty at Fort Fremont, S. C., and ordered to duty at Fort Moultrie, S. C.

Thorp, Charles W., contract surgeon, left Fort Ethan Allen, Vt., on leave of absence for one month.

Byars, Caspar R., contract surgeon, left Fort Sam Houston, Texas, and arrived at Fort McIntosh, Texas, for temporary duty.

Merrick, John N., contract surgeon, ordered to accompany troops from Fort Missoula, Mont., to San Francisco, Cal.

Stuckey, Harrison W., contract surgeon, ordered to Fort Snelling, Minn., to Fort Assinniboine, Mont., for temporary duty.

Mount, James R., contract surgeon, arrived at San Francisco on the transport *Thomas* on three months' leave of absence, from the Philippines Division.

Leeper, John F., contract surgeon, arrived at San Francisco, Cal., on the transport *Thomas* on two months' leave of absence from the Philippines Division.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending December 23:

Ransdell, R. C., asst.-surgeon, ordered to Naval Hospital, Newport, R. I., December 16.

Richardson, F. A., acting asst.-surgeon, detached from naval recruiting station, Baltimore, Md., and ordered to duty with naval recruiting party No. 3, Hutchinson, Kans., January 2.

Duncan, G. F., acting asst.-surgeon, detached from naval recruiting party No. 3, Wichita, Kans., and ordered home and granted leave until January 23.

Diehl, O., surgeon, ordered to *Lancaster*, December 19.

Riggs, C. E., surgeon, ordered to naval medical supply depot, navy yard.

Michels, R. H., asst.-surgeon, New York, ordered to naval recruiting station, St. Louis, Mo.

Riggs, R. E., asst.-surgeon, detached from *Franklin*, December 26, and ordered to command naval hospital, Port Royal, S. C.

Blackburn, T. C., acting asst.-surgeon, detached from naval recruiting station, St. Louis, Mo., and ordered to *Franklin*.

Keene, W. P., acting asst.-surgeon, detached from naval hospital, Port Royal, S. C., ordered home and granted leave until expiration of appointment as acting assistant surgeon.

De Valin, C. M., surgeon, detached from *Lancaster* and ordered to naval recruiting station, Baltimore, Md.

Schwerin, L. H., acting asst.-surgeon, detached from *Hancock* and ordered to *Yankton*, January 3.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending December 20:

Irwin, Fairfax, surgeon, granted leave of absence for five days from December 26.

Carmichael, D. A., surgeon, on being relieved by Asst. Surg. W. C. Rucker, directed to proceed to Buffalo, N. Y., and assume command of the service at that port.

Carrington, F. M., surgeon, leave of absence granted for seven days from December 14, amended to read four days only.

Oakley, J. H., P. A. surgeon, granted leave of absence for one day.

Kerr, J. W., P. A. surgeon, assigned to duty at the Bureau, Washington, D. C.

Holt, J. M., P. A. surgeon, relieved from temporary command of the service at San Francisco, Cal., and directed to report to Surgeon H. W. Sawtelle for duty.

Warren, B. S., P. A. surgeon, expiration of present leave status, relieved from duty at Cape Fear Quarantine Station and directed to proceed to Boston, Mass., reporting to the medical officer in command for duty and assignment to quarters.

[illegible] asst.-surgeon, granted leave of absence for five [illegible] 24.

[illegible] sst.-surgeon, granted leave of absence for one [illegible] er 22.

Rucker, W. C., asst.-surgeon, relieved from duty at Boston, Mass., and directed to proceed to Vineyard Haven, Mass., assuming temporary command of the service at that port and relieving Surgeon D. A. Carmichael.

Foster, S. B., A. A. surgeon, granted leave of absence for ten days from December 12.

Holsendorf, B. E., pharmacist, granted one day's leave of absence under paragraph 210 of the Regulations.

BOARD CONVENED.

Board convened to meet at the Marine Hospital, San Francisco, Cal., Dec. 22, 1905, for the purpose of conducting a medical survey of an officer of the Revenue Cutter Service. Detail for the board: P. A. Surgeon Hugh S. Cumming, Chairman; P. A. Surgeon J. M. Holt, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon-general, Public Health and Marine-Hospital Service, during the week ended December 22:

SMALLPOX—UNITED STATES.

California: Los Angeles, Dec. 2-9, 4 cases; San Francisco, Nov. 25-Dec. 2, 5 cases.

Illinois: Galesburg, Dec. 9-16, 1 case.

Kentucky: Covington, Dec. 9-16, 1 case.

Maryland: Baltimore, Dec. 9-16, 1 case.

Michigan: Gratiot County, Nov. 1-30, 1 case.

Washington: Spokane, Nov. 1-30, 1 case.

SMALLPOX—FOREIGN.

Brazil: Bahia, Oct. 28-Nov. 25, 99 cases, 5 deaths; Pernambuco, Nov. 1-15, 43 deaths; Rio de Janeiro, Oct. 22-Nov. 19, 29 cases, 12 deaths.

Canada: Toronto, Nov. 25-Dec. 9, 5 cases.

Chile: Antofagasta, Oct. 24-Nov. 7, 48 cases, 13 deaths; Coquimbo, Oct. 22-Nov. 4, 17 cases, 4 deaths; Iquique, Oct. 26-Nov. 9, 20 cases, 22 deaths.

Ecuador: Guayaquil, Nov. 19 26, 5 deaths.

France: Paris, Nov. 25-Dec. 2, 22 cases.

Great Britain: Plymouth, Nov. 25-Dec. 2, 6 cases.

India: Calcutta, Nov. 4-11, 1 death; Karachi, Nov. 4-19, 2 cases, 1 death.; Madras, Nov. 11-17, 2 deaths.

Italy: General, Nov. 16-30, 23 cases.

Mexico: City of Mexico, Nov. 18-Dec. 2, 7 cases, 4 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Oct. 22-Nov. 19, 20 cases, 6 deaths.

Cuba: Habana, Oct. 16-Dec. 15, 60 cases, 14 deaths; Matanzas Province, Dec. 8-17, 7 cases, 1 death; Santa Clara Province, Dec. 5, 1 case.

Ecuador: Guayaquil, Nov. 18-26, 3 deaths.

Honduras: Choloma, Nov. 15-21, 2 cases, 1 death; Puerto Cortez, 2 cases, 1 death; San Pedro, 4 cases, 1 death.

Mexico: Coatzocoalcos, Dec. 2-9, 1 case, 1 death; City of Mexico, Nov. 25-Dec. 2, 1 case, 1 death.

CHOLERA—FOREIGN.

India: Calcutta, Nov. 4-11, 33 deaths; Madras, Nov. 11-17, 12 deaths.

PLAGUE—FOREIGN.

Brazil: Bahia, Dec. 15, 5 cases, 3 deaths; Pernambuco, Nov. 1-15, 5 deaths.

India: Calcutta, Nov. 4-11, 21 deaths; Karachi, Nov. 5-19, 10 cases, 10 deaths.

Japan: Kobe, Nov. 8-15, 7 cases; Osaka, Oct. 21-Nov. 15, 18 cases, 14 deaths.

Mauritius: Nov. 2-16, 23 cases, 13 deaths.

Peru: Callao, Oct. 11-31, 1 case, 1 death; Chiclavo, 1 case, 6 deaths; Lima, 8 cases, 1 death; Mollendo, 1 case, 28 deaths.

Rio de Janeiro: Rio de Janeiro, Oct. 22-Nov. 19, 48 cases, 17 deaths; Sao Paulo, Oct. 15-22, 1 death.

Zanzibar: Oct. 8-21, 37 cases, 21 deaths.

Medical Organization

WHAT A COUNTY SOCIETY MAY DO.

The following letter from one of the leading surgeons of Indiana contains so much of interest to county societies, indicating as it does what may be done in any section where as many as three or four wide-awake men can be gotten together, that we are glad of the opportunity to put it before the profession. "What one man has done, other men can do."

Valparaiso, Ind., Dec. 21, 1905.

Dr. J. N. McCormack, Chairman Committee on Organization, Bowling Green, Ky.

My Dear Doctor: Your letter asking me to elaborate our plan of postgraduate work here, with the view that such an account may be used in inducing other medical societies to do likewise, has been received.

I am greatly pleased to have the privilege of doing this, not only for your personal gratification, but because I am confident that it will redound to the very great benefit of such societies as may deem it wise to adopt our plan, as well as to the individual members. It will enable them to do better and more efficient work for the public as a whole, and will aid each individual physician in rendering the best possible service to the unfortunate sick.

Our work was begun two years ago by getting every physician interested in becoming more familiar with scientific and practical knowledge which would be of advantage to him at the bedside, and which would broaden him as a physician. With this end in view, we rented a room, formed a club, and endeavored in every way to appeal to and to build up the social, scientific and material spirit and welfare of the profession. From every point of view I desire to report that we have been eminently successful.

In carrying out this plan we divided our work in such a way that each physician was required to act as a teacher of some special subject, and all the others took their places as students once more. Anatomy and surgery were assigned to one, physiology and practice to another, and so on through the list of subjects, one fundamental and one practical branch being allotted to each teacher. Our meetings were held twice a week, regular lessons were assigned, and we were expected to be present and to give one hour's time to the recitation and study of the subject for the evening's work. In this way we were enabled not only to exchange our individual views as to what we believed, but could always have some good medical authority to place us right if it was found that we were wrong. This plan proved very satisfactory, and we soon learned that the physician who was teacher of the topic assigned derived far greater benefit from his course, for the reason that he was required to study more to hold his ground, sometimes against the combined opinions of the members of his class.

After going along in this way for a time it soon became apparent that the general good demanded that our faculty should be changed from time to time, in order that the teachers could become proficient in more than one subject. I desire to report to you that we found this plan most satisfactory and that it has resulted in a marked improvement of the professional attainments of every individual member of our profession, which means, of course, of the profession as a whole.

The social feature of our plan has done as much, if not more, for the general good of the profession, as the scientific work, and I am now able to report to you that we have no one in this county not on the most friendly terms with the others, and that this is not because they have to be friendly, but because they actually desire to be friendly.

In connection with this work our county society has kept up its regular meetings, always with increased interest, until to-day, although ours is not one of the large counties, I believe I can honestly report to you that we have one of the best, if not the best, county medical society in the state of Indiana, and we are resolved to go on and to keep it well to the front.

It did not take us long to determine that in consideration of the increase in the cost of living in recent years our services were inadequately paid for, and we concluded it was nothing but justice that the general scale of prices should be increased one-half. In order that this might be uniformly done, we each signed a schedule of fees and caused this to be published, with the signatures of every physician in the city attached, definitely fixing the prices of services during the day, and also during the night. The new schedule went into effect without a single ripple, and it has been strictly maintained. I have never known any complaint on the part of the public, or of the agreement being violated by any member of our profession. The public seemed to understand the necessity for the change of schedule, largely because it knew our profession was making a heroic effort to give the people better service. The results have been that our physicians are paid one-half more for their services and the night work has been reduced to a minimum, giving us the evenings for postgraduate work and to spend with our families.

While we have not accomplished all that we set out to do, we have certainly made rapid progress, and are still determined to go on in the same way and never to stop or to falter until our ideals are attained.

Probably this very crude plan might be radically elaborated and improved with benefit, but it has worked so well, and has given such universal satisfaction, that I think none of our profession would be willing to disturb our present satisfactory condition.

Should you in your work be able to use what we have done as an incentive for others to do likewise, or to elaborate it in any way for the promotion of medical organizations, I am sure that you will have the very best wishes of every member of our profession here in your work.

With personal best wishes, I am, most sincerely yours,

David J. Loring, M.D.

Marriages

Milton M. Hess, M.D., to Mrs. Sarah King, both of Morristown, Ind., November 27.

Howard V. Dutrow, M.D., to Miss Emma Agnes Thomas, at Frederick, Md., December 14.

Donald B. Frederick, M.D., Atlanta, Ga., to Miss May King of Marshallville, Ga., December 27.

Ellet Orrin Sisson, M.D., Denver, Colo., to Miss Maze Vernon of Keokuk, Iowa, December 27.

Carroll Flippin, M.D., Charlottesville, Va., to Miss Isabel Anderson of Auburn, Ala., December 19.

Herbert E. Zepp, M.D., St. Michael's, Md., to Miss Grace L. Northam, at Kegotank, Va., December 6.

William G. Reeder, M.D., to Miss Maude Van Heusen, formerly of St. Louis, recently of Chicago.

Peyton R. Denman, M.D., Lufkin, Texas, to Miss Frances Wootters of Crockett, Texas, December 5.

Robert E. Davison, M.D., Pittsburg, Pa., to Miss Nettie May Kratzer of Glenfield, Pa., December 20.

Joseph Harold Holt, M.D., Sherman, Texas, to Miss Norma Lucile Strickland of Athens, Ga., November 8.

Frederick Green Barfield, M.D., Cuthbert, Ga., to Mrs. Helen Denham of Jacksonville, Fla., November 29.

Charles Preston Eichelberger, M.D., to Miss Mary Alexandria Arrington, both of Danville, Va., December 20.

Charles Henry Conley, M.D., Adamstown, Md., to Miss Helen Abell Baughman of Frederick, Md., December 12.

Thomas Stringfield, M.D., Waynesville, N. C., to Miss Mary Elizabeth Moore of Birmingham, Ala., December 26.

Harold Capron Bailey, M.D., to Miss Sarah Pauline Kennedy, both of Buffalo, N. Y., at Brooklyn, N. Y., December 15.

Otto Charles Quitmeyer, M.D., Parker's Prairie, Minn., to Miss Jean Elizabeth McEwan of Alexandria, Minn., December 12.

Charles Thompson Chamberlain, M.D., Portland, Ore., to Miss Deborah Boatner of Vidalia, La., at Natchez, Miss., November 29.

Marion F. Marvin, M.D., acting assistant surgeon, United States Army, to Miss Ella Constance Johnson of South Carolina, at Chadron, Neb., December 12.

Deaths

William Josiah McMurray, M.D. University of Nashville Medical Department, 1869; president of the Tennessee State Board of Health; a veteran of the Civil War, in which he lost his left arm; member of the Tennessee State Medical Association, Nashville Academy of Medicine and Royal Anthropological Society of London; physician of Davidson County in 1872; alderman of Nashville in 1876; one of the most prominent practitioners of Nashville, died at his home in that city, December 4, from pneumonia, after an illness of one week, aged 63.

Daniel Maxon Cool, M.D. Rush Medical College, Chicago, 1861; for several years professor of diseases of children in the Chicago Medical College; surgeon of the Third Iowa Volunteer Infantry during the Civil War; some-time member of the American Medical Association, Minnesota State Medical Society, and Rice County Medical Society; for nine years health commissioner and for many years city physician of Faribault, Minn., died at his home in that city, December 14, from heart disease, after a long period of invalidism, aged 82.

Nathan Bozeman, M.D. University of Louisville Medical Department, 1848; formerly of Mason, Ga.; a surgeon in the Confederate service during the Civil War; for many years proprietor of a hospital in New Orleans, died at his home in New York City, from cerebral hemorrhage, December 16, after an illness of one week, aged 80. His contributions to the literature and armamentarium of gynecology were numerous and valuable.

Hiram N. Rucker, M.D. University of California Medical Department (Toland Medical College), San Francisco, 1870; resident physician and superintendent of the Masonic Widows and Orphans' Home, Decoto, Cal.; a member of the American Medical Association; formerly superintendent of the Stockton State Hospital, and of the Soldiers' Home of Yountville; for a time health officer of Oakland, was run over and instantly killed by a train at Decoto, December 13, aged 55.

Colonel Cyrus Tracy Peckham M.D. Harvard University Medical School, Boston, 1879; assistant surgeon general United States Public Health and Marine-Hospital Service, stationed at Buffalo, N. Y., died at his apartment in the Markeen, in that city, December 10, from cerebral hemorrhage, after an illness of two days, aged 52. Colonel Peckham's most notable services were in the study of malaria and trachoma, and in the care of the afflicted in Galveston, after the flood.

Richard H. Tullis, M.D. Northwestern University Medical School, Chicago, 1890; a member of the American Medical Association and of the national auxiliary legislative committee in 1904-5, and president of the Oklahoma State Medical Association; one of the most prominent physicians of the Southwest, died at his home in Lawton, Okla., December 12, from typhoid fever, after an illness of ten days, aged 41.

Gustav Adolph Prieson, M.D. University of Würzburg, Germany, 1852; assistant surgeon of the Sixth Pennsylvania Volunteer Cavalry and surgeon of the Thirty-eighth Pennsylvania Emergency Militia; local surgeon to the Pennsylvania System; some-time coroner and sheriff of Clinton County, Pa., died at his home in Lock Haven, from nephritis, December 2, after an illness of eight weeks, aged 73.

Albert Thompson, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1864; assistant surgeon and surgeon of the Third Michigan Volunteer Cavalry; for two years state senator; for several years a practitioner of Colton, Cal., and mayor of that city, died at his home in Danbury, Conn., November 22, after a long illness, from heart disease, aged 74.

Lafayette O'Mahoney, M.D. St. Louis College of Physicians and Surgeons, 1896, of Columbia, Mo., who was crushed between a train and a station wall in August of last year, necessitating the amputation of both legs, died from tuberculosis at Denison, Texas, December 13, after a lingering illness, aged 32.

Putnam S. Fulkerson, M.D. Jefferson Medical College, Philadelphia, 1854; collector of Lafayette County, Mo., from 1876 to 1881; postmaster of Lexington for four years, and president of the Lafayette County Medical Association, died at his home in Lexington, December 16, after a short illness, aged 80.

William Pfisterer, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1890, for three years a practitioner in Minnesota and thereafter an invalid from paralysis, dropsy and mental disease, died at the home of his sister in New Ulm, Minn., November 23, aged 40.

Augustus Louis Jukes, M.D. Trinity Medical College, Toronto, 1865; College of Physicians and Surgeons of Ontario, Toronto, 1866; senior surgeon of the Northwest mounted police in 1882, and member of the Board of Medical Examiners of the Northwest Territories in 1886, died recently in Vancouver, B. C., aged 84.

James Elliott, M.D. New York University, New York City, 1850; said to have been the oldest practitioner of Newark, N. J.; one of the founders of St. Michael's Hospital, and for many years a member of its staff, died at his home in Newark, December 15, from senile debility, aged 88.

J. Edwin Hughes, M.D. College of Physicians and Surgeons. Keokuk, Iowa, 1876, of Almira, Wash., after confinement in the Yakima County jail for several months on charges of rape and bigamy, committed suicide, December 8, by hanging himself with a towel, from a bunk-hook.

Benjamin W. Inman, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1885, a member of the Mississippi State Medical Association, and of the Washington County Medical Society, died at his home in Leota Landing, Miss., December 11, from nephritis.

James M. Ely, M.D. Medical College of Indiana, Indianapolis, 1878; for more than 60 years a practitioner of Indiana; the oldest practitioner in Hancock County, died at his home in New Palestine, December 11, from senile debility, after an illness of nine months, aged 84.

Joseph D. Searles, M.D. County License (Huntington County, Ind.) 1897; secretary of the Huntington County Board of Health, and health officer of Huntington; for 43 years a practitioner of that city died suddenly at his home, December 2, from heart disease, aged 69.

William Joshua Arnott, M.D., C.M. Trinity Medical College, Toronto, 1893; surgeon to the Berlin and Waterloo (Ont.) hospitals; medical health officer of Berlin, and coroner of Waterloo County, died from meningitis at his home in Berlin, Ont., December 12, aged 43.

Henry Irvin Jones, M.D. University of Nashville Medical Department, 1904, a member of the Kentucky State Medical Society and the Monroe County Medical Society, died at his home near Martinsburg, Ky., from tuberculosis, after an illness of several months, aged 23.

James E. Kelsey, M.D. College of Physicians and Surgeons of Syracuse (N. Y.) University, 1873; for several years health officer of Theresa, N. Y., and at one time state health officer, died at his home in Theresa, December 10, from nephritis, after a long illness, aged 55.

William Wallace Gardner, M.D. New York University, New York City, 1865; for many years a member of the Massachusetts Medical Society; a veteran of the Mexican War, died at his home in Springfield, Mass., December 11, from senile debility, aged 79.

James M. Waddick, M.D. Miami Medical College, Cincinnati, 1868; a veteran of the Civil War; for many years connected with the Boys' Industrial Home, Toledo, Ohio, died suddenly at his home in that city, December 12, from heart disease, aged 68.

J. M. Mitchell, M.D. Memphis (Tenn.) Hospital Medical College, 1858; for four terms a member of the Tennessee legislature, and one of the most prominent practitioners of western Tennessee, died at his home in Michie, December 11, aged 72.

Charles William Jones, M.D. Cooper Medical College, San Francisco, 1891, formerly of Grass Valley, Cal., died in St. Luke's Hospital, San Francisco, from the effects of carbolic acid taken with suicidal intent, December 9, aged 36.

Charles Herbert Osborne, M.D. Bellevue Hospital Medical College, New York City, 1880, traveler and linguist, died at the residence of his sister in Newark, N. J., December 9, after an illness of ten days, from diabetes, aged 52.

Thomas Gibson, M.D. Medical College of Georgia, Augusta, 1840, one of the most widely known physicians of Georgia, died on his plantation in Twiggs County, near Macon, December 11, after an illness of several months, aged 86.

Thomas J. Hourigan, M.D. Kentucky School of Medicine, Louisville, 1898, of Gravel Switch, Ky., died at the Gray Street Infirmary, Louisville, December 12, four days after an operation for peritoneal tuberculosis, aged 40.

Clarence E. Sturgeon, M.D. College of Physicians and Surgeons of Chicago, 1905, interne at Hackley Hospital, Muskegon, Mich., died from mediastinal sarcoma, at his home in Clarion, Iowa, after an illness of nine weeks.

David O. Holmes, M.D. Memphis Hospital Medical College, 1890, formerly of Swan Lake, Ark., and Memphis, Tenn., died at Asheville, N. C., December 12, after a long illness, from tuberculosis, aged 36.

Charles W. Keyes, M.D. Howard University Medical Department, Washington, D. C., 1890, died at his home in Washington, D. C., December 19, from cerebral hemorrhage, after an illness of two days, aged 51.

Wellman M. Burbank, M.D. Castleton (Vt.) Medical College, 1844, one of the oldest practitioners of Chicago, died from senile debility at his home, December 20, after an illness of several weeks, aged 81.

George W. Ellinger, M.D. Jefferson Medical College, Philadelphia, 1878; once physician of Shawnee County, Kan., died at his home in Topeka, December 10, from paralysis, after an illness of several months.

B. F. Trabue, M.D. University of Louisville (Ky.) Medical Department, 1850, said to have been the oldest practitioner of Barren County, Ky., died suddenly at his home in Glasgow, November 29, aged 83.

William Wallace Senteny, M.D. Medical College of Ohio, Cincinnati, 1840, died at his home in Louisville, Ky., December 7, from senile debility, hastened by a fracture of the hip two years ago, aged 87.

Granville I. Leavitt, M.D. Toland Medical College, San Francisco, 1866, who had served in both houses of the Nevada legislature, died at his home in Mason Valley, the first week in December, aged 76.

William Postlethwaite, M.D. University of Louisville (Ky.) Medical Department, 1850, died at his home in Chanute, Kan., November 23, from senile debility, after an illness of three weeks, aged 87.

Alexander B. McKinnon, M.D. New York University, New York City, 1886, a member of the American Medical Association, died from diabetes at his home in Fairhaven, Bellingham, Wash., aged 58.

John M. Wilkins, M.D. University of Nashville (Tenn.) Medical Department, 1878, one of the oldest practitioners of Vermilion County, Ill., died at his home in Fairmount, December 1, aged 80.

T. A. York, M.D. Medical Department University of Tennessee, Nashville, 1886, died at his home in Greenbrier, Tenn., December 13, from paralysis, after an illness of more than a year, aged 59.

William Geddes Stark, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1877, formerly a practitioner of Hamilton, Ont., died at his home in Philadelphia, December 12.

James B. Edge, M.D. Atlanta (Ga.) Medical College, 1880, a well-known practitioner of South Georgia, died in his apartment at Cordele, December 14, after a brief illness, aged 43.

Henry C. Bowen, M.D. Ohio, 1854, for more than half a century a practitioner of Cleveland, died at his home in that city, December 13, after an illness of three years, aged 86.

John J. Smythe, M.D. Trinity College, Dublin, 185—; a fenian leader; some-time coroner of Luzerne County, Pa., died suddenly in Scranton, Pa., December 1, aged 73.

Euphrates W. Rudolph, M.D. University of Louisville (Ky.) Medical Department, 1890, died at his home in Tonkawa, Okla., November 24, from pneumonia, aged 40.

John J. Mullen, M.D. Dartmouth Medical School, Hanover, N. H., 1888, died at his home in Portsmouth, N. H., December 16, after an illness of several months, aged 42.

Moses M. Frye, M.D. Pennsylvania, 1870, of Auburn, N. Y., died at a sanitarium in Rochester, N. Y., from pulmonary tuberculosis, after a long illness, December 14.

Daniel Thurston Plumer, M.D. Harvard University Medical School, Boston, 1842, died at his home in Newburyport, Mass., December 3, from pneumonia, aged 86.

William H. Kinney, M.D. Detroit (Mich.) Medical College, 1879, of Detroit, died suddenly from cerebral hemorrhage in a coal office in Detroit, December 11, aged 52.

James E. Thomson, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1901, died at his home in Delhi, La., November 30, from appendicitis.

Maurice K. Dwinell, M.D. Massachusetts, 1883, formerly a practitioner of Waterville, Maine, died at the Maine Insane Hospital, Augusta, December 15, aged 46.

John S. M. Pride, M.D. University of Nashville Medical Department, 1862, died at his home in Culleoka, Tenn., December 2, after a protracted illness, aged 71.

F. Saxenberger, M.D. University of Leipzig, Germany, 1865, died at his home in Beatrice, Neb., from dropsy, December 15, after an illness of several years, aged 65.

Charles Ed Smith, M.D. Years of Practice, Illinois, 1887, one of the oldest practitioners of Macoupin County, Ill., died recently at his home in Palmyra, Ill.

Joseph C. Sparks, M.D. Medical College of Ohio, Cincinnati, 1853, was found dead in his home in Wyoming, Ohio, December 15, from heart disease, aged 77.

Andrew H. Gillmore, M.D. Medical College of Ohio, Cincinnati, 1855, of Terre Haute, Ind., died at the home of his daughter, in that city, December 10.

Benjamin Franklin Stevens, M.D. St. Louis, 1874, a veteran of the Civil War, died at his home in St. Jacob, Ill., December 9, from senile debility, aged 74.

Jerome Smith, M.D. Louisville Medical College, 1870, died at his home near Hodgenville, Ky., December 10, after an illness of several months, aged 74.

Sylvester Thompson, M.D. Rush Medical College, Chicago, 1885, died at his home in Galva, Ill., November 28, from pneumonia, after a short illness.

Daniel Walters, M.D. Long Island College Hospital, Brooklyn, 1897, died at his home in Wharton, N. J., December 11, from typhoid fever, aged 36.

Alfred W. Hayward, M.D. Missouri, 1894, died at his home in Mound City, Kan., December 13, from malarial fever, after an illness of a few weeks.

Philip B. Knight, M.D. Detroit (Mich.) College of Medicine, 1894, died at his home in Utica, Mich., December 18, from heart disease, aged 37.

Mary J. B. Paul, M.D. Northwestern University Woman's Medical School, Chicago, 1882, died at her home in Bryan, Ohio, November 27.

C. L. Summey, M.D. Atlanta, (Ga.) Medical College, 1876, died at his home in Stone Mountain, Ga., December 10, after a long illness.

Levi Saunders, M.D. Chicago, 1880, died recently at Brunson, Mich., from cerebral hemorrhage, after an illness of one week.

Palmer Wilbur, M.D. Cincinnati, 1872, died at his home in Alden, Mich., December 7, from heart disease, aged 72.

Otis G. Randall, M.D. Philadelphia, 1878, died suddenly at his home in Bridgewater, Mass., December 7, aged 58.

Charles A. Williams, M.D. Illinois, 1861, died at the Chicago Beach Hotel, Chicago, December 18, aged 66.

Charles B. Pillsbury, M.D. Illinois, 1879, died at his home in Duluth, Minn., March 1.

Society Proceedings

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Eighteenth Annual Meeting, held in Louisville, Ky., Dec. 12-14, 1905.

(Continued from page 1977.)

Dangers from Scopolamin-Morphin Anesthesia.

Dr. Horace J. Whitacre, Cincinnati, Ohio, based his conclusions on observations made in 40 cases of anesthesia induced by this method, on animal experimentation, and on a review of all deaths that have been reported in the literature up to the present time. The author concludes: 1, That scopolamin-morphin narcosis is not devoid of danger; 2, that the use of scopolamin-morphin alone for surgical narcosis is not justifiable, and in his experience is not practicable; 3, that a single dose two hours before operation lessens the discomforts attendant on the operative procedure to a high degree, and may obtain a definite place in surgical practice; 4, that four deaths have occurred in a series of 2,400 collected cases, which have been so definitely related to the use of this method of narcosis that they are probably scopolamin deaths; this, however, in the absence of autopsy demonstration; 5, that these deaths were reported as occurring with a type picture of alkaloid poisoning, and heart failure has been given as the direct cause of death; 6, that a fatty degeneration of the liver and kidney has been produced by repeated doses of scopolamin alone, and of the scopolamin-morphin combination, in animals; 7, that this method of producing or assisting narcosis can not yet be recommended for use in general practice, in spite of the great advantage it seems to offer.

Scopolamin-Morphin-Ethyl Chlorid-Ether Anesthesia.

Dr. H. A. Royster, Raleigh, N. C., said that of all the combinations suggested for aiding and abetting these agents, that which forms the subject of his paper commends itself to him, because he believes, first, that ether is the safest general anesthetic; second, that ethyl chlorid secures the pleasantest primary narcosis; third, that the preliminary use of scopolamin with morphin increases the patient's mental resisting power and lessens the quantity of ether. In his opinion there can be no question of the superiority of ethyl chlorid over nitrous oxid gas as a preliminary to ether anesthesia. Its action is more certain and constant and equally agreeable, and he can not help feeling that it is safer. His experience in regard to the combination of morphin and scopolamin is confined solely to the use of these drugs prior to the administration of ether. Clinical tests have led him to conclude that scopolamin is not identical with hyoscin, and that it does something more than morphin alone, and that it is safe in proper doses. He warned against careless use of scopolamin, inasmuch as several deaths have followed its employment.

Fracture-Dislocation of Condyles of Femur, with Backward Luxation of Leg.

Dr. George S. Brown, Birmingham, Ala., reported the case of a patient, aged 14, who was injured in a football game, and who was treated for three months for sprained knee. A skiagraph revealed fracture-dislocation of the condyles. He walked for four months after this with bad valgus and flexion of the leg on the thigh before submitting to an operation. The limb and knee joint were restored to normal. There was bony union of the fragments in their dislocated position. Through a four-inch incision down the inner aspect of the femur, the lower end of which stopped short of the level of the knee joint, the periosteum was cut through and pushed downward, the union chiseled through, the broken surfaces resected, and the leg brought forward on the thigh without opening the joint. The fragments were wired and the internal lateral ligament closed with kangaroo tendons. The skin was closed with a subcuticular suture of silkworm gut. Owing to the first dressing being left too long, there was a superficial infection which did not interfere with the final good result.

Technic in Appendicitis Operations.

Dr. W. P. Carr, Washington, D. C., said that in this disease it was apparent that no one method of operating will suit all cases. Surgeons must modify the technic to suit the case and the strength of the patient. In his first 100 cases he had 8 deaths. In his last 72 cases he has had but 2 deaths, and he believes the improvement in mortality is due to a fuller knowledge of the condition of the patients and a suitable adjustment of the technic to those conditions. The incision should always be either the gridiron or through the rectus muscle; otherwise hernia is very liable to follow. There is but one objection to the gridiron incision, namely, it can not be greatly enlarged without cutting across the fibers of the internal oblique and transversalis muscles. This, he thinks, should never be done. It is better to close the wound and open again through the rectus muscle if a very large opening becomes necessary. However, if this incision is well placed, it may be stretched with the fingers and a fairly large opening made through which any uncomplicated operation may be done. The stretching should never be excessive, as paralysis of the stretched muscle fibers may result, and hernia follow.

Neglected Appendicitis.

Dr. Charles M. Rosser, Dallas, Texas, concedes the safety of an acutely inflamed appendix if the pathology is limited to the structures of that viscus; but the serious mortality following cases not so treated justifies a classification of those passing the initial stage as being neglected, whether the delay is due to indifference, ignorance or cowardice, and whether the responsibility is on the family, patient, or medical adviser. The safe time limit varies with the character of the attack, the skill of the operator, and the resistance of the individual. The author considered the question of whether to operate settled affirmatively; that the question of when to operate is agreed to, if early, but he proposes the question of, who shall operate, and what operation shall be done? While appendectomies are occasionally simple of performance, yet they are prospectively delicate, and the patient is entitled to the most skillful service available in each instance, and he thinks the geographical distribution of competent surgeons is sufficiently general that there is hardly an excuse for an emergency operation by the attending physician if he is not so equipped. He advises incision in all cases at all stages except those already moribund, and in which added insult to vitality will be immediately hazardous, and a class having reached adhesive protection in which a relaxed rectal orifice indicates early rupture and discharge by that route. After incision the surgeon must decide whether to remove the appendix alone, whether removal and drainage, or whether drainage alone should be the operation of election. But as exploration can best determine another indefinite pathologic progress, the patient should be given the benefit of the doubt.

Requirements and Qualifications for a Successful Career in Surgery.

The address of the president, Dr. Lewis C. Bosher, Richmond, Va., will be published in The Journal.

Overlapping Aponeuroses in Closure of Abdominal Wounds.

Dr. Charles P. Noble, Philadelphia, recommended a method of overlapping the aponeuroses which he has used with the utmost satisfaction for nine years. In but one case does he know of a postoperative hernia where the abdominal wound was closed by this method.

Starvation and Locked Bowels for About Two Weeks.

Dr. Howard A. Kelly, Baltimore, Md., offers for a more extended trial in other fields as well a method of after-treatment which he has used in some 15 cases, for the most part in complete tears of the recto-vaginal septum. The treatment consists in two parts. First, a very limited diet for from 10 to 15 days; second, the locking up of the bowels during this period. The food is limited to albumin and water, giving nothing the day following operation, and but one dram every three hours on the second day, and increasing this a dram each day until the patient is taking four drams every three hours. In this way the patient is fed during a period of 10 days not quite three pints of albumin and absolutely no other food. One patient was continued on this diet for fifteen days without an evacuation. At least two very frail patients were treated in this way. When the evacuation takes place, two drams of licorice powder are given, and in some cases an oil enema, and the passage is secured with the patient lying on her side, so as to avoid any straining. In no case are there any scybala, or is there any difficulty with the evacuations. Dr. Kelly thinks this starvation plan of treatment should have a wider range of utility in treating dyspeptics and cases of hysteria, as well as in all kinds of plastic operations on the intestinal tract.

Surgical Treatment of Cancer of the Head and Neck.

Dr. George W. Crile, Cleveland, Ohio, presented general conclusions, that since the head and neck present an exposed field, cancer here, unlike that of the stomach, the intestines or even the breast, may be recognized at its very beginning. Every case is at some time curable by complete excision. The field of regional metastasis is exceptionally accessible; that cancer rarely penetrates beyond the extraordinary lymphatic collar of the neck; that the growth tends to remain here localized, and that by freely utilizing all the modern resources of surgery, and by applying the same comprehensive block dissection, as in the radical operation for breast cancer, the final outcome in the surgical treatment of cancer of the head and neck should be not only as good, but even better than that of almost any other portion of the body.

Late Results in Treatment of Inoperable Sarcoma with Toxins of Erysipelas and Bacillus Prodigiosus.

Dr. W. B. Coley, New York City, has used these toxins since 1892. He has advocated the treatment only in inoperable sarcoma, but in view of the successful cases he believes it wise to use the injections in all cases after primary operation for sarcoma as a prophylactic against recurrence. In these cases the dose should be much smaller, just sufficient to produce a very slight reaction, and the treatment should be continued for two to three months. He also believes it wise, in practically all cases of sarcoma of the extremities, to give the patient the benefit of a trial with the mixed toxins before sacrificing the limb by amputation. This opinion is based on 12 such cases in which, as the result of this treatment, the tumor disappeared, and in 8 of the 12 cases the patients were well from three to six years afterward. Dr. Coley gave statistics showing the results in his own and others' experience.

(*To be continued.*)

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Meeting held in Baltimore, Nov. 20, 1905.

The President, Dr. W. G. McCallum, in the Chair.

Adenocarcinoma of Stomach.

Dr. Sauers showed a man 43 years old, admitted to the hospital in June complaining of pain in the umbilical area, which had grown worse since Christmas. He had had discomfort for two years, and during the last year lost forty pounds in weight. He has had six attacks of vomiting after attacks of pain and not associated with eating. He quit work in December and took no solid food for three months. The patient's color was good; abdomen was scaphoid with pigmented areas over the epigastrium from plasters. Though weak, the patient felt good except when he had attacks of pain, which were brought on by taking any solid food, and were worse in the area of the umbilicus. The bowel felt firm in the region of the splenic colon, otherwise the abdominal examination was negative. Patient was operated on by Dr. Bloodgood, June 29, the peritoneal cavity being opened by a median incision extending from ensiform to below the umbilicus. A carcinomatous growth was found on the lesser curvature of a moderately dilated stomach 3 cm. below the pylorus. Practically all the lesser curvature was removed, together with an adjacent gland showing metastasis. All the fat was removed with the lesser curvature, and adhesions binding the stomach to the pancreas were broken up, showing an area of induration in the central portion of the pancreas. The duodenal and stomach ends were reinforced, a loop of the duodenum being anastomosed to the posterior wall of the stomach. The pancreas was left intact, an inflammatory induration of the pancreas, in cancer of the stomach, not indicating removal as a cancerous involvement would. Patient left the hospital on July 30, and has since gained 32 pounds in weight. He has had no vomiting or pain, and bowels are regular. After a test meal of 100 c.c., 12 c.c. were gotten an hour later. Pathologically the tumor, which was a large fungous mass on the lesser curvature of the stomach, reaching to within 3 c.c. of pylorus, was an adenocarcinoma.

Congenital Stenosis of the Pylorus.

Dr. Charles S. Scudder, Boston, said that until recently cases of congenital stenosis of the pylorus have been seldom recognized. The disease has been almost universally fatal. The first case reported was by Beardsley of New Haven in 1788. A case was reported in 1841 and a case in 1842. These were the only two reported during the 100 years between Beardsley's report in 1788 and Kirschbaum's in 1888. Since 1888 there have been 35 autopsies, with findings both definite and constant. Dr. Scudder discussed in detail the clinical history and treatment of this affection.

Relation of Dilatation of the Duodenum to Gastric Disturbances.

Dr. J. M. T. Finney said that five or six years ago on opening the abdomen for a variety of conditions, particularly conditions of the stomach, duodenum and gall bladder, a condition was found which was not mentioned in the literature, i. e., a dilatation of the duodenum with a patent condition of the pylorus. At that time pyloroplasty was done for want of something better. The patients gave a history of indigestion for months or years, of nausea and vomiting, and symptoms that were indefinite but distressing. Most of the patients had had medical treatment without results. In all the cases there was Glenard's disease. The condition presented by the patients was unsatisfactory for operation. When these cases were first noticed gastroenterostomy was in its infancy. Nothing that was done seemed to benefit the condition. The nearest to a description of the condition was a paper read by A. J. Ochsner in San Francisco this year, in which he reports 14 cases. Mayo, in a recent article on stomach diseases, refers to this condition. He says it is associated with enteroptosis, but does not say what to do for it.

Autopsies on 46 postoperative cases, only one of which was recognized clinically, have been reported from Vienna. The duodenum passes behind the superior mesenteric vessels, the superior mesentery itself running down to the right iliac fossa. When the stomach is much dilated, filled with fluid and has descended to the pelvis, there is a dragging on the mesentery and vessels. This is apparently one obstruction. To the proximal side the intestine is dilated, and at the distal side it is collapsed. Rokitansky in the fifties suggested that this condition might happen. Glenard also suggests that dragging on the mesentery might obstruct the duodenum. In 4 of the 46 Vienna cases the stomach was not markedly dilated, though in most of the cases it had descended. The explanation is not satisfactory for the condition. The dilatation is the effect, not the cause, though it may be both. Two cases have been reported after operations other than abdominal, one being a breast removal and the other an operation on the elbow. Schnitzler suggests that it takes place after anesthesias, particularly after chloroform. Only one case was diagnosed before autopsy.

The treatment is postural. Put the patient in the knee-chest position for fifteen minutes every two hours or have her lie on the left side with hips elevated. Lavage has been tried with some success. The condition generally occurs in nervous patients who are not well nourished and who have enteroptosis. The condition is not necessarily a fatal one, though it has not been recognized. A jejunostomy is the operation to get below the obstruction. Diagnosis is made rather on the continuous vomiting. In some of the cases the obstruction has been near the pylorus, in others below the papilla of Vater, for the patient vomits great amounts of dark, bile-stained fluid. This condition, with both the anti-operative and postoperative types, is a definite entity. No other observer has noted the circular, muscular bands around the duodenum, which Ochsner noted, and who draws an analogy between the pylorospasm and a spasm at the ileocecal valve. Gastroenterostomy has been done several times and found wanting. In postoperative cases the postural method or jejunostomy, might be tried.

DISCUSSION.

Dr. Hemmeter said that an "hour-glass stomach" had been brought to him which, on examination, showed no scar, and proved to be stomach and duodenum. There are three causes for dilatation in hollow muscular organs: First, abdominal fermentation; second, mechanical causes, such as the ring described by Ochsner, and the dragging of the mesentery; third, faults of innervation, Meltzer's reciprocal innervation theory, i. e., simultaneously as an impulse travels through and contracts the longitudinal fibers, the circular fibers relax, e. g., contraction of stomach and loosening of the pylorus. Boas has described infra-papilla and supra-papillar obstructions. In only the cases below the papilla of Vater is their pancreatic juice in the vomitus, hence the trypsin test may be of considerable diagnostic value.

Dr. Cushing agreed with Dr. Hemmeter that the trouble is in the thin-walled stomach and duodenum associated with Glenard's syndrome, and that the tenth nerve is a considerable factor. A division of the tenth nerve in an animal leads to incessant vomiting until death occurs. In the separation of adhesions around a pylorus and gall bladder, the fibers of the tenth nerve may be so injured as to throw out this area and allow dilatation. A case from private practice was a female

57 years old. There was nothing in the past history that had any bearing on the symptoms, except that at 17 years she had had jaundice. She was a thin multipara, with the lower border of the stomach below the umbilicus. At operation a dilated stomach and duodenum were found with the scar of an old ulcer at the pylorus. A pyloroplasty could not be done on account of the sagging of the stomach, so he reversed the pyloroplasty, shortening the lesser curvature. Patient vomited for ten days incessantly, but gradually stopped and now is well. An operation of the same type as this modified pyloroplasty can be done at the ileocecum.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Local Treatment of Erysipelas.

The following combination is recommended by the *Medical Review of Reviews* as a local application in the treatment of erysipelas:

℞. Guaiacol
Tinct. iodii
Spiritus rectificat.
Essentiæ menth. pip., āā..............ʒii 8|

M. Sig.: Apply locally on gauze from two to four times a day.

Gallstones.

A. Hechet, in an abstract in the *Monthly Cyclopedia of Medicine*, recommends in the treatment of gallstones, inasmuch as the preparations of nux vomica increase peristaltic action, and calomel increases the secretory flow, that this combination should serve a good purpose in the prevention of their formation. By this means sufficient peristalsis and biliary flow render it almost impossible for the stasis of bile, without which gallstone formation is improbable. The action of nux vomica also aids the prevention of gallstones by increasing the appetite, and thus exciting the formation of a large amount of bile. The mode of living must necessarily be regulated as well as the diet, in order to prevent infection of the bile tract. In the interval between the attacks of colic, the following combination is recommended by the author:

℞. Hydrargyri chloridi mitis |
Extracti nucis vomicæ, āā.......gr. vi-viiss |40-.50
Extracti rhei........................gr. xx 1|30

M. Ft. capsule No. xxx. Sig.: Two to three capsules to be given daily.

This combination does not produce diarrhea or intestinal colic, and at the same time tends to increase the flow of bile. Gallstone colic requires the administration of morphin hypodermically, with a pill combined as follows:

℞. Podophyllin ....gr. iii |20
Hydrargyri chloridi mitis,.......... gr. vi |40
Ext. nucis vomicæ |
Ext. belladonnæ, āā..................gr. iiss |27

M. Ft. capsulæ No. xx. Sig.: One capsule every two hours until the patient is relieved, then one or two capsules a day.

Treatment of Uremic Convulsions.

W. J. Wilson, in the *Therapeutic Gazette*, recommends in the treatment of uremic convulsions, which is the most dreaded complication in acute or chronic nephritis, and as a complication of pregnancy, that chloroform be first administered to control the convulsions. A thorough movement of the bowels should be secured by the administration of croton oil in 1 to 5 minim doses (.30), mixed with a little sweet oil and dropped on the tongue. As soon as it is possible to do so, the following combination should be administered:

℞. Chloralis hydratis...............gr. x-xxx |65-2.00
Sodii bromidi......................gr. xxx 2|

M. Ft. pulvis. Sig.: To be administered in water by the mouth or by rectal injection.

He also recommends the employment of the tincture of veratrum viride in 4 minim (.25) doses every one or two hours until the pulse is reduced to normal or slightly below normal.

If the patient is plethoric, he recommends the withdrawal of from 12 to 30 ounces of blood by venesection.

In anemic patients, when such measures are employed, the amount of blood removed should be replaced by normal saline solution.

The patient should be placed in a hot pack or a dry hot air or vapor bath. The use of pilocarpin is not recommended by the author as being of such value as was formerly supposed. This outline of treatment is applicable in uremia following either kidney trouble or pregnancy. In cases of pregnancy, unless labor does not set in spontaneously, and the convulsions are not relieved by this treatment, either vaginal Cesarean section or other methods of emptying the uterus must be employed.

Fissure Ani.

The following combination is recommended by *Bulletin Gen. de Therapeutics* as an ointment in the treatment of fissure of the anus:

℞. Cocainæ hydrochloratis |
Ext. belladonnæ, āā.....................gr. i |6
Ichthyoli ....ʒiss 6|

M. Ft. unguentum. Sig.: Thoroughly cleanse the parts and apply locally two or three times daily.

The Treatment of Burns.

After giving the ordinary classification of burns Ambrose McCoy, in *International Journal of Surgery*, states that the first thing to be done is to relieve the pain, and that this should be done promptly.

The important thing in the consideration of the local treatment is to completely exclude the air from the burned surfaces, if possible. The old combination of linseed oil and lime water may be used, but it is not used so much at present as formerly was the case. However, it relieves pain rather promptly and effectively. The disadvantage of this liniment is the difficulty of removing it when once applied and allowed to dry. Another objection the author brings out is that there is a tendency to suppuration after its use. Picric acid may be used in burns of the first and second degree by applying gauze wet with a saturated (5 per cent.) solution of this acid directly to the surface, and over this gauze a layer of absorbent cotton, over which a roller bandage should be firmly applied. The advantage of this application is that it relieves pain, it is a decided antiseptic, and it is not followed by suppuration. It is very easy to remove, as a rule, and the yellow stains which may follow the application of this acid can be easily removed by the application of alcohol. The best dressing, however, according to McCoy, is a combination of carbolic acid and glycerin in varying proportions; one part of carbolic acid to three, four or five parts of glycerin is the strength he recommends. Strips of gauze may be saturated in this mixture and applied to the raw surface. Over this the cotton and roller bandage may be placed, as previously mentioned. He mentions the local anesthetic effect, and the consequent relief of pain on the application of this mixture. It is also a very decided antiseptic. [When carbolic acid dressings are employed the kidneys should be carefully watched.] This treatment may be followed up for the first few days of the injury. If there is a tendency to suppuration after the acute symptoms have subsided, the ulcerating wound is treated in a general way. To aid in the formation of granulation tissue and in the healing process he recommends in this stage the use of ointments, such as carbolic salve, ointments of iodoform or oxid of zinc.

The danger of deformities in severe burns about the hand and wrist is mentioned, and the use of flat splints in such cases is advised. The same precautions should be taken in burns about the knee and elbow joints. In cases of long duration and slow healing, where the burns have extended over a large area, skin grafting may have to be employed. Contrary to the advice of most authorities that dressings should not be changed often, the writer recommends that in cases of burns he has made it a rule to dress the lesions as often or even oftener than in disturbances to the skin produced in other ways. This is owing to the fact that there is a free discharge of serum, and in some cases a free discharge of pus, both of which will require frequent dressing. He, therefore, recommends redressing once or twice daily.

As internal treatment he recommends the maintenance of the free action of the kidneys by the administration of large amounts of water and other liquids.

Medicolegal

Validity of Law Forbidding Marriage of Epileptics.

In 1895 a statute was enacted in Connecticut of which the first section reads as follows: "No man or woman, either of whom is epileptic, imbecile, or feeble-minded, shall intermarry, or live together as husband and wife, when the woman is under 45 years of age. Any person violating or attempting to violate any of the provisions of this section shall be imprisoned in the state prison not less than three years." Was this statute a valid act of legislation? The Supreme Court of Errors of Connecticut considers this question, in the case of Gould vs. Gould, with reference to epileptics only, explaining that the provisions of the act are separable with respect to the different classes of persons with whom it deals, and, so far as this case was concerned, it was enough if it could be supported as to marriages contracted after its enactment by those in the condition of the defendant. It says that the constitution of the state guarantees to its people equality under the law in the rights to "life, liberty, and the pursuit of happiness." One of these is the right to contract marriage, but it is a right that can only be exercised under such reasonable conditions as the Legislature may see fit to impose. It is not possessed by those below a certain age. It is denied to those who stand within certain degrees of kinship. The mode of celebrating it is prescribed in strict and exclusive terms. The universal prohibition in all civilized countries of marriages between near kindred proceeds, in part, from the established fact that the issue of such marriages are often, though by no means always, of an inferior type of physical or mental development. That epilepsy is a disease of a peculiarly serious and revolting character, tending to weaken mental force, and often descending from parent to child, or entailing on the offspring of the sufferer some other grave form of nervous malady, is a matter of common knowledge, of which courts will take judicial notice. One mode of guarding against the perpetuation of epilepsy obviously is to forbid sexual intercourse with those afflicted by it, and to preclude such opportunities for sexual intercourse as marriage furnishes. To impose such a restriction on the right to contract marriage, if not intrinsically unreasonable, is no invasion of the equality of all men before the law, if it applies equally to all, under the same circumstances, who belong to a certain class of persons, which class can reasonably be regarded as one requiring special legislation either for their protection or for the protection from them of the community at large. It can not be pronounced by the judiciary to be intrinsically unreasonable if it should be regarded as a determination by the General Assembly that a law of this kind is necessary for the preservation of public health, and if there are substantial grounds for believing that such determination is supported by the facts on which it is apparent that it was based. There can be no doubt as to the opinion of the General Assembly, nor as to its resting on substantial foundations. The class of persons to whom the statute applies is not one arbitrarily formed to suit its purpose. It is certain and definite. It is a class capable of endangering the health of families and adding greatly to the sum of human suffering. Between the members of this class there is no discrimination, and the prohibitions of the statute cease to operate when, by the attainment of a certain age by one of those whom it affects, the occasion for the restriction is deemed to become less imperative. While Connecticut was the pioneer in this country with respect to legislation of this character, it no longer stands alone. Michigan, Minnesota, Kansas, and Ohio have, since 1895, acted in the same direction. Laws of this kind may be regarded as an expression of the conviction of modern society that disease is largely preventable by proper precautions, and that it is not unjust in certain cases to require the observation of these, even at the cost of narrowing what in former days was regarded as the proper domain of individual right. It follows that the statute in question was not invalid, as respects marriages contracted by epileptics, after it took effect. Furthermore, the court holds that the Superior Court has the power to pass a decree of divorce from the bonds of matrimony in favor of a party to a marriage, not an epileptic, who has been tricked into it by the other party, who was an epileptic, through his fraud in inducing a belief that he was legally and physically competent to enter into the marital relation and fulfill all its duties, when he knew that he was not. The fraud which makes the contract of marriage fraudulent, as that word is used in the statute of divorce, is a fraud in law and on the law. Such a fraud is accomplished whenever a person enters into that contract knowing that he is incapable of sexual intercourse, and yet, in order to induce the marriage, designedly and deceitfully concealing that fact from the other party, who is ignorant of it, and has no reason to suppose it to exist. Whether such incapacity proceeds from a physical or a merely legal cause is immaterial.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

December 16.

1 Cause, Course, Prevention and Treatment of Beriberi. H. Wright.
2 *Short Narcosis, the Short Incision and the Short Stay in Bed After Ideal Operations. B. Holmes, Chicago.
3 Intracorpuscular Conjugation in the Malarial Plasmodia and Its Significance. C. F. Craig, Manila, P. I.
4 Subjective Ozena. J. Knott, Dublin, Ireland.

6 *Pinworms as a Cause of Appendicitis. D. F. Monash, Chicago.

2. Short Narcosis, Short Incision, and Short Stay in Bed After Ideal Operations.—Holmes believes that too much time is often spent by the patient on his back after operation, and too little by the surgeon at the bedside and in the laboratory before the operation. In order to make the stay of the patient short after surgical intervention, he should be studied in the hospital for days or even weeks before operation is undertaken. Holmes has found that patients can readily be kept anesthetized the necessary twenty minutes or half-hour by the employment of gas with only occasional resort to ether. In a few instances, on account of obesity, chloroform has been used to continue the anesthesia. The short incision is one of the dictates of good surgical judgment, as it inflicts the minimum amount of traumatism and gives adequate access to the field of operation. With the small incision, the complications which the protrusion of abdominal viscera add to the operation are unknown. Operators who have been accustomed to use incisions from 4 to 6 inches long are surprised to find that they are able to accomplish the same results more rapidly, with less traumatism and with fewer postoperative discomforts to the patient with an incision 1½ or 2 inches long. The duration of the operation is curtailed, the intoxication and the discomforts of the anesthetic are lessened, the danger of hernia is minimized, the necessity of a long stay in bed is obviated, and the chances of infection through the introduction of many stitches are diminished.

6. Pinworms as Cause of Appendicitis.—Monash states that pinworms are prone to invade the appendix from their habitat in the cecum. Pocketed in the appendix, they and their ova can not be dislodged, and by reinfecting the intestinal tract which has been thoroughly cleansed for relief of pinworms the disorder is obstinately continued. Accumulating in large numbers, they block the lumen and set up violent spasmodic contractions of the appendix in its efforts to expel the contents, thus coinciding with the clinical picture of appendicular colic. After a portion is expelled relief follows and the colicky attack is not repeated until the appendix is again distended by

large numbers of parasites. Repeated attacks are associated with pathologic changes in the mucosa as shown in cases reported. The sharp fine-pointed tail of the female worm which causes irritation of the colonic and rectal mucosa also produces catarrhal changes in the appendix, thereby paving the way for bacterial invasion of the deeper tissues. Anthelmintic treatment is useless, and in an acute attack even dangerous. Removal of the appendix relieves both affections. Two cases are cited.

7. Inhibitory and Anesthetic Properties of Magnesium Salts.—Meltzer reports the results of a number of experiments conducted by himself and John Auer at the Rockefeller Institute. Of the four main inorganic constituents of the animal body—sodium, potassium, calcium and magnesium—the effects on nerve and muscle of only the first three have been very carefully studied, those of magnesium for some reason having hardly been considered at all. In studying the action of various substances injected into the brain Meltzer found that magnesium produced paralysis rather than convulsions. Pursuing this lead, he found that this element with its salts invariably caused depression or inhibition of nervous and muscular action. In a few seconds after the injection of a small dose of the sulphate or the chlorid of magnesium respiration ceased and the animal would die without the struggle of asphyxia and without any sign of sensation unless artificial respiration was practiced for a long time. When injected rapidly, 0.1 of magnesium sulphate is profoundly toxic, but as much as 1.5 of the salt, if injected slowly in the course of an hour, will occasion no untoward symptoms. Herein is the probable explanation of the fact that the sulphate, when taken in the ordinary way, produces no poisonous symptoms; some absorption doubtless occurs, but it occurs so slowly as to be harmless. In another series of experiments it was ascertained that solutions of magnesium salts applied directly to a nerve trunk caused a complete block, abolishing conduction entirely. In a third series it was found that by means of subcutaneous injection of magnesium salts complete general anesthesia, with perfect relaxation of the muscles, but without impairment of the vital reflexes, was produced. In a fourth series of experiments the magnesium salts were injected into the subarachnoid space of the spinal cord, mostly by lumbar puncture. Monkeys were the animals experimented on. The injection of magnesium sulphate in a dose of about 0.06 per kilo of the animal's weight within a minute or two caused complete anesthesia and paralysis of the tail and hind legs. This discovery has been put to practical use in 12 operations performed under the influence of intraspinal injection of magnesium sulphate. The highest dose employed was 0.2 per kilo, or 15 drops of a 25 per cent. solution for each 20 pounds of body weight. In the first 8 cases some chloroform was used to supplement the effect, as the tentative doses of the salt were very small, but in the last 4 the magnesium alone sufficed. The best time for operating was found to be three or four hours after the spinal injection. As a precautionary measure the author insists that the Fell-O'Dwyer apparatus for artificial respiration be on hand whenever this magnesium anesthesia is employed. Finally Meltzer reports the cure of a case of tetanus at Roosevelt Hospital. After the employment of 115 c.c. of tetanus antitoxin without effect, the first injection of a solution of magnesium sulphate afforded great relief for thirty-six hours, and after a few more injections the patient was pronounced cured.

9. Treatment of Communicable Pulmonary Diseases.—Billings describes the routine procedure followed at the tuberculosis clinic of the New York City Department of Health.

13. Treatment of Chronic Constipation.—Macmillan has found the use of rectal tampons a very valuable method of treatment in chronic constipation, of the atonic variety. The tampon is made of absorbent cotton, cheese cloth, or lamb's wool, and should be sufficiently large to cause some distension of the bowel. It can be inserted through an ordinary proctoscope and packed into place by means of a long forceps. The best results are obtained when it is placed at the rectosigmoidal junction. The tampon is provided with a piece of string to facilitate withdrawal at the end of from two to six hours. At first the tampon is used every other day, and the interval between treatments is gradually lengthened as improvement follows.

19 *Dissemination of Tuberculosis as Affected by Railway Travel. C. B. Dudley, Altoona, Pa.
20 General Consideration of the Contagious Diseases of the Scalp and Skin Observed in Children of the Public Schools. J. Sobel, New York.
21 *New Supporter and Pouch for the After-Treatment of Artificial Anus. J. H. Gleason, Manchester, N. H.
22 Centrifugal Urinary Analysis. A. L. Benedict, Buffalo, N. Y.
23 Use of Egg Albumin in the Technic of Staining the Capsules of Bacteria. A. A. Epstein, New York.

16. New Operative Procedure in Intestinal Anastomosis.—The cut ends of the intestine being in position for suturing, Wright introduces three temporary or stay sutures, which divide the circumference of the intestine into three parts. The first suture (they are all Lembert sutures) is introduced at the mesenteric attachment; the second, a third of the circumference of the bowel distant from the first; the third, similarly introduced, two-thirds the circumference of the bowel distant from the first suture. These sutures are left long, their free ends being tied together or secured by forceps. An assistant grasps the first and second sutures, one in each hand, and by firmly drawing these in opposite directions, the free edges of the gut are inverted and come into close approximation, forming a ridge raised above the general surface of the bowel, through which the permanent suture can readily be passed. The operator, with a straight needle threaded with the suture material he prefers, passes the needle through this ridge from side to side, and by continuous suturing the first third of the gut is closed by a continuous modified Lembert suture. The same procedure is carried on in the remaining two-thirds of the bowel circumference. The temporary stay sutures are then removed, or they may be tied and cut. The operation is completed by suturing the mesentery.

18. Amebic Infection of Intacted Urinary Bladder.—It appears that the bladder of Musgrave's patient was infected by a ward attendant who irrigated the bladder without having cleansed his hands after having given colonic irrigations to patients with amebic dysentery.

19. Dissemination of Tuberculosis by Railway Travel.—Dudley believes that experiments carried on by him indicate very clearly that the danger of infection from the upholstery in Pullman cars and coaches is very much less than from naked surfaces, and that the crusade against hangings and carpets and plush is not founded on careful experimental data.

21. Pouch for Artificial Anus.—Gleason has devised a supporter and pouch to be worn by patients on whom a temporary or a permanent artificial anus has been made. The pouch is made of thick, pliable rubber, with an opening 2¼ inches in diameter. Surrounding the opening is a hard rubber (vulcanized) ring ¾ inch in width and having a slightly convexed articulating surface. Attached to this ring are two circular fixing and retaining body straps and two perineal straps. The length from the lower rim of the ring to the convexity of the pouch is 4 inches, the total length of rim and pouch being 7¾ inches.

24 *The Physician's Duty Toward Tuberculosis. A. T. Cabot, Boston.
25 *Four Unusual Cases of Aneurism. E. A. Locke, L. I. H.
26 Some Reminiscences of the Harvard Medical School of Forty Years Ago. D. Coggin, Salem, Mass.

24. **Physician's Duty Toward Tuberculosis.**—Cabot urges the registration of all cases of tuberculosis; disinfection of the premises; instruction and sanitary inspection in case of patients who can not be separated from their homes; sanatoria for curable cases; hospitals for the isolation and care of the actively infectious and seemingly incurable cases; exclusion from schools of children with contagious forms of tuberculosis, and the isolation of tuberculous individuals in prisons and state reformatories.

25. **Unusual Cases of Aneurism.**—The first patient mentioned by Locke gave a history of having had syphilis in youth, tuberculosis of both hip joints of twenty-five years' duration; double inguinal hernia; marked arteriosclerosis; relative mitral insufficiency; tabes dorsalis; chronic interstitial nephritis; deformity of spine; aneurism of the left axillary artery, possibly following trauma, which reached an enormous size and finally ulcerated externally, with the death of the patient five days later. The second patient, also a victim of arteriosclerosis, had an aneurism of the transverse aorta, the first sign of which was a sudden attack of hematemesis. Nine days later he had a second attack which proved fatal after ten hours, from ulceration and hemorrhage into the esophagus at the level of the bifurcation of the trachea. The third patient, a syphilitic, had multiple saccular aneurisms of the aorta which ruptured into the retroperitoneal tissue with subsequent erosion of the vertebræ, hydrothorax and atrophy of the left kidney. The patient died four months after the onset of the symptoms. A fourth patient had multiple aneurisms of the abdominal aorta with ulceration into the third portion of the duodenum and hemorrhage into the stomach and intestines. Death occurred four days after the rupture.

3. **Human and Bovine Tuberculosis.**—Kossel discusses this question in detail and summarizes his paper as follows:

1. By bacteriologic investigation of tuberculous lesions in human beings, cattle and swine, two types of tubercle bacilli can be detected which may provisionally be called *typus humanus* and *typus bovinus*. 2. The widespread tuberculosis of cattle is to be traced exclusively to infection with tubercle bacilli of the *typus bovinus*. 3. Swine are susceptible in a high degree to the tubercle bacilli of the *typus bovinus*, in a lesser degree to those of the *typus humanus*. 4. The tuberculosis of human beings chiefly arises from infection with tubercle bacilli of the *typus humanus*, which is transmissible from man to man. 5. Tuberculous lesions in human beings can be produced by tubercle bacilli of the *typus bovinus*. 6. Tubercle bacilli of the *typus bovinus* can be transmitted to human beings by food derived from tuberculous animals, especially by milk of cows affected with tuberculosis of the udder. 7. The part played by infection from bovine sources in spreading tuberculosis in man is small in comparison to the danger threatening from a consumptive human being.

10. **Treatment of Tuberculosis by Tuberculin.**—Bulloch cites the results obtained in the treatment of 11 patients, the majority of whom were regarded as incurable. There were 2 cases of genitourinary tuberculosis, 2 of gland tuberculosis and 7 of lupus. All the patients except one improved very much under this treatment, seven of them being apparently cured. The case in which there was no improvement was one of extensive abdominal tuberculosis. In one case of lupus the treatment had to be discontinued because, apparently, the inoculations could not be tolerated.

16 Notes from Angola. F. C. Wellman.
17 *Rational Treatment of Dysentery. V. G. Desai.
18 Smallpox Inoculation in India (continued). G. H. Fink.

17. **Treatment of Dysentery.**—Desai urges the value of intestinal irrigation over internal medication in the treatment of dysentery. He uses a hot boric-acid solution, containing one dram of boric acid with a pinch of sodium carbonate to one ounce of water, massaging the abdomen gently during the irrigation. Internally he uses the bark of *Holarrhœna antidysenterica*, a small bushy plant very common in southern India, whose native name is *pandarakorda*. The bark of the root only is used. It is macerated in sour whey, one wineglassful of the solution being taken four times a day. Desai says that this solution is pleasant to the taste and is carminative and diuretic. This drug is far superior to ipecac and acts well in what he terms the "white" variety of dysentery. It also has marked febrifuge properties and produces diaphoresis. He states that ipecac, of value in the treatment of the "red" variety of dysentery, but that some nervous individuals can not take it. Castor oil, he states, invariably cures mild cases of dysentery, especially in children. It flushes out the intestine and removes irritating matter while it is astringent in its after effects. In plethoric patients he finds the following saline solution useful:

℞. Sodii sulph.
Magnesii sulph., āā........................ʒi 4|
Sodii chlor............................gr. x |12
Aq. chloroformi ....℥i 30|

Desai does not approve of giving bismuth or opium till after the intestinal tract has been cleansed of all irritating substances. As a diet he favors pure milk to which a little salt is added. He does not favor soups or albumin water.

24 *Zur Heilung von Pseudarthrosen. P. Jottkowitz.
25 Kasuistischer Beitrag zur Anencephalie und zur Geburt bei derselben. Durlacher.

20. Spirochetes in Syphilis.—Hoffmann's experience now includes 300 cases of syphilis in which the *Spirochæta pallida* was found. Its discovery in fresh, dubious lesions was always followed by the development of the lesions into the unmistakable syphilitic type. He has never found it in non-syphilitic affections, and doubts the accuracy of the technic in the few instances in which others claim to have found it in non-syphilitic lesions.

21. Experimental Production of Aneurisms.—By injection of blood-pressure-raising drugs, such as extract of the suprarenal glands, Fischer succeeded in causing aneurisms in rabbits, but not in dogs. The process was a primary necrosis of the musculature and elastic elements of the media, never arteriosclerosis. His experiments show that in a given affection the etiology is not the essential factor, but rather the organism itself. It reacts to very different toxins with one and the same clinical affection.

22. Technic for Immediate Enterostomy and Artificial Anus.—Offergeld expatiates on the advantages of safely making an opening into the intestine at once in certain conditions, and describes the technic which he has used repeatedly with very satisfactory results. The loop of intestine is brought out, a strip of gauze is passed under it, and it is sutured to the peritoneum and to the fascia. An opening is made in the loop with a trocar, and a Nélaton catheter with a plug in the handle is introduced into the hole thus made and worked through until its tip is in the loop above. A fold is then taken up in the intestine on each side of the catheter, and the two folds are brought together over the catheter and sutured to roof it in, forming a tunnel 5 or 6 cm. long. The escape of gases and fluid feces through the catheter can be controlled with the plug in the catheter to avoid too abrupt changes in the condition in the viscera. The rapidity with which this enterostomy can be done, and its absolute continence, are great points in its favor. After the tunnel has been made and it is desired to make an artificial anus later, the thermocautery can be applied over the opening into the intestine.

24. Treatment of Pseudoarthrosis.—Experience with 2 patients has convinced Jottkowitz that local injection of tincture of iodin in and around the lesion is the best method of treatment. He injected 2 and 4 c.c. respectively, at a single sitting. The resulting pain was bearable, and the treatment resulted in a complete cure. The patients were a young woman with a fractured ankle and a man of 61 with a fractured leg. Tachard has reported similar success from injections of tincture of iodin in 2 cases, after failure of all other measures to induce firm, bony union.

28. Bivalent Serum in Treatment of Diphtheria.—A diphtheria antitoxin is produced in Italy which, it is said, not only neutralizes the toxins, but has a direct bactericidal action. Costantini reports that his experience with it has been very encouraging. In the mild cases, local applications of the serum proved sufficient without injection of the bivalent antitoxic serum. He continues the injections after all symptoms have subsided, thus hastening the final disappearance of the bacilli from the throat. When mixed with a toluized gelatin, the serum adheres to the walls of the throat and thus seems to exert a more intense local action. Costantini has seen no paralytic complications since he has been using this combination of bivalent and bactericidal serums.

29. Treatment of Croupous Pneumonia.—Gugnoni expatiates on the advantages of giving digitalis in croupous pneumonia. It aids in placing the heart in the best possible condition to cope with the infection, strengthening it to resist the toxins of the pneumonia and to overcome the obstacle of the hepatization of the lungs. He gives an infusion of 2 or 3 gm. of digitalis leaves, with water of ammonia and anise, to be taken in twenty-four hours, regardless of whether the heart seems to need it or not. If the heart action is abnormal and does not respond favorably to the influence of the digitalis, the prognosis is almost inevitably bad, although other symptoms may not indicate this at the time. He has thus treated 21 patients.

32. Abdominal Reflexes in Typhoid.—Ortali's researches on 61 typhoid patients confirm Sicard's statement last year that the abdominal reflexes are abolished during the course of typhoid fever, but reappear promptly in convalescence. The stimulus transmitted to the peripheral terminations of the sympathetic nerve in the abdominal walls exerts an inhibiting influence on the reflex center. This center is probably exhausted by the intense and constant stimulation exerted on it by the inflammatory process in the ileum. When the inflammation subsides, this center soon recuperates.

34. Treatment of Rabies with Radium.—Tizzoni's previous communication on this subject was summarized in these columns on page 228. He announced then that the radium rays have a rapid destructive action on the fixed virus of rabies in the test-tube. After two hours of exposure it loses all its virulence. The radium rays, he claims, also deprive the virus of toxicity even after it has been injected into the animal. The action of the radium, he states, was most pronounced when the virus had been injected into the eye. There were no apparent disturbances in the tissues of the eye nor in the eyesight from the exposure to radium even for a period as long as twelve hours. He asserted, further, that fixed virus submitted to the action of the radium rays becomes transformed into an effectual vaccine. He found that one drop or a fraction of a drop of this vaccine injected into the eye induced stable immunity to virus which killed the controls in twenty days. He now reports researches aiming to apply these data to man. He used 2 cg. of radium bromid, representing 100,000 radioactive units, applying the radium in a fused tube inside a mica-topped box. The box was sewed to a cap fitting over the head and orbit, with a lead saucer as a background for the box. The radium was about .5 cm. from the surface of the cornea under the closed lids. This excluded all emanations from the radium, except on the part exposed. The absence of any by-effects was so striking that he asks whether they may not be due to the emanations alone, which were excluded in his work. Exposures of twelve hours failed to induce lesions of any kind in his comprehensive experience. His tests also demonstrated that the *gamma* rays have but a minimal share in the destructive action on the fixed virus, the principal effect being from the *beta* rays. He found it possible to cure rabbits by these radium exposures when the infection dated from two, three or four days before, and even after the fifth day—that is, when the disease had passed through four-fifths of its entire course. These experiments were with fixed virus, which invariably killed the controls the seventh day after the injection. The more fulminating the disease, the shorter the period, probably, in which the treatment is liable to prove effectual. He tabulates the results of other tests which show that in the rabbits cured when the disease had passed through four-fifths of its course, the fixed virus injected under the dura of the posterior brain had diffused through the other hemisphere, and had also invaded the medulla, the part causing the most serious symptoms in the disease in man. The minimal application that saved the rabbits was eight hours of exposure when the exposures were commenced immediately after the injection. On the other hand, eighteen hours' exposure was the minimum when the interval after the injection had been three days and

a half. The brain of the rabbits treated with the radium rays acquired pronounced radio-activity. Sections of the brains exposed showed that when this radio-activity was manifest the rays had been applied the proper length of time to cure the animal. Exposures of less than these minimal applications failed to induce manifest radio-activity. He states that the dose of the rays necessary to save the animal from the effects of the injection of virulent virus can be determined photographically in the individual case. The dosage of radiation will have to be proportional to the mass of the nerve substance to be acted on and to the length of the exposures and number of radio-active unities in the rays. He calculates, therefore, that, as 100,000 unities are enough to cure a rabbit weighing from 1.2 to 1.5 kilos, with the disease already under way, under the same conditions and for the same length of exposure, a man would require sixty to eighty times as much as the rabbit; that is, from 4,000,000 to 6,000,000 radio-active units.

39. Diagnosis of Tabes.—Fratini tabulates the details of 18 cases of tabes to sustain his assertions that the Argyll-Robertson symptom is not constant nor pathognomonic of tabes. It is most constant in the patients with unmistakable syphilitic antecedents. An acute onset of tabes generally is announced by acute paraplegia, which may subside later, to be substituted by simple ataxia. The initial paraplegia may be simulated by astasia-abasia in patients with a tendency to hysteria. In such there is probably an ascending neuritis. The peripheral sensory neuron is in a state of irritation similar to that induced by intoxication with strychnin. This "strychnism," as he calls it, is responsible for the zones of hyperalgesia, for the exaggeration of the tendon reflexes, and for the tendency to tetaniform and epileptiform contractions from repeated stimulation in the zones of hyperalgesia. These phenomena should not be confounded with the spastic phenomena which are induced by lesions of the central motor tracts. The latter are associated with paresis or paralysis and with Babinski's sign, and are due to the abolition of the inhibiting action of the cortex on the spinal reflexes. The phenomena of "strychnism" are characterized, further, by the fact that they are comparatively transient and are never complicated with permanent paralyses. Knowledge of these symptoms reduces the importance of Westphal's sign. There is no single symptom that can be regarded as constant and pathognomonic of tabes. Even the lightning pains may be substituted by mild paresthesia. Tabes should be regarded as a segmented sensory neuropathy, with symptoms due to lesions of the afferent neurospinal system, associated with the Argyll-Robertson symptom and sometimes with crises.

40. Choice of Antiseptics.—Federici's conclusions are in favor of corrosive sublimate as the most effectual and constant in its action of all the antiseptics in vogue. He uses it in a .5 to 2 per thousand solution. Carbolic acid comes next, but a 3 per cent. solution is required in order to obtain as good results.

41. Operative Treatment of Diffuse Septic Peritonitis.—Montini reviews the history of this subject and reports 9 cases in which he has operated. Five of his patients recovered, and he is convinced that others might possibly have been saved if the operation had been undertaken earlier. He affirms that a well-performed laparotomy does not in itself aggravate the prognosis.

42. Pentosuria.—Of the 16 cases of pentosuria which af Klercker has collected, only 4 were in women. The ages of the patients ranged from 18 to 65. The 2 cases he has personally encountered were in Jews, brothers. The father and another brother were diabetics. A family tendency is also evident in the total 16 cases, as 7 of the patients were related in three families. The frequent coincidence of neurasthenic symptoms deserves attention. The prognosis probably is not so grave as in case of diabetes. No specific treatment for pentosuria has yet been found. Transitional conditions between pentosuria and diabetes are known, and the slight pentosuria sometimes noted in diabetes should be studied further, although it should not be classed with genuine pentosuria. It is possible that a family tendency to diabetes may be a factor in the origin of this condition. The proportion of pentose in the urine diminishes with insufficient food, although af Klercker does not think it probable that the mother substance of the pentose in the urine is derived from the carbohydrates. Neuberg's hypothesis in regard to galactose and his conception of the pentose in the urine as "r—arabinose" deserve further study. A bibliography of 130 articles is appended, giving the titles in full. The article is in German. In conclusion, af Klercker states that when the urine, even after fermentation, reduces Fehling's solution pentosuria should be suspected. He describes a simple test for it.

43. Chronic Nephritis with Special Regard to Nitrogen Metabolism.—Ernberg's article is based on considerable clinical experience, as well as on extensive experiments on healthy persons. His study of the time of elimination of nitrogen, after a test meal containing large proportions of albumin, showed that the normal curve of elimination is an easily determined standard from which pathologic conditions show characteristic variations. He thinks that this may prove to be an important and valuable aid in the diagnosis of nephritis and of its different forms. His research further shows that a diet with much diminished albumin content, and hence minimal albumin metabolism, is of advantage under certain circumstances. A diet leading rapidly to the minimal transformations of nitrogen seems rational in case of nephritis and worth trying. His "albumin test breakfast" was 150 gm. beef (weighed raw), 50 gm. bread, 20 gm. butter and 250 c.c. milk. The urine was collected every two hours during the following eight hours. On a "nitrogen-starvation diet" less urine-making substances are generated than on any other diet yet tried in nephritis. It lightens the work of the kidneys and relieves them to an astonishing extent as the albumin metabolism becomes reduced. If the albuminuria can be regarded in certain cases as an index of the irritable condition of the kidney, then these researches establish that diminishing the albumin transformations reduces at the same time the irritability of the kidneys. There is less thirst on the "nitrogen-starvation diet," which is an advantage in certain cases. The researches reported indicate further that the elimination of residual nitrogen in the kidneys and in the blood is materially promoted by the reduction in the albumin metabolism. This suggests the possible value of the "nitrogen-starvation diet" in incipient uremic conditions. He defines this diet as one with a minimal amount of nitrogenous substance, although providing amply for energy otherwise, kept up for periods of four or five days or longer, with comparative abundance of albumin in the intervals. Such a diet might comprise bread and cakes, potato purée, spinach, porridge with cream, sugar, butter, cream, cooked fruits and lemons, averaging at least 35 calories per kilo of body weight during the twenty-four hours for a person confined to bed.

49. Retroflexion.—Twenty years ago Vedeler published a review of 3,200 cases of retroflexion. At that time it was considered absolutely abnormal, while now it is considered only relatively so. It may exist without symptoms, although these are liable to develop at any time. He regards fixation of the uterus as contrary to the laws of anatomy and physiology. Pessary treatment conflicts with modern ideas of asepsis and infection. The diseased retroflexed uterus, he thinks, should be treated according to the same principles as the diseased anteflexed organ. He found anteflexion in 64 per cent. of 7,200 women, retroversion in 20 per cent., retroflexion in 9 per cent., and anteversion in 7 per cent. He observed in 62 cases the spontaneous transformation of retroflexion into anteflexion, without morbid changes in the uterus.

GENERAL INDEX.

All reading matter in The Journal from June to December, inclusive, 1905, is indexed here. (For Current Medical Literature Index see pages 2057 to 2083.) All societies, congresses, etc., are grouped under the general subject of "Societies" at the end of the letter "S." Similarly, all "Deaths" and all "Book Notices" are indexed under those titles at the ends of the letters "D" and "B", respectively. Matter pertaining to the Association is under "Association News." With the above exceptions, all matter is indexed under the most important word of the heading that was used in The Journal. It is, therefore, well to remember that in looking up a certain subject, related words should be consulted, for example, bone, ostitis, periostitis, inflammation, etc. The letters used to explain in which department the matter indexed appeared are as follows: "E", editorial; "O", original article; "T", therapeutics; "P", pharmacology; "Ml", medicolegal; and "ab" denotes an abstract of an article that has appeared in full elsewhere.

Sponges, a method of sterilizing, 1525—ab
Sputum, case of systemic blastomycosis with blastomycetes in, 1045—O
Squint, 66—ab
  present treatment of, 1271—ab
Stammerers, institutions for, 1266
Staphylococci, latent, in the blood, 664—ab
State Department of Health, some provisions for, 1358-Mi
  medical journals, new, 248—E
Statements, alleged unscientific, by physicians, 478
Status epilepticus, treatment of, 71—ab, 419—T
  lymphaticus and the ductless glands, 346—ab
  social, of tuberculous persons, 872—ab
Steeves, A. M., physician's duty to the child, from a dental standpoint, 514—O
Stengel, A., chronic acetanilid poisoning, 243—O
Stenosis, of intestine, after reposition of incarcerated hernia, 1285—ab
  pyloric, in an infant, 1606—ab
Sterilization, artificial, 225—ab
Stern, H., chairman's address before section on pharmacology at fifty-sixth annual session of American Medical Association, 1535—O
Sternum, to outline bodies behind the, 1527—ab
Stevens, B. F., case of accidental eserin (physostigmin) poisoning with recovery, 1655—O
Stevenson, M. D., description of an advancement suture, 764—O
Stewart, J. C., anaerobic cellulitis, 528—O
Stinson, J. C., improved operation for hypospadias involving glans and penile portion of urethra, 1726—O
Stitch, twine triangular, for gastroenterostomy and entero-enterostomy, 426—ab
Stockton, C. G., delay of old age and alleviation of senility, 165—O
Stockton, C. G., food stagnation from all causes, 1389—O
Stokes-Adams syndrome, 873—ab
Stomach, acute dilatation of, 1767—ab
  adenocarcinoma of, 2028—ab
  and intestines, skiagraphy of, 1523—ab
  and intestines, study of, 1353—ab
  brief consideration of surgical treatment of diseases of, 1360—ab
  carcinoma of, 220—ab
  chemical tests, of functions of, 664—ab, 1123—ab
  chronic ulcer of, and first portion of duodenum, 1211—O
  congenital small, 816—ab
  contents, expulsion method of obtaining, for diagnostic purposes, 1445—ab
  diagnosis of cancer and ulcer of, 1360—ab, 1444—ab
  digestion leucocytosis and cancer of, 1088—E
  dilatation of, from atony, 226—ab
  disorders, relation of, to diabetes mellitus, 1823—ab
  endothelioma of, 364—ab, 1530—ab
  experimental study of accuracy of modern clinical methods for diagnosis of disorders of, 70—ab
  gunshot wound of, 106—O, 133—ab
  hourglass, 1036—ab
  new technic for determination of secreting and evacuating functions of, 810—ab
  non-malignant disease of, 1364—ab
  operative treatment of callous ulcer of, 293—ab
  pathology and non-surgical treatment of injuries of, 67—ab
  present status of surgery of, 1353—ab
  remarkable collection of foreign bodies removed from, 1032—ab
  removal of, 1526—ab
  resection of, in 101 cases of cancer, 1529—ab
  Roentgen examination of, 881—ab
  secretions, in gynecologic affections, 1123—ab
  surgical treatment of bleeding ulcer of, 1693—ab
  surgery of the, 1693—ab
  treatment of hyperacidity and hypersecretion of, 661—ab
  tube, combined mouth gag and protector, 1573—O
  tube, use and abuse of, 737—ab
  ulcer and cancer of, 873—ab
Stomatology, indications for scientific progress in, 369—O
Stone, I. S., Columbia tissue and intestinal forceps, 403—O
Story, a Christmas, 1955—O
Stovaine as a local anesthetic, 1207—ab, 1201—ab
Strabismus, lateral displacement of tendon insertions for cure of, 522—O
  two cases of functional, 873—ab
Street noises, evil of, town clock nuisance abolished in Birmingham, 1668
Streptothricosis, pulmonary, 784—O
Stricture, congenital urethral, associated with hematuria and symptoms of renal disease, 495—ab
Strictures, ulcers above, 528—ab
Student life, 1199—ab
Students, instruction of, in examination for insurance, 417—ab
Subcutaneous operations, correction of nasal deformities of, 218—ab
Sublimate, toxic action of, 295—ab
Submucous resection operation for deviation of nasal septum; with distribution of several new instruments, 1824—ab
Subtle poisons, 1813—P
Sugar, as food for diabetics, 431—ab
  catalytic influencing of oxidation of, 1453—ab
  Pavy's quantitative test for, 1369—ab
  rapid estimation of amount of, in urine, 660—ab
  utilization of, enemata in diabetes, 1913—ab
  statistics, 469—E
Suicide and self-manslaughter, 1959—E
  prevention, 1740—E
Sulphur, treatment of chronic nasal catarrhs with, 656—ab, 1756
Sunstroke, an unusual case of, 1167—O
Superstitions, some gynecologic, 872—ab
Suprarenal extract in asthma, 1756
  functioning, study of, in disease, 362—ab
Surface waters and sewage, longevity of bacillus typhosus in, 1269—ab
Surgeon and pathologist, 149—ab
Surgery, actual results of cerebral, at Massachusetts general hospital, 423—ab
  address in, 66—ab
  artificial hyperemia in, 1270-ab
  commerce of, 186—O
  contribution to study of spinal, 494—ab
  French congress of, 1667
  requirements and qualifications for successful career in, 2027—ab
  responsibilities of, 1039—O
  results in non-traumatic, of brain at Boston City Hospital, 423—ab
Surgical dressing, 1270—ab
  practice on lower animals, 407—E
  technic, simple aseptic, 349—ab
Suture, description of an advancement, 764—O
  new materials for, 1431—ab
Suturing, aid to rapid, 429—ab
Swaim's ointment and panacea, 416
Sweating, paradoxical, in a child, 817—ab
Swisher, T. J., carbolic acid burn, 717—O
Sycosis, lupoid, clinical lecture, 849—O
Symblepharon, operation for, 1994—ab
Symbiosis, fuso-spirillar, 718—E
Symphyseotomy, extramedian, 77—ab
  extramedian, or pubiotomy,1911—ab
Symptoms, passing of pathognomonic, 467—E
Syncytioma malignum, 1705—O
Syphilids, serotherapy of, on new basis, 227—ab
Syphilis, 1273—T
  and tabes, 226—ab
  and repair fractures, 1974
  case of peripheral nerve, 177-O
  cerebral hereditary, 1984—ab
  congenital, and the spirochæte pallida, 77—ab
  consideration of late hereditary, 1276—ab
  convenient points for intramuscular injections in treatment of, 873—ab
  elements of diagnosis of cutaneous, 95—O
  etiology of, 108—E, 953—ab, 1985—ab
  exanthemata, clinical lecture, 849—O
  extragenital, 1994—ab
  hypodermic use of salicylate of mercury in, 493—ab
  inherited to third generation, 428—ab, 948—ab
  mammary, with involvment of glands, simulating cancer of breast, 1521—ab
  maternal, 1065—O
  method of administering mercury in, 1603—ab
  Schüller's parasites in inherited, 141—ab
  spirochetes in, 137—ab, 421—ab, 663—ab, 808—ab, 953—ab, 1126—ab, 1182—ab, 1209 ab, 1276—ab, 1307—ab, 1366 ab, 137—ab, 1497—O, 1527 ab, 1698—ab

Syphilis, treatment of, by intramuscular injection of mercury, 1829—ab
  unusual case of laryngeal, requiring tracheotomy, 1523-ab
  urine in secondary, and under mercurial treatment, 141—ab
Syringe versus irrigator in gonorrhea, 875—ab
Syringomyelia, 63—ab
  unilateral, in a child, 1280-ab
Systole, extra, 666—ab

CURRENT MEDICAL LITERATURE

INDEX OF TITLES

Explanation: The reading matter which appeared in THE JOURNAL is not indexed here, except the original articles and the abstracts of original articles. This index includes the titles and the subjects of original articles published in the leading medical journals of the world during the past six months. The titles and the names of the journals in which they appeared were published weekly in the Current Medical Literature Department, to which references are made. The figures in parentheses refer to the paragraph; the number following, to the page in THE JOURNAL. For instance, "Abdominal Symptoms, acute, (1) 222—ab" refers to page 222 of THE JOURNAL, on which is found opposite paragraph 1 the title of the paper and the name of the author, viz.: "Acute abdominal symptoms. W. W. Cheyne." This title is listed under the journal in which the article appeared, *British Medical Journal*, June 17. The "ab" indicates that an abstract of the article appeared in THE JOURNAL, which will be found below the title on page 222. Titles of articles which appeared in THE JOURNAL are indicated in the index below by an asterisk (*) before the page number. Index to authors of all the articles below is on pages 2085 to 2096 of this index.

A

Abdomen, closure of, by longitudinal suture, (92) 358
  conservative surgery of, (118) 1031
  importance of making thorough examination of, in all acute bowel diseases, (77) 1762
  methods of exploring, and a new one, (26) 1606—ab
  pathology of suppurative processes in, (91) 1609
  penetrating and perforating gunshot and stab wounds of, (33) 1446—ab, (3) 1758—ab
  practical significance of certain common symptoms in upper, *98
  remarkable case of wound of, with prolapse of large intestine, (7) 1204
  subparietal injuries of, (45) 495—ab
  two cases of penetrating gunshot wounds of, and one of gallstone disease, (114) 813
  what suburban surgeon is doing in, and how he does it, (30) 809
Abdominal and pelvic diseases, renal affections simulating, (124) 1280
  and pelvic operations, phlebitis following, *1792
  cases, interesting, (80) 881
  cavity, diagnosis of suppurative processes in, (92) 1609
  cavity, forms and etiology of suppurative process in, (90) 1609
  cavity, plea for surgical intervention in suspected malignant disease of, (160) 498, (19) 737
  cavity, treatment of suppurative processes in, (93) 1609
  conditions, difficulties in diagnosis of, (56) 1447—ab
  diagnosis, (91) 221
  diagnosis, cases illustrating some difficulties in, (1) 942—*ab*
  injuries, treatment of, with special reference to gunshot wounds, (73) 356
  operations, transverse incision in, (17) 1690
  section, conservation of parietal motor nerves in, (64) 1203
  section, immediate mortality in, (38) 1118—ab
  section, technic of, (21)1200-ab
  surgery during last twenty-five years, (1) 877
  surgery, notes based on completed records of 744 cases, (13) 877
  symptoms, acute, (1) 222—ab
  troubles, errors in diagnosis of, (48) 657—ab
  wall, fibroid growths of, *676
  wall, large desmoid tumor of, (1) 1198—ab
  wall, overlapping aponeuroses in closure of wounds of, (85) 1279—ab
  walls, disinfection of, (29) 499—ab
  walls, reflexes of, (123) 745
Abnormalities, circulatory and anatomic, of an acardiac fetus of rare form, (13) 1365
Abortion, (67) 425, (74) 1363
  general considerations on criminal, (73) 947
  management of, (27) 2032
Abortions, (33) 657
  permissibility of medical, (97) 1280—ab
  suggestion in surgery of, (59) 1119—ab
Abscess, aborting of liver, plea for early punctures, (21) 743
  appendiceal, pathology and treatment, (75) 1609
  brain, two fatal cases, (48) 875
  central, of otitic origin, (38½) 1446
  cerebellar, due to infection through internal auditory meatus, (8) 2032
  epidural, (100) 358
  in frontal lobe, (141) 746
  obscure case of alveolar, (13) 1120
  observations on cause and treatment of perineal, and of periurethral suppurations above triangular ligament, (7) 1520—ab
  operation for cerebral, (34) 423
  otitic brain, in left temporal lobe with peculiar form of speech disturbance, (79)1833
  perinephritic, (79) 947
  perinephritic, recurrent, of twenty-six years' standing, (51) 134
  perirectal, (53) 73
  psoas, unavoidable errors in diagnosis of, (1) 288—ab
  seven cases of liver, (27) 1829
  subphrenic, (67) 1766—ab
  subphrenic, operative treatment of, (64) 743—ab
  surgery of otitic brain, (56) 495
Abscesses, perinephritic, in children, (59) 1278, (66) 1828
  post-typhoid, and hypodermic injections, (110) 228—ab
  safe and adequate method for opening retropharyngeal, in children, (63) 495—ab
Acarus in transmission of leprosy, (70) 1992
Accidents, probable explanation of some drowning, (6) 1204
Acetanilid, chronic, poisoning, *243
  poisoning, (88) 1364
Acetone, test for, (42) 1034—ab
Acetonuria in infectious diseases in children, (82) 817
  in non-diabetic surgical cases, (22) 218
Achillotomy and fasciotomy in patient 72 years old, (70) 1608
Acid diethylbarbituric, (73 1119
  intoxication, in chronic gastrointestinal affections in infants, (69) 663
  musculo-tonic and diuretic action of formic and the formates, (44) 1608
  study of therapeutic value of hydrochloric, in diseases of stomach, (25) 1028—ab
Acidosic and sugar states from traumatism, treatment of, (50) 1827
Acidosis in children, (83) 817
Acids and alkalies, balance of, in animal fluids, (73) 1767
Aciduria as cause of deaths following administration of chloroform and ether, (18) 948—ab
Achondroplasia, case of, (17) 428
Acne, (57) 1988
  punch method of treating, (85) 295—ab
  treatment, (24) 291, (11)422—ab
Acrodermatitis chronic atrophicans, (46) 495
Acromegaly, case of, *1403 (116) 1448
  with symptoms of myxedema, (21) 1445
Actinomyces, case of pulmonary infection with an acidfast, (44) 1028
Actinomycosis, (39) 219, (63) 356, (77) 1694
  affections simulating, (48) 293—ab
  limited to urinary tract, (41) 1907—ab
  of lung, (61) 1761, (3) 1762
  treatment of, and blastomycosis with copper salts, *1492
  two cases of, (17) 498
Adams-Stokes syndrome, (36) 657
Addison's-disease, (50) 1608
  and effect of administration of suprarenal extract, (18) 877—ab
  case of, (92) 659, (2) 1694—ab
  therapeutic use of x-rays in, (34½) 661
  without pigmentation, (170)660
Address, annual, before Providence Medical Association, (36) 221
  annual, of president of Denver Academy of Medicine, (62) 1524
  before American Hospital Superintendent's Association, (18) 1691—ab
  chairman's, before section on pharmacology, at fifty-sixth annual session of American Medical Association, *1535
  College of Medicine of University of Southern California, (78) 1828
  college of physicians and surgeons, (109) 427
  commencement exercises of Ohio Medical University, (111) 659
  delivered before graduating class of Pacific Hospital Training School for Nurses, Los Angeles, May 13, 1905, (101) 876
  insane of Canada, presidential, (24) 809
  introductory, to course of study delivered before medical school of McGill University, (24) 1276
  Missouri State Medical Association, (81) 426
  of president of State Medical Society of Wisconsin, (72) 741
  of welcome to Ohio State Medical Association, (115) 876
  on morbid growths, with suggestions as to treatment, (10) 1281
  presidential, delivered before the Lancashire and Cheshire branch, alcohol as a therapeutic agent, (2) 358—ab
  presidential, delivered before Metropolitan Counties branch, (1) 358
  president's, Iowa Medical Society, (90) 876
  president's, American Orthopedic Association, (46) 740
  president's, Mississippi Valley Medical Association, (32) 738—ab
  president's, Ohio State Medical Association, (114) 876
  president's, Oklahoma Medical Society, (158) 660
  president's, Pacific Association of Railway Surgeons, (34) 1446
  president's, Portland City and County Medical Society, (127) 877
  president's, South Carolina Medical Assn., (127) 497
Adenocarcinoma, metastasis of, in mice, (58) 430
Adenoid vegetations as favoring epidemic cerebrospinal meningitis, (62) 431
Adenoids, (20) 656
  cause of children's disease most frequently overlooked, (23) 1521
  effect of presence of, and other abnormalities in nasopharynx on some affections of eyes, (13) 947
  etiology and symptoms, (33) 809
  from standpoint of parent and general practitioner, (42) 1446
  mental and moral effects of removal of, (11) 1758
  nasopharyngeal, (28) 1360
  position of patient in removing, under general anesthesia, (52) 220—ab
Adenoma of meibomian glands, (73) 136
Adenomyoma of corpus uteri, clinical history of, (98) 1286
Adnexa, indications for operative or non-operative treatment of affections of, (33) 1697—ab
  treatment of chronic inflammation of, (91) 1124—ab
Adolescence in girls, (39) 657
Adrenalin, accident with, (71)946
  chlorid, successful use of, in appendicitis, (88) 813
  effect of experimental conditions on vascular lesions produced by, (41) 1692
  experimental investigations of, (35) 743
  untoward effect of, in urethra, *1086
Adulteration and substitution, (23) 71

Adulterations, food and drug, (125) 222
Advantages of simple surgical equipment and technic, (64) 135—ab
Advertising, report of committee to aid postoffice department in excluding objectionable, *843
  sanctimonious, (115) 1447
Affections, treatment of certain, interesting both physician and surgeon, (8) 2031
African horse and cattle disease, results of Koch's research on, (39) 360
After-birth, medicolegal aspect of retained, (57) 879
Aged and infirm, care of, in tropics, (18) 1825
  depression in, (90) 1038—ab
Agents, therapeutic, of animal origin, (104) 1203
Agglutinability, persistence of, in typhoid bacilli in water, (63) 813—ab
Agglutination, studies in, in tuberculosis, (17) 1905—ab
Aggressin coli bacterium, specificity of, (68) 743
  formation, (57) 816
  of tubercle bacillus, (63) 500
Aggressins, (49) 500
Aggressiveness, relations between, and body substance of bacteria, (81) 1912
Ainhum, *87, *631, *2015
Air examinations — importance and results of, (49) 1119
  passages, bacteriology of fibrinous inflammations of, (35) 1034—ab
  passages, visual inspection of, (49) 1528—ab
  use of liquid, in surgery and skin diseases, (28) 878—ab
Albers, spot in pelvis, (56) 1765
Albumin, delicate test for, in urine, (118) 813
  determination of remains of, in food by thiosinamin, (55) 1451—ab
  digestion of, (86) 1529
  in urine of apparently healthy children; renal and cardiovascular changes as seen in Southern California, (85) 357
  modern research on, (54) 1527
  requirements, minimal, in health and disease, *1775
  differentiation of various, from same organism, (87) 226
Albuminuria, (93) 741
  alimentary, (67) 817—ab
  and diabetes, (37) 950—ab
  and eclampsia, treatment of, in pregnancy, (7) 1280
  discrimination of physiologic, from that caused by renal disease, (14) 1610—ab
  essential, (56) 1035—ab
  in pregnancy and premature birth, (60) 879
  in typhoid, (69) 79
  of adolescents, (5) 1448—ab
  pathology of, (43) 1830—ab
  prognosis and treatment of, (82) 141—ab
  senile, (19) 354
Albumosuria, (95) 665—ab
  of phthisis, *1862
Alcohol, action of, on circulation, (53) 431—ab
  and drug habitué, predisposing and acquired characteristics of, (55) 1988
  and strychnin, (39) 1205—ab
  and venom, (39) 1205—ab
  as cause of increase of crime and mental affections, (103) 666
  forms of insanity due to, especially in medicolegal relations, (74) 1031
  inebriety and some medical problems of, (76) 1031
  influence of, on thyroid gland, (46) 1765—ab
  injuries and lesions following toxic use of, (48) 1608
  methyl, amblyopia with special reference to optic nerve, *1560
  mortality, (107) 666
  pathologic effects of, on rabbits, *780
  present position of medical profession in relation to (75) 1031
  tremor as sign of abuse of, (34) 224—ab
Alevolar osteitis, preliminary note on treatment of, by vaccine, (9) 1120
Alexander-Adams operation, (55) 225—ab
Alexander operation through median incision, (43) 944—ab
Alimentary canal, permeability of, for bacteria, (92) 1038—ab
Alkalies and acids, influence of, on stomach secreting function, (62) 879
  influence of, on degree of acidity of urine in anemia, (95) 882—ab
Alkalinity, relation of index of, to production of diphtheria toxin, (131) 1280
Allyl mustard oil, action of, on liver and kidneys, (50) 743
Alopecia areata, clinical lecture, *849
  atropic, (29) 76, (19) 359—ab
Amaurosis from filix mas, (81) 136
Amblyopia, apparently toxic, following influenza, (12) 947
  case simulating toxic, (69) 221
  ex anopsia, proof of existence of, in strabismus, (96) 813, (64) 946
  high frequency current in nontoxic, (24) 1360
  methyl, alcohol, with special reference to optic nerve, *1560
Amblyopias, non-toxic, *611
Ambulance wagon, voluntary civil, (6) 813
Amebiasis, intestinal, (130) 813
  pathology of intestinal, *1371
  symptoms, diagnosis and prognosis of uncomplicated intestinal, in tropics, *830
American disease, an interpretation, (13) 1199
  [illegible] origin, *145
  [illegible] inciples of ethics of, (11) 1984
  medical assurance, *179
  Urological Association, (103) 497
Ammonia, poisoning by fluid, used for domestic purposes, (13) 137
Amnion epithelium, activity of, (104) 1286
Amniotic constriction, injuries from, (59) 952—ab
Amputation, Bier's osteoplastic, (12) 1908
  modified technic of interscapulothoracic, (39) 1282—ab
  survivals after interscapulothoracic, (38) 1282—ab
Amputations, (168) 498
  intrauterine, and amniotic bands, (59) 135
Amyloid degeneration, (43) 743
  preparations, durable specimens (44) 743
Anakhre goundou, (101) 364—ab
Analgesia, regional in surgical treatment of anorectal diseases, (4) 493—ab
  spinal, (61, 64) 1207—ab, (72) 1207, (69) 1524, (59) 1766—ab
Anastomosis, end-to-end, (47) 78—ab
  new operative procedure in intestinal, (16) 2031—ab
  intertesticular, (55) 1831—ab
Anatomic anomalies encountered during mastoid operation, (97) 427
  eponyms, (45) 355, (165) 498, (105) 1120
Anatomy, comparative, of anterior cerebral artery, (32) 134
  conservation or restoration of normal, in gynecologic surgery, *1583
  teaching of, (33) 494
Anchylostomiasis, (77) 79
Anemia, case of infantile splenic, (11) 223
  case of probable pernicious, plus leukemia, (60) 431
  diagnosis and treatment of, (28) 1445, (21) 1521—ab
  four cases of essential, and their diagnostic differentiation, (17) 1605—ab
  infantile, (65) 1524
  miners', in army, (25) 428—ab
  nervous and mental manifestations of pre-pernicious, *1635
  pernicious progressive, caused by micrococcus tetragenus, (108) 1125
  pernicious, with improvement after administration of liquor potassi arsenitis, (97) 659
  progressive pernicious, (33) 77—ab
  relative valvular defects in, (101) 1769—ab
Anemia, splenic, with hemoglobinemia, and decreasing splenomegaly, (57) 425—ab
  three cases of progressive pernicious, and one of grave symptomatic, (104) 501
  tropical, (3) 69
Anencephaly, (25) 2032
Anesthesia, accidents of, (120) 1031
  acid intoxication and late poisonous effects of, *691, *754
  and operating table, (80) 953
  associated with hyperalgesia of areola-nipple area of both breasts, a new and apparently constant stigma in hysteria, (49) 1827
  chloroform and ether, (31) 355—ab
  clinical effects of ether, on renal activity, (2) 1120—ab
  cocain adrenalin in general surgery, (140) 746
  complete, by the subcutaneous and stomach routes, (30) 949—ab
  defense of general, (87) 362
  ether, (85) 1614—ab
  ethyls in general, (38) 423
  general, notes on, (83) 1694
  improved technic for overpressure, (44) 1611—ab
  in throat surgery, (15) 133-ab
  local, (72) 880, (90) 1209-ab (80) 1912
  local, for suturing wounds, (98) 296—ab
  local versus general, in rectal surgery, (30) 72—ab
  lumbar, with stovaine, (64) 1207—ab
  medullar by cocain—suprarenin, (91) 1769
  nitrous oxid-ether, (132) 358
  plea for, in radical cure of inguinal hernia, (7) 1443—ab
  present status of spinal, (72) 1207
  psychical phases of, (86) 1203
  relations between chloroform, and elimination of ureic nitrogen, (104) 227
  satisfactory, of short duration, (121) 1031
  spinal, (51, 64) 1207—ab, (72) 1207, (69) 1524, (59) 1766—ab, (42) 1910—ab
  under plus atmospheric pressure, (61) 1912—ab
  vapor method of, (8) 1358-ab
Anesthetic, selection and administration of, (121) 742
  use of somnoforme, (61) 135
Anesthetics, effect, on bladder, (32) 139
  experiences with, in 700 cases, (66) 362
  new, (57) 1992
Aneurism, aortic, unusually large, (78) 658, (44) 1361—ab
  bullet wound, (83) 80—ab
  experimental production of, (21) 2033—ab
  four unusual cases of, (25) 2032—ab
  innominate, simultaneous ligature of right carotid and subclavian arteries, (12) 75, (7) 1448
  in tabes, (49) 1362
  innominate, reported in 1898, (33) 291
  Matas operation, for radical cure of, *395, (1) 736—ab
  of abdominal cavity, (13) 1525
  perforating thoracic, pointing externally through the sternum, with non-fatal rupture, (77) 1363
  popliteal, in boy cured by Hunter's operation, (16) 1609
  popliteal, surgical treatment, (25) 254
  recovery after removal of large, in thigh, (24) 1033—ab
  sacculated, of abdominal aorta, (18) 814—ab
  sequel to case of innominate, spurious, (55) 362
  three cases of intradiaphragmatic and one of supradiaphragmatic aortic, (34) 289
  two cases of thoracic and one of innominate aneurism treated by wiring and electrolysis, (57) 657—ab
  treatment of arteriovenous, of the subclavian, (39) 1121-ab
Aneurisms of the groin, (92) 1447
  operative treatment of, (73) 1993—ab
Angina, a bacillus fusiformes, (118) 745
  Ludwig's, (136) 144—ab
  pectoris and allied conditions, (11) 1204—ab
  pectoris, inquiry into cause of, (3) 1448—ab
  Plauti-Vincent's, (77) 1123, (96) 1370
Angioma arteriale racemosum of skull, treatment of, (51) 1992
  discrete, of septum, (10) 1908
  negative results of treatment, with pencil-shaped sticks of magnesium, (68) 1528
Angiomas, primary muscle, (80) 1285
Angiomata, bloodless treatment of, (88) 142—ab
Angiospasm and uremia, peripheral, (102) 227—ab
Angola highlands, tropical diseases of, (22) 656, (27) 737, (17) 809, (27) 873, (16) 2032
  notes from, (28) 1909
Animal food, increase in consumption of, in past fifty years, (4) 427
Ankle, anatomy of, in tuberculosis of, (52) 1765
  joint, patient cured of tuberculous disease of, (128) 877
  sprained, (38) 1986—ab
Ankyloblepharon, (135) 659
Ankylostoma larvæ, passage of, through intact skin, (79) 1036
Ankylostomata, destructive action of salt water on larvæ of, (38) 139—ab
Ankylostomiasis in Japan, (94) 665—ab
  or uncinariasis, *588
Ankylostomum americanum, (89) 1530
Anterior cerebral artery, comparative anatomy of, (32) 134
  poliomyelitis, acute, with special reference to stage of invasion, (56) 1608
Anthracosis, relation between, and pulmonary tuberculosis, (48) 945
Anthrax, case, probably due to inoculation—without a visible initial lesion, (6) 1758
  cutaneous, treated without excision with Sclavo's antianthrax serum, (4) 498
  serum treatment of, (82) 501
Antibodies, production of, a secretory cellular process, (32) 360
  specific, in tapeworm hosts, (84) 1453
Anticomplements, (53) 1527
Antidiphtheric serum, experiments to determine antitoxic depreciation of, (6) 1520—ab
Antihemolysin, (74) 743
  or normal serums, (64) 1699
Antiseptics, choice of, (40) 2034—ab
  internal, (67) 1988
Antitetanic serum in gunshot wounds, (35) 576
  serum, intracerebral injections of, (50) 135—ab
Antitoxin, clinical experience with, and advantages of large doses, (28) 72—ab, (18) 133
  unusual dosage in case of scarlet fever complicated by diphtheria, (5) 1758—ab
  use of, in other diseases than diphtheria, (137) 1364
  use of diphtheria, in cerebrospinal meningitis, (67) 496
Antitoxins, passage of, into milk and their absorptions in the alimentary canal, (94) 1530—ab
Antrim of Highmore, (51) 220
  of Highmore, chronic empyema of, (32) 1522
  of Highmore, operative treatment of empyema of, (76) 496—ab
Anuria, decapsulation of kidney for scarlatinal, (99) 1769—ab
  fatal reflex, after nephrectomy, (69) 1912
Anus, case of imperforate rectum with absence of the, *1305
  malformation of, (68) 425
  new supporter and pouch for after-treatment of artificial, (21) 2031—ab
Aorta, complications of aneurism of, (80) 1994—ab
  general narrowing of, (63) 952—ab

Aorta, importance of manual compression, in postpartum hemorrhages, (112) 666—ab
  ligature of abdominal, (51) 78—ab
  multiple aneurism of, (115) 813
  sacculated aneurism of abdominal (18) 814—ab
Aortic adhesions, (68) 74
  and mitral disease, combined, in rheumatic children, (1) 1448
  insufficiency, with postmortem examinations, (48) 1362
Aphasia, motor, without agraphia, (19) 1449—ab
  optical, (53) 1827
Apoplexy, tardy traumatic, (51) 1450—ab
Apparatus, behavior of circulatory, in acute infectious diseases, (75) 1833—ab
  retentive for fractures of the clavicle, *1086
Appendectomy, in pus cases, (87) 1694
  with uncommon location of appendix involving a modification of intermuscular incision, (12) 1199
Appendicectomy, technic of, (26) 428, (31) 1449
Appendices of unusual size, (51) 812—ab
Appendicitis, (118) 876, (145) 877, (81) 881—ab
  and pregnancy, (29) 134, (85) (89) 741—ab, (53) 816—ab, (112) 1120
  bacteriology of, (28) 1121
  cases treated on Long Island, (9) 808—ab
  clinical and operative phases of, (92) 426
  cure of, (88) 501
  diagnosis and treatment of, (86) 1279—ab
  diagnosis of, when appendix lies in the pelvis, (97) 813
  differential diagnosis between, and right pyosalpinx or salpingitis, (106) 1120
  diverticulum information in, (62) 1766
  earliest and complete removal of appendix, (55) 1029
  early operation in, (80) 79, (88) 1285, (103) 1370—ab, (59) 1912
  etiology and pathology based on clinical and bacteriologic examination of twelve cases, (137) 877
  etiology and treatment of, (87) 1834—ab
  experiences at Nuremberg city hospital, (64) 1766
  freak case of, (34) 494—ab
  gangrenous, (9) 1364
  importance of certain points in diagnosis and surgical treatment of, (86) 947
  in children, (19) 223—ab, (8) 1199—ab, (22) 1825
  in relation to pelvic disease, (89) 426, (74) 875—ab
  internal treatment of, (73) 1529
  in trained nurses, *22
  Maragliano on, (75) 362—ab
  medical and surgical, (16) 575—ab
  moment for operating in, (34) 360
  mortality of, (36) 1201
  necessity for early operation, (105) 659
  notes on, (131) 497
  one possible cause for, (95) 1524
  pathogeny of, (27) 815
  pin worms as a cause of, (81) 496, (6) 2030—ab
  prevention of, (73) 226—ab
  problems in, cases, (81) 1119
  prospects ond vicissitudes of, (1) 498—ab
  quiescent period, (19) 1121—ab
  review of year's work in, (4) 1443—ab
  simulation of, by cholelithiasis, (25) 494—ab
  successful use of adrenalin chlorid solution in, (88) 813
  suppurating, (93) 1447
  surgical treatment of, (107) 1524
  study of records of 155 cases of operation for, (26) 1282
  traumatism as exciting cause of acute, (9) 1989—ab
  treatment in percarious stage, (8) 133—ab
  treatment of individual in, (14) 656
  typhoid, without other intestinal lesions, (66) 875—ab
  when to operate, (76) 1609
  zigzag incision in, (48) 1612—ab
Appendicostomy, (66) 356—ab, (10) 1448
  and cecostomy in treatment of chronic colitis, (21) 809—ab
Appendix, condition of patients after removal of vermiform, (14) 2032
  cyst formation in relics of, (68) 1992
  inflammatory conditions of, accidentally brought to light in pelvic operations, (39) 355—ab, (73) 875—ab
  invagination of, (30) 1909—ab
  its relation to pelvic disease, (129) 1364
  malposition of, as cause of functional disturbances of intestine, (42) 1201—ab
  nail in, (68) 1762
  question, (46) 78—ab
  reasons for removing, when abdomen is opened for other lesions, (75) 875—ab
  relation of, to pelvic disease, (72) 875—ab
  resection of, (54) 1992
  spontaneous gangrenous formations in the vermiform, (5) 1364
  vermiformis, (34) 1201
  vermiformis, transmesenteric hernia of, (45) 738
Apex, to designate location of, (70) 226—ab
Arctics, medical affairs in heart of the, *1564, *1647
Army, medical service of an, in modern war, (44) 73
Arsenic, test for, poisoning, (80) 141—ab
Art, literature and pseudoethics, mixoscopic adolescent survivals in, (95) 1031
Arterial changes, importance of early recognition of, and of chronic vascular hypertension in relation to life insurance, (87) 1828
  pressure in disease, (77) 362—ab
Arteries, experiment affections of, in rabbits, (61) 293
  extirpation of external carotid, with branches, for cure of certain malignant growths, (102) 427
Arteriosclerosis, (6) 574—ab
  affecting nervous system, (4) 871—ab
  clinical course of, and chronic vascular hypertension, (102) 876
  cortical cerebral, with distinct focal symptoms, (33) 134
  current theories regarding causation of, (18) 743
  ending in cardiac insufficiency and acute glosso-labiolaryngeal paralysis, (119) 1280
  etiology and pathology of, (117) 1031
  in relation to diseases of nervous system, (65) 136
  preliminary communication on treatment of, (29) 878—ab
  treatment of, (83) 1209—ab
Arteritis, peripheral obliterating, as cause of triplegia following hemiplegia and of paraplegia, (52) 424
Artery, aneurism of pulmonary, (49) 743
  aneurismal dilatation of right subclavian, innominate and first part of common carotid, (16) 1204
  diagnosis of rupture of middle meningeal, (96) 1280
  embolism of pulmonary, (76) 1768—ab
  ligature of innominate, (13) 1448
  ligature of profunda femoris, common femoral artery and common iliac artery on same side, (6) 1448
  pathologic conditions of basilar, (74) 1767—ab
Arthritis, deforming chronic rheumatic, (66) 1694
  serum treatment of pneumococcus, (106) 1125—ab
Arthrotomy, new method of, for old dislocations of shoulder, based on experience in radical breast removal, (44) 1987—ab
Asepsis, observations on, in general surgery, (54) 1988—ab
Asiatic blood fluke, second Chinese case of infection with, (7) 1198
Asphyxia, intubation in, (85) 1913—ab
  traumatic, (36) 1118, (9) 1908
Aspiration in diseases of ear and nose, (15) 814—ab
Astasia, acute, consecutive to non-diphtheric angina, (26) 2033
  abasia, early American description of ,(94) 1031
  treatment of, (27) 661—ab
Asthenopia due to latent hyperphoria, (12) 1276—ab
Asthma, (7) 808—ab
  food factor in, (27) 1028, (20) 1116
  prognosis of, from digestive blood, metabolic etiologic standpoint, (102½) 947
  treatment of, (105) 813
  treatment of attack in spasmodic, (8) 1989—ab
  vasomotor pathogenesis of bronchial, (70) 362—ab
Astigmatism cause of vomoting in school children, (14) 809—ab
  etiology of, (69) 946
  experimental and clinical evidence of dynamic (spastic), *613
Asylum, new insane, (116) 666
Asylums, children's, (131) 745, (85) 501
Asymmetry, facial, as a possible cause of deformity of nasal septum, (106) 1280
Ataxia and vertigo in cerebral-extracerebral lesions, (144) 746
  family, of hereditary-cerebellar form, with necropsy, (158) 498
  of central origin appearing in childhood, *1075
  tabetic foot as factor in, of lower extremities in tabes dorsalis, *1840
  vertigo in brain lesions, (104) 1125
Atelectasis, pulmonary, in adults, (3) 1524—ab
Atlas, dislocation forward of, with fracture of odontoid process of axis, (41) 738
  forward dislocation of, in man of megalithic age, (22) 815—ab
Atoxyl injections in lichen ruber following planus, (73) 500
Atrophy, etiology and dietetic treatment of infantile, *579
  family of peroneal type, (64) 1030
  infantile, (69) 1207, (37) 1764
  progressive muscular, (126) 877
Atropin and hematropin, clinical study of relative actions of, as cyclopegics, (59) 657
  misuse of, in eye diseases, (47) 1446
Auditory affections in school children, (108) 364—ab
Aural conditions of special interest to general practitioner, (131) 1364
Auricle, congenital malformation of left, and of external cutaneous canal, *1799
Auscultation, rod, (13) 1026—ab
Autoinfection, diathesis of, (31) 1990—ab
Autointoxication, (117) 1204
  acid, in infancy and childhood, (76) 1119
  after laparatomies, (97) 1125—ab
  and infection, (100) 1908
  as factor in mental diseases, (86) 1120
  eye affections and, (49) 1699—ab
Autolysis in puncture fluids, (64) 362
Autopsies, clinical value of, (36) 219
Auto-serotherapy, (131) 1448
Atheroma, causes of, (97) 227
Athetosis, treatment of cerebral palsies and, by nerve anastomosis and transplantation, (66) 136
Atrophy, hereditary progressive muscular, spinal and bulbar, (35) 134—ab
Avulsion of terminal branches of trigeminal nerve for trifacial neuralgia, (13) 1985—ab

and its treatment, (102) 1120
experience with serum treatment in, (54) 1202—ab, (1) 1829
further contribution to pathogenesis of, (27) 1606—ab
medical treatment of, (153) 660
mortality of operations other than strumectomy, with special reference to gynecologic operations, (39) 944—ab
pathologic anatomy of, (67) 875
review of end results in cases of, treated surgically, (25) 1533—ab
rhythmic movements of head in, (54) 500—ab
serotherapy of, (36) 1990—ab
serum of thyroidectomized sheep in, (74) 79
surgical treatment of, (154) 660, (34) 73
thyroid treatment, (70) 952
treatment of, (75) 79, (89) 1609
Exophthalmos caused by disease of ethmoidal cells and frontal sinus; drainage; recovery, (115) 497
Experience, what, has shown, (76) 947
Expert, medical, (130) 659
Extension, apparatus for manifold, (84) 501
Extensor plantar reflex, new method of eliciting, and its spinal localization, (11) 288—ab
External rectus muscle, injury resulting in cutting of, and probably laceration of optic nerve, (77) 136
Extirpation, alterations following, of superior cervical ganglion, (75) 136
Extramedian symphyseotomy, (89) 295
Extremities, conservative surgery of, (91) 1524
Extremity, deformities of lower, (2) 942—ab
Exudates and effusions, differentiation of, (110) 1126—ab
experimental production of lymphocyte, (115) 143—ab
postoperative pelvic, *1622
Eye, accessory apparatus for locating foreign bodies in, (87) 136
action of external muscles of, and diagnosis of ocular paralysis, (18) 1908
affections and autointoxication, (49) 1699—ab
affections, of dental origin, (8) 1120
affections of, due to autointoxication, (72) 1993—ab
and ear work, (84) 1828
blasting injuries, *387
cases demanding removal of, of interest to physician and surgeon, (75) 1908
comparative anatomy of, (107) 1447
congenital paralysis of abducens of, with convergent squint of other, (59) 946
conservative treatment of severe injuries of, (59) 1908
defects associated with puberty, (9) 1444—ab
diseases, diaphoresis in treatment of, (61) 74
diseases of, in infants, (39) 1764
diseases of, in relation to general practitioner, (85) 659
ear, nose and throat, progress of disease of, (127) 659
filtration of fluid of, when under influence of atropin or eserin, (8) 947
infection, second hundred cases, with bacteriologic examination, (72) 1524
inflammation of, due to toxins of gonococcus, *1926
injuries and their lesions, *389
injuries due to blows from corks of ginger-ale bottles, (14) 942
lesions, recognition of importance by general practitioner, (35) 355
major trauma of, in general practice, (61) 1608

Eye, methods for localizing foreign bodies in, by Roentgen ray, (112) 497
  paralysis of motor nerves of, in diabetics, (40) 1990
  shield for, in skiascopy, (114) 497
  simple conditions that should be familiar to every physician, (41) 1986
  strain, (68) 946
  strain and neurologists, (60) 1278
  strain, importance and limitations of, (16) 133—ab
  symptoms in medical diagnosis, (133) 1448
  technic of vaccination of, (94) 745
  traumatic lesions of, *391
Eyeball, indirect injury of, (108) 1447
  penetrating wound of, (46) 1907—ab
  spontaneous luxation of, (65) 1451—ab
Eyeballs, importance in diagnosis of paralysis of associated movements of, (105) 1031
Eyelid, tine of steel fork thrust through left upper, eyeball and antrum of Highmore, (104) 1447
Eyelids, ablepharia partialis of upper, (63) 946
Eyes, protection of, in automobiling, (19) 428—ab
  systematic examination of, of defectives, (5) 574
  systematic examination of school children's, (83) 1524
  what every doctor ought to know about, (111) 813

Miller, De Laskia, a memorial address, (66) 1203
Mind and body, facts and fancies about, (27) 423
Mineral springs, radioactivity of, (64) 500
Mirfeld, John (1393), and medical study in London during the middle ages, (8) 1908
Mitoses in cells of the Graafian follicle, (14) 1694
Mitral incompetency and ascites treated with apocynum cannabinum, (20) 1365—ab
  insufficiency, dynamics of, (61) 743
Modalities, importance of differentiation in use of electric, (9) 1275
Molluscum contagiosum, virus of, (92) 1834
  fibrosum, (29) 1282—ab
Monochloracetic acid, nasofibroma treated by injections of, (89) 74
Monster, case of anencephalic, (16) 1525
Mont Blanc, laboratory on summit of, (27) 1033—ab
Moral emotions, are, able to induce organic nervous affections? (35) 816—ab
Morgagni to Virchow, an epoch in the history of medicine, (24) 1606, (16) 1763
Morphin, experimental immunization to, (89) 501—ab
  habit, hyocin hydrobromate in treatment of, (37) 657—ab
Morphin-scopolamin, narcosis, death from, (60) 816
Mortality, infant, in Michigan and Detroit, with an inquiry concerning normal infant mortality, (40) 1826
  infantile, (32) 1764—ab
  lessening of infant, (85) 817
Mosetig bone filling, modification of, (65) 362
Mosquito as etiologic factor in disease, (83) 1203
  elimination of, *585
  fever, (77) 881
  is, a disseminator of malaria? (111) 427
  only etiologic factor in malaria, (59) 1447
  transmission of disease by, *90
Mosquitoes and disease, (61) 1363
Mother, hygiene of, before birth of child, (26) 1764—ab
Motor functions, spinal localization of, (92) 882—ab
  lesions, differential diagnosis between central and peripheral, by electricity, (112) 1364
Mound-builders, bones study of pathologic changes in some, from Ohio valley, with reference to syphilis, (55) 73
Mouth, effect of lesions of, on other organs and on system at large, (80) 1908
  gag, combined, and stomach tube protector, *1573
  medical relations of certain conditions of, *515
  surgical bacteriology of, *458
  treatment of suppurative affections of face and neck, emanating from, *374
Mucous colic or membranous colitis, (47) 1608
  zone of epithelium of stomach and intestine before and after birth, (27) 743
Multiple neuritis, *1779
Murphy button, obstruction of, by olive stone or scybala, (69) 362
  button obturator and applicator for, *853
Muscle, fatigue of cold-blooded compared with that of warm-blooded animals, *1776
  origin of congenital tumor in sternomastoid, (56) 225—ab
  sense, loss of, in fingers of both hands, with intact sensibility of muscles in hand and forearm, (31) 77
  transference (20) 1276—ab
Muscle, varying elasticity of uterine, (60) 1284—ab
Muscles and joints, determination of sensibility of, (60) 952 ab
  hypertrophy of, in toxic polyneuritis, (96) 1210—ab
  paralysis of abdominal, (53) 1911
  recurrent paralysis of ocular, associated with pain, (95) 497
  traumatic ossification of, (49) 293—ab
Muscular palsies, advances in treatment of, (127) 1364
Musculus rectus inferior, (42) 1122
Mushroom intoxication, antitoxin for poisonous, (27) 1446-ab
  poisoning, three cases of, (117) 876
Myasthenia cordis, (55) 500—ab
  gravis, (164) 498
  gravis, rapid general, (12) 223—ab
Mycosis fungoides and x-ray, (45) 1827—ab
  fungoid and leukemia, (75) 226—ab
  fungoid, with multiple deep ulcerations treated and cured with soluble toxin of erysipelas streptococcus, (50) 1450
Myelitis transverse, lumbar, acute, (73) 79
Myelocytes, treatment of, in children's blood, (75) 664-ab
Myocarditis, rheumatic, (77) 1833—ab
  vascular affections and, in children, (76) 1833—ab
Myofibromata, uterine and visceral degeneration, (12) 1521
Myoma and menopause, (56) 880—ab
  of esophagus, *2008
  operations, indications for, (84) 1124—ab
Myomata, malignancy in uterine, (31) 1360
  removal of, during pregnancy and delivery, (97) 1210—ab
Myopia operation, (48) 816
  progressive, (72) 79
  progressive axial, *607
  treatment of, (71) 79
Myotonia, case of, (36) 134—ab
  partial, in occupation paralysis, (50) 1528—ab
  syndrome of, (31) 1910—ab
Mysophobia, (47) 1827
Mystery, a metastatic, (7) 2032
Myxedema, case of, with thyroid feeding, (87) 1524
  congenital, (62) 1451—ab

N

Narcolepsy, (144) 660
Narcomania, morphinomania, cocomania and general, and some of their legal consequences, (75) 74
Narcosis, (59) 500
  ideal dental, (15) 1539
  pulmonary, by tube through mouth, (74) 1284
  short, short incision and short stay in bed after ideal operations, (2) 2030—ab
Nasal occlusion in its etiologic relation to general diseases, (140) 497
  septa, submucous resection of deflected, *34
  septum, deflections of, critical review of methods of their correction by window resection, (58) 741
  septum, submucous resection of, new technic with author's swivel knife, (67) 741—ab
  septum, submucous window resection of, (66) 741—ab
  sinus disease, general practitioner's diagnosis of, (107) 358
Nasofibroma treated by injections monochloracetic acid, (89) 74
Nasopharynx, syphilitic manifestations in, ear and buccal cavity, (41) 1522
National guard regiment, experiences of a, in connection with combined regular army and national guard maneuvers at Manassas, (107) 947
  guard, surgeon of, (109) 947
Nature, relation of man to, (94) 222
Naval medical school, United States, (79) 221
Neck, woody phelgmons of, (69) 1528
Needle-holder, an improved, *329
Negri bodies in rabies, (65) 744—ab, (66) 744—ab
Neoplasm, canine, (48) 134
Neoplasms, plea for early routine extirpation of all, (70) 1828
Nephrectomy, fatal reflex anuria after, (69) 1912
  for cancer, (34) 139—ab
  indications and contraindications for, (111) 666—ab
Nephritis and hematuria, (26) 1826, (25) 1906
  chronic interstitial, (34) 1277
  chronic, with special regard to transformation of nitrogen, (45) 2034—ab
  elimination of chlorids in, *1915
  hexamethylenamin for scarlatinal, (37) 662—ab
  hitherto undescribed change in urine of patients suffering from, (7) 1989—ab
  medical treatment of, (11) 872—ab, (78) 1908
  ocular manifestations of chronic, (77) 1908
  organ treatment of, (38) 1450—ab
  scarlatinal, (89) 1524
  studies on, (90) 882—ab
  study of relationship between arterial hypertension and indicanuria in, (2) 1274
  surgical treatment of chronic, (128) 1031
  treatment of, recent views regarding, (5) 354—ab
  treatment of chronic interstitial, (108) 1120
  tuberculous, (50) 657—ab
  with complete absence of chlorids, (35) 1910—ab
Nephroptosis, new operative treatment, (36) 423—ab
Nephroureterectomy, (107) 1203
Nerve grafting in spinal paralysis in children, (45) 663
  position of, in fracture of upper arm, (89) 1768
Nerves, an investigation on regeneration of, (104) 1031, (5) 1204—ab
  conservation of parietal motor, in abdominal section, (46) 874—ab
  experimental study on regeneration of peripheral, (104) 1031
  historical sketch of, of female genitals, (37) 874
  hypoglossal suture of, (73) 1368
  regeneration of, (55) 1612—ab
  resection of, in painful gangrene, (34) 878—ab
  secondary suture of, (67) 1699
Nervous affections after electric accidents, (77) 294—ab
  and mental diseases, progress in, (101) 427
  and mental diseases, wards in general hospitals for acute, (156) 660
  disease, suggestions concerning treatment of some common forms of, (109) 742
  diseases, general treatment of, (96) 222
  diseases, study of contractures in organic, and their treatment, (91) 1203
  diseases, true nature of functional, (27) 1277
  subjects, treatment of, in mountains, (88) 1453—ab
  system, derangements of, causing male sterility, (34) 355
  system, diagnosis of diseases of, (14) 1027—ab
  system, education and hygiene of, (34) 809, (35) 874, (31) 944
  system, progress in diseases of, (128) 659
  system, slight errors of refraction and their influence on, (14) 137
Neuralgia, aural, of dental origin, (88) 74
  avulsion of terminal branches of trigeminal nerve for cure of trifacial, (13) 1985—ab
  trigeminal, (38) 134
Neuralgias, treatment of some, by Roentgen rays, (2) 288-ab
  three cases of trifacial, due to intranasal causes and treated successfully by intranasal methods, (51) 1522
Neurasthenia, *21
  among the working classes, (71) 226—ab
  bicycle in treatment of sexual, (36) 662—ab
  cholemia in, (4) 353—ab
  history of, (40) 1450

Neurasthenia, mental symptoms of, (13) 422
  peculiar case—perhaps, *194
  physical therapy of, (73) 1832
  psychotherapeutics of, (57) 740
  reflexes and tremor in, (93) 364—ab
  static electrical treatment of, (89) 358, (99) 659
  study on etiology; treatment by occupation, (18) 354—ab
  traumatic, (143) 660
  treatment of, (88) 358 (98) 659
Neurasthenics, educational treatment of, (131) 358
Neuritis, ascending, (56) 740
  ascending pneumococcus, (93) 1530—ab
  multiple, and diabetes mellitus, (84) 1524
Neurological clinic, report of, of Professor Collins, (42) 134
Neurology, modern, (108) 1031
Neurone theory by the latest authorities, (87) 1203
Neuropsychoses, borderland of, (82) 1031
Neuroses, cardiac, and superposed dilatation, (67) 1451—ab
  certain types of association and habit, (132) 947
  of early life, (8) 577
  traumatic, (81) 1031
Neurosis, cardiac, necessity of its proper diagnosis, (22) 944
Nevus pilosus pigmentosus and other skin lesions treated with liquid air, (12) 288
  vascular, warty, of face, (54) 1034
Newborn, gastroenteric intoxication in, (75) 1694
  hemorrhagic disease of, (77) 741
  tetanus of, with report of three recoveries, (117) 222
Newfoundland—climate and physical geography, (120) 1448
New Mexico, visit to, (124) 358
Nicholson, extracts from diaries of Bishop, (17) 1984
Nicotine intoxication, contribution to study of chronic, of the nervous system, (22) 809
Nitric acid, effects of inhalation of fumes of, *396
Nitrogen, determination of organic, in sewage by Kjeldahl process, (68) 813
  volume of, evolved from uric acid by action of alkaline hypobromite solution, (59) 1363
Nitroglycerin, use of, (42) 361-ab
Nobel, Alfred Bernard, (87) 1031
Nocht's stain, method for preparing permanent, (149) 497
Noma, differentiation of, (89) 1994—ab
  surgical treatment of, (66)663
Non-gastric diseases, certain, with gastric symptoms, *1387
Nose, (129) 947
  adenocarcinoma of, Killian operation for radical removal of, (90) 74
  and its accessory sinuses in American bear, (59) 741
  and pharynx, syphilitic manifestations in, (33) 1277—ab
  and throat, syphilitic lesions of, (134) 877
  massage of, in hay fever, (90) 227—ab
  ocular symptoms of affections of the accessory sinuses of, *747
  syphilis of, and accessory sinuses, (40) 1522
Noses, correction of abnormally large, (81) 1037—ab
Nostrum evil, secret, *1701
Nothnagel's *last notes on* his stenocardiac attacks, (39) 1697
N-rays, (76) 362
Nourishment, lack of sufficient, in dyspeptic and nervous persons, (54) 1450—ab
Nuck, cyst and hydrocele of canal of, (28) 494
Nucleus, defect in, (78) 1453
  phagokaryosis, new action of cell, (46) 951—ab
Nurse, her place and equipment, (130) 1031
  trained, and doctor, (107)1031
  true, (147) 660
Nursing, breast, (52) 500
  breast, in Leipsic, (88) 1209
  necessity of medical supervision in breast, (27) 1366—ab
  to promote breast, (66) 500
Nutrition, importance of study of, (2) 1690—ab
Nutrition, recent advances in physiology of human, *1381
Nystagmus, unilateral and other unusual forms of, (119) 742

O

Obesity, reduction treatment of, *1984—ab*
  treatment of, in children, (69) 817—ab
Obstetric, cases, three, (49) 424
  practice, practical points in, (76) 1762
Obstetrics, aseptic, (87) 1447
  normal, (119) 427
  normal, management of puerperium, (140) 1364, (96) 1609
  normal, physiology of puerperium, (106) 813, (116) 947
  normal, diagnosis and management of labor, (54) 134
  Viardel's treatise on, (41) 944
Occlusion, mesenteric, (152) 660
Occupation in therapeutics of nervous affections, (61) 431—ab
Ocular palsy, two cases, in which paralysis was probably dependent on lesion in neighborhood of sphenoidal fissure, (77) 74
Officer, medical, in campaign, (50) 1277
Oil of wintergreen, poisoning from, (53) 657
Olive oil in affections of stomach and duodenum, (64) 1036—ab
  oil, large amounts of, in treatment of stomach affections, (39) 224—ab
Omentopexy, new danger of, (77) 1700—ab
  subcutaneous, (71) 1452—ab
Omentum, cystic tumor of, (10) 1364
  fibroma of gastrohepatic, in lesser peritoneal cavity, (58) 1828
  intra-abdominal torsion of, (69) 1992
  [illegible]tance of [illegible] of, (97) 882—ab
  torsion of great, (61) 875
Onomatologia gastrologica, (36) 355
Onychitis, chronic pyogenic, cured by the x-ray, (44) 874—ab
Oöphoritis, chronic, (55) 663
Operating room, extemporized, (79) 356
Operation, adenoid, on child and practical observations in regard to it, (83) 1119
  indications for, (8) 223
  in patient's home, (17) 422—ab, (134) 1364
  on palate, influence of intercurrent diseases on, (29) 949—ab
  peculiar symptoms following radical, *1488
Operations, advantages of performing capital in selected cases without anesthesia, (90) 1203—ab
  how far shall we go in performing multiple, at one sitting? (30) 219
  law of consent in regard to, (37) 576
  private house, (17) 422—ab
  report of, performed at public clinics during session of 1904 05, (24) 354
Operative cases, after-treatment of, (55) 1694
Ophthalmia, constitutional aspect of sympathetic, (76) 136
  gonorrheal, with involvement of anterior ethmoidal cells, (70) 136
  neonatorum, treatment of, (37) 219, (83) 1762
  what means does modern obstetrician employ to prevent, of newborn, (10) 1199—ab
Ophthalmic practice, study of failures in, (20) 1200—ab
Ophthalmology, Arabian, *1127
  in Zurich and Munich, (167) 660
Ophthalmoscopy, simple device for, devised to meet conditions on board ships, but capable of general application, (24) 1985—ab
Optic disc, is physiologic cupping of, not confined to center? (90) 659
  nerve, indirect injuries of, (2) 427
Optic disc, papilla, anomalies of vascular system of, (85) 136
Optometrist, is, legally and scientifically qualified to practice medicine (49) 73
Oral sepsis as cause of iritis, (14) 577—ab
  sepsis, relation of, to dysentery, (15) 660
Oration, annual, (101) 74
Orbit, osteoplastic resection of external wall of, (34) 1697, (89) 1834
  phlegmon of, (70) 1908
Orchidopexy in inguinal cryptorchismus, (46) 224
  new method of, (7) 655—ab
Organisms, simple technic for enumeration of, in fluids, (13) 223—ab
Organization, medical, (67) 1278
  medical, helpful in promoting social status of physician, (83) 1279
Organotherapy, oil extracts in, (135) 746
Organs, displacement of abdominal, (8) 1984
  transplantation of, *1645
Oriental sore, (116) 745
Orientation, disturbances in, (122) 666
Orthopedic affections, early diagnosis of, and its importance, (47) 361
  surgery, present status of, (72) 1447
Os lunatum carpi, luxation of, and its treatment, (44) 950
  navicularis tarsi, apparent fracture of, (63) 1206
  penis, fracture of, in otters, (13) 359
  prevention of dilatation of external, (61) 1368—ab
Ostealgia, thoracic, (45) 1992-ab
Osteitis deformans, case of, (98) *1209*
Osteology and general practitioner, (96) 876
Osteomalacia, (100) 74
Osteoma of orbit and upper jaw, (65) 1523
Osteopathy, (147) 877
Osteopsathyrosis, idiopathic, (66) 1528, (67) 1613—ab
Otitis, artificial hyperemia in treatment of acute suppurative, (66) 880—ab
  scarlatinal, (50) 945
  symptomatology, of acute in children, (30) 289
Otitis-media, acute purulent, complicating typhoid, (50) 1522
  chronic purulent, with meningitis, (93) 813
  early diagnosis and treatment of, (92) 221
  mucosa, (64) 741
  purulenta, pyoktannin in treatment of chronic, (48) 1522
  study of disturbance in acute perforative, (71) 1203
  suppurativa, two cases of acute, caused by diplococcus intracelluaris of Weichselbaum, followed by mastoiditis and meningitis, (99) 427
  treatment of acute, (101) 222, (116) 742
  treatment of infected, (5) 736
Ovarian conditions, reflex, their causes, (148) 877
  transplantation, (9) 1199
Ovaries, adenocystoma of, (41) 292
  and tubes, inferior of, and natural resistance, (130) 1448
  and uterus, conservation of, in operative procedures on uterine adnexa, (53) 1029—ab
Ovariotomy, twenty-two years' experience with, (82) 1124—ab
  vaginal, (64) 880—ab
Ovary and placenta, internal secretion of, (68) 225
  interstitial glands of, (40) 292
  resection of, (56) 1284—ab
  small hemorrhagic cysts in, (42) 1367—ab
  tumors, primary malignant degeneration of cystic, (73) 743
Ovum, corroding process of, in its implantation in Fallopian tube, a source of hemorrhage in tubal pregnancy, *1378
Oxygen, intravenous injection of, (91) 664—ab
Oxytocic medication, (41) 429-ab
Ozena, high-frequency currents in, (72) 362
  subjective, (4) 2030
  treatment of, by injections, (44) 428

P

Pachymeningitis, hemorrhagica, internal, (102) 1370
  hemorrhagica, with external hydrocephalus, (65) 817
Paget's-disease, (58) 951
  effect of Roentgen ray on, of gluteal region, (55) 135—ab
Pain as symptom in urinary diseases, (109) 497
  in chronic catarrh of stomach, (97) 296—ab
  origin of, in photophobia and blepharospastic syndrome, (38) 874—ab
  significance of sudden, severe, abdominal, (26) 576, (21) 656—ab
  value of, in gynecologic practice, (9) 1032
Pains, rheumatoid, following injuries in high altitudes, (115) 427
Palate, cleft, operation wounds, (4) 290
  operation for closure of cleft, in infants, (3) 290—ab
  operative treatment of cleft, and causes of failure, (7) 1026—ab
  technic of plastic operations on, (18) 76—ab
Pancreas, cysts of, (61) 657
  disease of, (15) 656
  genesis of adenocarcinoma of, (40) 743
  gunshot wound of, (46) 219
  seven cases of cysts of, (61) 1699—ab
  transverse laceration of, cured by suture, (66) 1766
  trypsin, single and specific nature of, (46) 1122, (60)1450
  work of, (19) 743
Pancreatic inflammation, recognition and treatment of, (15) 943—ab
Pancreatitis, acute, (19) 1605—ab, (66) 1908
  acute hemorrhagic, (12) 742, (19) 873, *2011
Panophthalmitis, sympathetic inflammation following, *525
Papaw, poisoning due to, *2013
Papyrus Ebers, medical features of, *1928
Paraffin in correction of deformities of nose, (109) 813
  injections by cold process, (53) 1608
  in surgery, (69) 356, (82) 876, (140) 877, (130) 1364, (71) 1828
Paraldehyde, value of, in treatment of insomnia, (6) 1689
Paralyses, laryngeal, and their diagnostic value, (4) 75
  orthopedic treatment of, (51) 951
Paralysis agitans, diagnosis, prognosis and therapy of, (19) 2032
  agitans, is, caused by defective secretion or atrophy of parathyroids? (14) 1905—ab
  birth, case of, (66) 79
  chronic of intercostal muscles as primary cause of dropsy, (25 1449
  contracted muscles of infantile, (19) 948
  diagnosis of ocular, (13) 2032
  diver's, (15) 1525—ab
  infantile, its nature and treatment, (40) 1028—ab
  left platysma, (39) 134
  obstetric, (114) 666
  outline of parental periodic, (93) 1524
  periodic, *1224
  postdiphtheritic, (70) 1447
  postgonorrheal, (61) 1451
  syphilitic spinal, with reference to type described by Erb, (8) 574—ab
  two cases of bilateral birth of lower-arm type, (14) 1444
Paralyzed muscles, surgical aids in treatment of, (12) 217-ab
Paraplegia, cure of spondylitic, (59) 1035—ab
  spastic, (40) 1446
Parasite, further note on form of malarial, found in and around Jerusalem, (25) 1909
Parasites, intestinal, in canal zone, *1955
  vegetable, of skin and modern methods of culture, (20) 133
Parasitism in man and animals, (104) 364
Parathyroid glands in exopththalmic goiter, (29) 1830—ab

Parathyroids, is paralysis agitans caused by defective secretion or atrophy of? (14) 1905-ab
Paratyphoid bacilli, agglutination of, by typhoid serum, (59) 431
  fever, (11) 1281
  fever, nature of, and allied infections, (57) 74—ab
  impossibility of differentiating so-called, from typhoid except by bacteriologic examination of blood, (15) 737—ab
  or paracolon group, carbohydrate reactions of, (25) 71
Parchment, reflections at majority of a, (23) 656
Pareses, occupation, (114) 745
Paresis, pathology of general, (94) 1120
  pseudospastic, (72) 1369—ab
  sixty cases of general, (9)1116
Paretic dementia, pathology of (34) 2032
Paris, general conditions of medical studies and of hospital administration in, (3') 75
  hospital, delirium patients in, (33) 878
Parotitis, chronic, (106) 666
  due to pneumococcus, (14) 813
  pathology and prevention of secondary, (13) 1609—ab
  primary suppurative, (19) 1204
Pars iridica retinæ, cysts of, (84) 136
Passages, paraurethral, origin of, in male, (95) 745
Patella, forty consecutive cases of fracture of, treated by wiring, (13) 1281—ab
  fracture of, *403
  fractures of, (81) 1524, (52) 1608
  habitual luxation of, (63) 743—ab
  results of suture of bone in fractures of, (94) 295
Patent medicines, infamy of, (84) 1363
Patents of interest to physicians, (96) 1834
Pathologist and surgeon, *149
Pathology, surgical, (95) 1280
Patients, clinical chart for records of, in small hospitals, *920
Pediatric clinic, a model, (62) 817—ab
Pediatrics, aims of modern, (77) 817
  past, present and future, (119) 876
  practical points in, for general practitioner, (9) 736—ab
  teaching of, *507
Pellagra, (70) 743
  geographical distribution and etiology of, (12) 1829—ab
Pelvic examinations, technic of, and principles of pelvic medication, (6) 942—ab
  floor, choice of operation for restoration of, (162) 498
  floor, primary repair of lacerations and injuries of, (118) 497
  floor, spoon elevator for raising, (5) 498
  operations, intestinal obstruction after, particularly after supravaginal hysterectomy, (14) 743—ab
Pelvimeter, improved, (46) 1527
  new, (66) 226—ab
Pelvi-peritonitis, (146) 746—ab
Pelvis, does large head justify operation to enlarge? (61) 1283
  dynamics of female, with reference to malpositions of uterus and their treatment, (122) 742
  enlarging, by pubiotomy, (26) 1366—ab
  fractures of, (57) 1612—ab
  impalement injuries of, (63') 1766
  mechanics of female, (94) 1286
  plastic reproduction of solid floor of, (75) 1452
  spinal anesthesia with elevated, (42) 1910—ab
  study of bony, in 150 cases, *1709
  support for, (52) 1992
Pemphigus, acute malignant,(68) 658
Penis, accessory passages of, (55) 1206
  and scrotum, elephantiasis of, (54) 1206
  complete extirpation of, for epithelioma in Hawaiian; recovery, (17) 1365
Penis, deformities in passages in, (72) 1699
  successful amputation of, for epithelioma, *1954
  technic of amputation of, (47) 224
Pentosuria, (42) 2034—ab
Peptic ulcers, after gastroenterostomy, causing gastrocolic and jejunocolic fistula, (14) 288
Peptone nitrate and nitrate content of Witte's, with reference to influence on demonstration of Indel and cholera red reactions, (46) 1028
Perforation, intestinal, in typhoid fever, *1714
  intestinal, in typhoid in early life, (31) 1692—ab
Periarteritis nodosa, (69) 1613
Pericarditis, acute, complicating acute lobar pneumonia, (45) 1361—ab
  relations between, and valvular lesions of aorta, (76) 1700—ab
  surgical treatment of, with effusion, (119) 666—ab
Pericardium adherent, (68) 74
  procedure for opening, (46) 1119—ab, (39) 1692
Perineal lacerations, duty of physician to patients with, *326
Perineorrhaphy, new method of, (32) 1360—ab
Perineum, care of, with description of new method of delivery of shoulder, (12) 872—ab
  method of guarding, in labor, (8) 1204—ab
  repair of, *1462
  secondary operation for complete rupture of, (15) 577-ab
Peritoneum, origin of "implantation" tuberculosis of, and relation to inflammation, (54) 362
  physiology and pathology of, (41) 78—ab
Peritonitis, abdominal incision for tuberculous, (11) 1521
  acute diffuse suppurative, *620
  cure of tuberculous with local injections of iodoiodid solution, (88) 362
  defenses against bacterial, (65) 1368—ab
  drainage in acute, diffuse septic, (121) 1280
  fulminating, complicating pregnancy, due to ruptured pus tube at eight and one-half months, (16) 422
  general, due to perforative appendicitis, (7) 358
  laparotomy and drainage for puerperal, (45) 951—ab
  laparotomy in tuberculous,(55) 1035—ab, (86) 1768—ab
  malarial, (44) 1206—ab
  operative treatment of diffuse septic, (41) 2034—ab
  pneumococcus, (43) 1367—ab
  recurrent tuberculous, after incomplete operation, treated by x-rays, (21) 576—ab
  review of tuberculous, (60) 1523
  spontaneous healing of tuberculous, (39) 816
  surgical treatment of, (49) 429—ab
  treatment of, (76) 1694
  treatment of, diffuse and general, (42) 78—ab, (126) 1448, (7) 1604—ab
  tuberculous, treatment of, (86) 1614—ab
Perityphilitis, diagnosis and therapy of, (47) 663
  occlusion and stricture of intestine following, (90) 1285
  operative treatment of, (56) 1612
  semidorsal position in operation for, (89) 745
  treatment of chronic, (49) 816—ab, (52) 816—ab
Permanganate of potash, snakebite treated by incision and application of, (38) 1830—ab
Pernicious anemia, etiology and pathogenesis of, (171) 498
  malaria, postmortem disappearance of parasite, (6) 1823
Personal injury cases, examination and consultation in, (115) 1364
Pertussis, bacteriology of, with reference to agglutination of patient's blood, (137) 659
  treatment of, in relation to etiologic factors, (12) 422—ab
Peru, balsam of; origin of malignant growths, with note on treatment of malignant ulcerations by, (67) 356
Perverts and inverts, medicolegal consideration of, (108) 659
Pessary, ball, (80) 1613
Peter's method, exstrophy of bladder successfully treated by, *890
Pfeiffer's glandular fever, five cases of, *401
Phalanges, fracture of finger,(77) 1284
Pharmacology and therapeutics of ice, (4) 137
  contributions of, to physiology, (65) 1908
  United States, *708
Pharmacopeia and physicians, *1869, *1950
  for infants, (41) 1764
Pharmacy and pharmaceutical chemistry, progress of, (25) 291
  ethics of, *180
Phenomena, new clinical, (41) 810—ab
Phenylhydrazin, reaction of, with other substances than dextrose occurring in urine, (9) 359—ab
Philippine fever, a, *1323
Phimosis, its treatment by a new technic, (52) 1987—ab
Phlebectasia, (31) 743
Phlebitis, causes of femoral,(136) 497
  following abdominal and pelvic operations, *1792
  recurring of obscure origin, (172) 498
  treatment of, (50) 879—ab
Phlebosclerosis, peripheral, (3) 1275—ab
Phlegmon, woody, (77) 664, (89) 1453, (69) 1528
Phobia, clinical observation on rare case of, (53) 355
Phobias, organic origin of certain, (47) 140—ab
Photometric method, practical for case record, (30) 1760—ab
Photo-salve treatment, (82) 1453—ab
Phototherapy, (37) 1034
  compression in, (22) 359
  with ultraviolet rays, (81) 294
Phthiriasis, (2) 492—ab
Phthisis, albumosuria of, *1862
  fever of, etiology, sequels and treatment, (73) 221
  mixed infection of, (72) 221
  Rand miner's, (2) 1524—ab
  sanatorium treatment of, (5) 137—ab
  special symptoms in, (73) 1762
Physical health, necessity of, in acquiring an education,(112) 222
Physician and community, (92) 813
  and patient, (71) 496
  as a dentist, *514

Pseudokousma, (54) 495
Pseudoleukemia cured by Roentgen rays, (92) 501
Pseudopterygium and symblepharon relieved by Thiersch grafts, (105) 1447
Pseudosclerosis, (diffuse sclerosis), *1455
Psoriasis and salve tights, (30) 1990—ab
Psychiatry, outlines of, in clinical lectures, (91) 1031
Psychic states, suggestions on treatment of morbid, (27) 494
Psychics in the practice of medicine, (85) 1031
Psychology, study in abnormal, (23) 873, (23) 1027—ab
Psychoneuroses, psychopathic manifestations of in non-insane, *1711
Psychoses, beginnings of, (14) 575
  posttraumatic, (53) 952—ab
Psychosis, combination of, and cutaneous affection, (72) 141—ab
  Korsakoff's, (9) 217—ab
Pterygium, (54) 1907
  and pinguecula, etiology of, (58) 1699—ab
  of bacilli, (20) 138
Ptosis and operation of Motais, (87) 426, (61) 946
  visceral—its surgery, (40) 1986
Pubiotomy, (32) 499—ab, (26) 1366—ab
  extramedian symphyseotomy or, (48) 1911—ab
Public health science, relations of to other sciences, (1) 69
  health services, state and federal, (7) 1275—ab
Puerperal convulsions, case of, in which cesarean section was required, (23) 1692—ab
  fever as seen by general practitioner, (80) 1694
  fever, diagnosis of, (107) 876
  infection, treatment of, (33) 361—ab, (106) 876
Puerperium, high range of normal temperature and pulse throughout, (2) 1280
  influence of, on tuberculosis, (33) 1526
Pulmonary diseases, routine procedure of clinic for treatment of communicable, of New York Department of health, (9) 2031—ab
  tuberculosis as obstetrical complication, *1067
Pulse, changes in, when counted aloud, (45) 140—ab

Pulse, permanent slow, (105' 1125—ab
  unilateral paradoxical, *1405
  unusual case of intermittent, (71) 1992
Pupil, a congenital absence of dilator of, (10) 947
Purpura, (151) 660
  hemorrhagica, chronic, *107
  hemorrhagica, occurring during pregnancy, (5) 1824—ab
  infectious, (12) 1281
  infectious idiopathic, (79) 881—ab
  rheumatic, in children, (13) 218—ab
Puru or yaws, methods employed by Kelantan Malays in treatment of, (22) 1205
Pustule malignant, (107) 364
Pyelonephritis and ulcer of esophagus, complicating pregnancy, (19) 1984
  in pregnancy, (89) 1124—ab
Pyemia, ligation of ovarian and hypogastric veins in puerperal, (55) 1911—ab
  operative treatment of puerperal, (53) 880—ab
  portal, and pylephlebitis, (5) 1989—ab
Pylorectomy and partial gastrectomy—posterior gastro jejunostomy recovery, (18) 359
  for cancer, (36) 950—ab
Pyloric spasm and tetany, (42) 429—ab
Pyloroplasty and gastroenterostomy, (43) 220—ab
Pylorospasm, rebellious, (96) 1453
  with hypersecretion and tetany, (74) 1912
Pylorus, clinical features of benign stenosis of, (21) 423--ab
  congenital hypertrophic stenosis successfully treated without operation, (9) 877—ab, (20) 1204
  congenital stenosis of, (89) 954—ab
  etiology, diagnosis and treatment of benign stenosis of, (13) 288
  gastrojejunostomy for benign stenosis of, (3) 1026—ab
  gastroenterostomy for benign strictures of, (17) 138—ab
  hyperplasia of congenital, (41) 743
  hypertrophic, stenosis in infant, (37) 738
  situs transversus and atresia of, (50) 495
  stenosis of, in infant, (35) 1826—ab
  tuberculous stenosis of, (41) 1121—ab
  two cases of spasm with hypertrophy of, in infants cured with opium, (13) 1989
  two operative cases of stenosis of, (36) 1826—ab
  unsuspected stenosis of, (41) 1283—ab
Pyogenic affections, relations between, (132) 144—ab
Pyorrhea alveolaris, (135) 1364
Pyosalpinx, clinical history of, (15) 1905
  double, (54) 1119
  treatment of, (3) 132—ab
Pyrexia, following childbirth, treated with antistreptococcus serum, (11) 137
  from mechanical intestinal irritation in child, (65) 658

Q

Quacks and quackery, (125) 1031
Quadruplets, case of, (9) 1204
Quarantine, (43) 1761
  of diphtheria and scarlet fever, (44) 1761
  the delirum ferox of American sanitation, (2) 138—ab
Questions, borderland, (88) 1124
Quinin and iron in pneumonia, *1572
  in lobar pneumonia, (49) 1447—ab
  in pernicious malaria, (102) 659
  method of taking, in prophylaxis of malaria, (23) 1829—ab
  peculiar, idiosyncrasy, (61) 1988
Quinquaud's sign, origin of, (70) 500

R

Rabies, destructive action of radium rays on virus of, (118) 228—ab, (34) 2033—ab
Rabies, Pasteur treatment for, administered at patient's home, (59) 74
Rachitis, muscular system in, (40) 500—ab
Rachitis tarda, (82) 1833
Recruit, additional plea for, (20) 1032
Radioactivity, (89) 1209—ab
Radiographs of chest, interpretation of, (110) 358
Radiometry, (90) 1914—ab
Radiophor, (55) 951
Radioscopy, gastric, technic and clinical application of, (27) 1449
Radium, action of, on infectious agents and on infected tissues, (95) 1209—ab
  bromid in rodent ulcer, (4) 358
  emanations and their application, (34) 661
  emanations, experiments with (16) 737—ab, (92) 1286--ab
  experimental research on action of, (67) 1369—ab
  in trachoma, (66) 946
  rays, destructive action of, on virus of rabies, (118) 228--ab
  rays, means to enhance action of, (61) 817—ab
Radius and ulna, backward dislocation of, of long standing, treated by resection, (164) 660
  fracture of head of, (76) 356, (19) 814
  fractures of lower end, with forward displacement of distal fragment, (4) 1115
  fracture of lower extremity, (30) 1826
  fractures of (51) 293, (57) 1363, (36) 1760—ab
  operative treatment of old fractures at lower end of, (30) 1986—ab
Railway coach, bacterial content of, (14) 493—ab
Rats in relation to plague, (2) 947—ab, (10) 1525—ab
Raynaud's disease and ainhum, (90) 947
  disease, with rheumatoid arthritis, (83) 496, (96) 742
Rays, action of, (105) 745
Read, Sir William, Queen Anne's quack oculist, (65) 1762
Receptaculum chyli, thrombosis of, and chylous ascites as complication of cirrhosis of liver, (10) 1690
Rectal alimentation, (8) 217—ab
  cases, plea for more careful examination in, (106) 222
  diseases, employment of mechanical vibration in treatment of, (95) 659—ab
  diseases, radical treatment of certain, under local anesthesia, (96) 659—ab
  surgery, local versus general anesthesia, in, (30) 72—ab
Rectum, abdominoperineal amputation of, (42) 1122—ab
  and colon, anatomy and pathologic conditions of with mechanical methods of treatment, (10) 1276—ab
  bilharzia, (54) 1368—ab
  bloodless resection of, (51) 1362—ab
  examination of, and its value in diagnosis, (9) 354
  fistula of, (47) 424
  foreign body in, (25) 576
  imperforate, with absence of anus, *1305
  office treatment of diseases of, with description of new methods, (7) 1359—ab
  palliative operation on stricture in, (38) 816—ab
  palpation through, in urethritis, (45) 1831—ab
  summary of 25 radical operations on, under local (sterile water) anesthesia, (23) 809—ab
  treatment of carcinoma of, (56) 817—ab, (23) 1117—ab, (43) 1201—ab, (7) 1364
  treatment of malignant strictures of, (1) 1025
Reflexes, aortic, (19) 1027—ab
  vagovisceral, with special reference to the vago-stomach, (5) 1199—ab
Refraction, accurate determination of errors of, without cycloplegia by means of astigmatic charts, (55) 812—ab
  muscle testing in, (102) 1447
Refraction, new instrument, to shorten subjective branch of, and to make it more accurate, (41) 874—ab
  points out of experience in, (111) 75
  slight errors of, and their influence on nervous system, (14) 137
  value of recognition of errors of, in functional diseases of nervous system, (15) 422
Relapsing fever, occurrence in tropics, and relations to tick fever, (4) 421
Remedial preparations, animal, (10) 493—ab
Remedies, restriction of advertising of secret, (82) 1912
Renal diagnosis, (125) 1364
  inadequacy, treatment of, complicated by apparent nephritis, (2) 132—ab
  insufficiency, opotherapic treatment of, (46) 1608
  pelves, lavage of, in treatment of lithemia, pyelitis and certain forms of nephritis, (50) 1761—ab
  pelvis, lavage of, in Bright's disease, (3) 216—ab
Respiration, artificial, (87) 142—ab
Respiratory interchanges, clinical examination of, (32) 949--ab
Resorcin, intoxication from external use of, (50) 1122—ab
Rest, cerebro-psychic, and rest through cerebro-psychic diversion in cure of insanity and insanoid states, (135) 1448
  in treatment of laryngeal and pulmonary tuberculosis, (47) 945—ab
Resuscitation by manipulation of heart of patient apparently dead from shock, (25) 873
Retina, case of detached, (110) 813
  fibrillary edema of, following contusion, (93) 497
  total congenital detachment of, in two brothers, (94) 497
Retinitis, papillo, from iodoform poisoning, (97) 497
Retrospect, respect and prospect, (149) 660
Rheumatism, active treatment of muscular, (23) 1606
  acute articular, (96, 97) 358, (105) 1203, (108) 1203
  atypical, (48) 1446
  formic acid in, (4) 132—ab
  heart sounds in acute, (118) 1125
  of childhood, (121) 497, (78) 1119
  of ocular muscles, (61) 362—ab
  relation of gonorrheal, to seminal vesiculitis and its cure by seminal vesiculotomy, (78) 425
  study of masked, (26) 873, (25) 944, (33) 1028, (19) 1116
  sudden death in acute articular, (19) 76—ab
  treatment of, (162) 660
  treatment of acute articular, (98½) 358
Rhinitis, aspiration treatment of purulent, (76) 953—ab
  carbonic acid gas application in, (60) 1608
Rib, cervical, with resulting gangrene of fingers, (5) 1274
Ricin and abrin experiments, (5) 1694
Rigidity, juvenile, (49) 1450
Roentgen pictures in orthopedic surgery, (79) 79, (46) 1761
  treatment of hypertrophied prostate, (69) 953—ab
  tubes, improved, (99) 1210—ab
Roentgen-ray, action of, in leukemia, (91) 227—ab, (94) 1769—ab, (93) 1014—ab
  action of, on blood, (2) 1904—ab
  application of, (16) 76—ab, (114) 1364
  effect of, on Paget's disease of gluteal region, (55) 134—ab
  in dentistry, *1863
  therapy, present status of, in dermatology, (4) 69—ab
  therapeutic use of (42) 1608
  therapeutic uses of, (14) 133, (71) 1363, (68) 1524, (68) 1832—ab
  treatment of some neuralgias by, (2) 228—ab
Roentgen-ray, use of, in diagnosis of foreign bodies in cranium, (144) 497
Roentgenology, why should, be practiced only by physician, (40) 289
Rotunda hospital, clinical report of, (22) 499—ab
Royal college of surgeons of Edinburgh, its early connection with medical teaching, (5) 577
Rubber gloves, permeability to bacteria of surgeon's, (40) 1693—ab
Rubeola and double exanthemata, (103) 143—ab
Russo-Japanese naval war 1904-05, experiences during, (104) 1908

S

Saccharin, influence of, on digestive enzymes, *844
Sachs' lamp for transillumination of eye, (117) 497
Sacrum, congenital, tumors of, (52) 1612
Saddle-nose, transplantation of bone for relief of, *1481
Safety-pin safely passed by child of eleven months, *1655
St. Louis water supply, symposium on, (82) 426
Sajous, internal secretions and principles of medicine, (99) 74

  surgical aspects of, (24) 1909
  treatment of, (126) 947, (10) 1521—ab, (47) 1761, (65) 1988
  treatment of, in small towns and rural communities, (87) 1120
  treatment of, with castor oil, (34) 944
  two cases, with acute general peritonitis, (35) 423
  two cases, with perforation and operation, *1494
  ulcer, surgery of perforated, (116) 1120
Typhus baccilus, (78) 1613
  bacillus and bacillus fecalis alcaligenes, (85) 1453

U

Ulcer, acute gastric and duodenal, (33) 1830
  chronic of stomach, and first portion of duodenum, *1211
  dangerous complications in starvation treatment of peptic, (97) 665—ab
  death from hemorrhage from duodenal, two weeks after extensive burn, (87) 659
  duodenal, by one of its victims, (10) 1604
  duodenal, treated by gastroenterostomy, (2) 498
  gastric and duodenal, (31) 1986
  leg, treatment of, (99) 1524
  perforating duodenal, (7) 742
  perforation of duodenum; diagnosis and treatment, (17) 1825
  peptic, with fistulas and closure of gastroenteroanastomosis, (66) 1612
  radium bromid in treatment of rodent, (4) 358
Ulcer, Zambest, (23) 1205
Ulceration, ano-rectal, (6) 1032—ab
Ulcerations, value of early diagnosis, in anorectal region, (38) 1906
Ulcers, ambulant treatment of, (87) 953
  ambulant, treatment of leg, (30) 662—ab
  boric acid treatment of varicose, (79) 664—ab
Ulna, compound dislocation with fracture of left, *1954
  fractures and dislocations of, (5) 288, (3) 353—ab
Ultramicroscope researches, (121) 143—ab
Uncinaria and other intestinal parasites in West Indies, (24) 1121
Uncinariasis ankylostomiasis or, *588
  further remarks on mode of infection in, *1142
  in California, (38) 657
Unconsciousness, new phase of alcoholic, (78) 1031
Union, delayed and ununited fractures, *1319
United States navy, medical corps and some details respecting its past and present, (41) 73
Unity, peace and concord, *365
Urachus, patent, (1) 1358—ab
Urea, pharmacology of diethyloxyacetyl, *1917
  retention of, in Bright's disease, (34) 815—ab
Ureter, constriction of, (4) 222
  hernia of, (55) 293
  three cases of repair of injury to, (58) 355
  treatment of operative injury of, (25) 1990—ab
Ureteral and renal diseases, newer methods in use in diagnosis of, (78) 496
  calculus, differential diagnosis of from pain, (93) 222
  catheterization of, (93) 1364
  congenital dilatation of, with hydronephrosis, (27) 1282
  injuries of, during gynecologic operations, (138) 1448
  pathogenesis, symptomatology and diagnosis of deformities in, in women, (41) 950—ab
  stones, diagnosis of, (93) 810—ab
  therapeutic catheterization of, (93) 142—ab
Urethra, diagnosis and treatment of stricture of, (128) 947
  electrolysis in treatment of stricture of, (47) 1830
  forward displacement of, (36) 1121
  inflammatory stricture of posterior, (21) 1990
  injections, technic of, (76) 226
  injuries and strictures of, (80) 1369—ab
  lymphoid tissue in mucosa of male, (28) 743
  reflex irritations from lesions in male, (20) 1360
  stricture of male, (34) 576
  stricture of, tunneled and grooved sound and catheter for dilatation of, (18) 575
  strictures of, their pathology and treatment, (11) 1690
Urethritis, causes retarding recovery of gonorrheal, (48) 1761
  chronic, (126) 659
  non-gonorrheal, (14) 169—ab
  rectal palpation in diagnosis and treatment of acute gonorrheal, (24) 223—ab
  treatment of acute gonorrheal, (52) 1693
  treatment of chronic, (29) 815, (49) 1761
  treatment of conditions resulting from chronic anterior, (26) 1986—ab
Uric-acid, clinical method for quantitative estimation of, in urine, (5) 427—ab
  diathesis in children, (137) 497
  elimination of endogenous, in chronic gout, (3) 736
  freedom from, and how to obtain it, (8) 808
  medical treatment of excessive, in urine, (6) 808—ab
  rapid and simple process for estimation of, (11) 1695—ab
  rational treatment for its elimination in light of recent research, (10) 358
Uricemia, food factor in, (14) 873—ab
Urinary, analysis, centrifugal, (22) 2031
  tract, early diagnosis of surgical diseases of, *519
  tract localization of chronic suppurations of, (28) 809—ab
  tract, newer aids to diagnosis in diseases of, *18
Urine, after anesthesia, (60) 74
  amylolytic action of, (20) 223
  and exudates, to stain sediment of, (76) 1529—ab
  [illegible] 1364
  [illegible] (120) 745
  [illegible] for clinical purposes, tests for electric conductivity of, (17) 575
  attempt to utilize electric conductivity of, for clinical purposes, (78) 1279—ab
  carbohydrates of, in health and in disease, (65) 74
  conditions influencing acidity and alkalinity of, (83) 1529
  detection of minute traces of sugar in, (64) 425
  determination of ammonia and carbonic acid in, (70) 1284
  determination of diacetic acid in, (67) 953—ab
  determination of indican in, (75) 1124—ab
  different albumins of, detection and clinical significance, (118) 1448
  endo-vesical separation of, (44) 1830
  freezing point of, in infectious diseases, (70) 1700—ab
  freezing points of blood and, in pneumonia, *894
  importance of correct interpretation of source of pathologic elements in, (79) 1524
  incontinence with neurasthenic symptoms, and its treatment by isolated induction shock, (25) 1985—ab
  in febrile diseases, (81) 1208—ab
  influence of changes in circulation on composition of, (65) 1284—ab
  in gastrointestinal fermentation, (92) 947
  in secondary syphilis and under mercurial treatment, (66) 141—ab
  intravesical separation of, from kidneys, (23) 223—ab
  new morphologic element in, (123) 1126—ab
  preservation of, (17) 134—ab
  separation within bladder of, from each kidney, (24, 37) 139—ab
  significance of pathologic elements in, with description of best methods of ascertaining their source, (40) 1118
  suppression of, after diphtheria, (102) 1031
  treatment of incontinence of, in children, (7) 133—ab
Urogenital system, rare deformity in girl, (92) 1124
Urology, report of IX congress of, (26) 1610
  report of French congress of, 1904, (22) 139
Urotropin and helmitol, (28) 1990
Urticaria, study of gastric contents in, (2) 871—ab
Uter[illegible] 184
Uter[illegible] of [illegible] 4
  ab
  acute inversion and prolapse of, (84) 813
  and bladder, fibromyoma of, with calcification and ossification, (41) 1446
  biseptum, (111) 1203
  blood examinations in women ill with pelvic diseases, especially myoma of, (84) 745—ab
  cancer of, (90) 1828
  can incipient glandular carcinoma of, be cured by curetting? (293—ab
  carcinoma, involvement of urinary passages, (87) 1124
  conservative treatment of myoma, (102) 1286—ab
  cyst of body, (62) 1694
  diagnosis and treatment of cancer of, (1) 1280—ab
  diagnosis and treatment of laceration of vaginal portion of, and fornix vaginæ, (43) 1119
Uterus, diagnosis and treatment of rupture of, (57) 1029
  early diagnosis of cancer of body of, (31) 494
  experimental study of contractions of, (61) 225—ab
  fibroid tumors of, surgical treatment of, (31) 72—ab
  foreign bodies in, (53) 225—ab
  fourth report of results of bi-inguinal operation for retroversion, *1546
  hysterectomy for sloughing degenerated fibroma of (56) 1119
  improved curettage of, (30) 499
  infantile, and treatment with new operation for anteflexion and stenosis of internal os, (38) 944—ab
  influence of pregnancy on, (83) 881
  inguinal hernia of, (35) 224--ab
  innocent fibromyoma of, *1238
  inversion of, (52) 290, (120) 666, (139) 877, (30) 1366, (76) 1908, *1920
  malformations of, (32) 2032
  malignancy in, myomata of, (50) 1693
  migratory, fibroids of, (40) 355
  mortality in operations on fibroids of, (40) 944—ab, (41) 1361—ab
  myoma of, (90) 358, (60) 1368
  new instrument for ventrofixation of, (43) 1611
  perfected surgical treatment of fibroids of, (38) 1028
  plea for evacuation of, in unrelieved cases of puerperal eclampsia, (7) 1762
  position of bladder in fibroid of, (10) 655
  pregnancy in one cornu of bicornate; complicated labor, (30) 74
  prolapse of, and its treatment, (103) 427
  psammoma bodies in carcinomatous, (43) 292
  radical cure of cancer of, (127) 813, (59) 879
  radical vaginal method of removing, fibromata of, (91) 1994
  recent methods of correcting retrodisplacements, (95) 426
  red degeneration of a fibromyoma of, (18) 1694
  report and description of myoma of, and three cases of ovarian dermoid tumor, (18) 223
  retrodisplacements of, operative treatment of, with new operation; intramural transplantation of round ligaments, (51) 1987—ab
  retroverted, (9) 1759—ab, (49) 2034—ab
  sarcoma of (46) 1367—ab, (62) 1832—ab
  spontaneous laceration of pregnant, septic infected diverticulum in, (46) 292
  steam cauterization, (83) 954—ab
  study of results of abdominal hysterectomy for fibroids, (31) 1446—ab
  surgical treatment of posterior malpositions of, (74) 741
  total extirpation of pregnant, (100) 1124
  transplantation of round ligaments for correction of backward displacements (14) 1521—ab
  treatment of cancer of, (96) 818—ab
  treatment of fibroids of (70) 875
  treatment of myoma of, (88) 1834—ab
  treatment of retrodisplacement, clinical study based on records of 653 cases, (58) 74
  varying tonus of, in response to intrauterine stimuli, (47) 1911—ab
  ventrosuspension and fixation of, (56) 1827
  wandering or aberrant, fibromyomata, *10
  when should myoma of, be operated on? (97) 74

V

Vaccination, erythema multiforme following, *852
  Haffkine's anticholera and antiplague, (34) 1034—ab

- Vaccination, treatment and conditions of infant which preclude its being done, (35) 1765—ab
  - typhoid and plague, (34) 1121—ab
- Vaccine, acute illness following inoculation with antityphoid, (21) 1204
- Vaccines, general principles of therapeutic inoculation of bacterial, as applied to treatment of tuberculous infection, (9) 2032
- Vaccinia, pathology and etiology of human, (4) 1689
- Vacuum cleaning applied to operative wounds, (37) 878-ab
- Vagina and uterus, congenital absence of, (79) 74
  - and uterus, prolapse, treatment of, (44) 1034
  - total absence of, and its surgical treatment, (101) 1031
- Vaginismus, treatment of, (54) 880—ab
- Valgus, midtarsal, or knock ankle, (25) 1277
  - peroneal resection as means of correction in rigid, (29) 657—ab
- Valvotomy, new and simple method of perforating rectal, (22) 1445—ab
- Valvular disease, importance of early recognition of, in children, (12) 575—ab
- Varicella, accompanying herpes zoster, (67) 658—ab
  - gangrenosa, (24) 219
- Varices, origin of, (127) 143—ab
  - pathogenesis of, (38) 529—ab (30) 743
- Variola and varicella differentiation, (93) 745
  - observations and statistics of cases handled by health department of St. Louis for years 1903 04, (20) 944—ab
- Varix, congenital, of superficial epigastric vein and its anastomoses, (24) 1445
- Vasomotor action, pathologic variations of physiologic, with reference to malarial paroxysmal neuroses, (13) 743
- Vault, compound fracture of, with loss of brain substance, *1801
- Vegetarianism and its effects on teeth, (12) 1120
- Vein, considerations regarding ligature of internal jugular, for ear disease, (34) 1205
- Veins, ligation of ovarian and hypogastric, in puerperal pyemia, (55)1911—ab
  - new method of extracting internal saphenous and similar, in varicose conditions, (30) 738—ab
  - suture of, review of subject, (79) 876
- Venereal disease, self-protection against, (64) 431
  - diseases, danger of, and prophylaxis, (82) 1762
  - diseases, treatment of, in the services, (8) 1032
- Venoms, action of, of different species of poisonous snakes on nervous system,(16) 1281
- Ventricle, suture of left, for bullet wound, (60) 1612
- Ventrofixation, (85) 1124—ab
  - and disturbances later, (93) 1125—ab
- Vernal catarrh, (99) 497—ab
- Vertebræ, fracture of first, second and third dorsal, (62) 1030—ab
  - resemblance between caries of, and lumbothoracic syringomyelia and location within spinal cord of fibers for sensations of pain and temperature, (113) 1280
- Vertigo, ocular, of interest to general practitioner, (26) 1027
  - of aural causation, (21) 1276
- Vesical calculus, (138) 497
- Vials, burette, (40) 879—ab
- Vibration and digestion, mechanical, (99) 1031
  - employment of mechanical, in influence on Faradization, (93) 226
  - treatment of rectal diseases, (95) 659—ab
  - mechanical and stimulation, (119) 813
  - transposition of, and other autopsy findings, (66) 1119
- Viscera, postoperative prolapse of abdominal, (46) 1283—ab
  - transposition, hereditary, (53) 1119—ab
- Visual acuteness, new test for, (15) 947
- Vital values, (35) 73
- Volkmann's contracture treated by shortening radius and ulna, (15) 1610—ab
- Volvulus, combined and hernia through a recent mesenteric slit, (38) 738
- Vomer, sarcoma of, with involvement of adjacent structures and metastasis in cranium, (51) 875
- Vomiting, astigmatism cause of, in school children, (14) 809—ab
  - periodical, of children, (86) 817
  - pernicious, of pregnancy, (87) 741—ab
  - postoperative, (84) 741
- Vulva, epithelioma of, (57) 875, (96) 1120
  - histology of desmoid, tumors of, (63) 1368
- Vulvitis, pathology of, (58) 743

W

- Waking suggestion same as hypnosis, (79) 953
- Walking, equipment for treating disturbances in, (50) 816
- Warner - Ziemann - Romanowsky, staining method, (94) 741
- Water analysis, report of committee on standard methods of, (58) 813—ab
  - bactericidal power of Nesfield's method of purifying drinking, and sterilizing, for surgical purposes, (24) 877
  - chemical phases of a, softening problem, (61) 812
  - chemical process of sterilizing, for drinking purposes for use in field and home, (22) 660
  - drinking, therapeutic use of, and some dangers,(51)290-ab
  - injections of sea, (23) 1033-ab
  - sterile, as a local anesthetic, (94) 659
  - supply in ships from its beginning to present time, *1846
  - supply, recent progress in matters of, and sewage disposal, *1059
- Water supply, relative value of various methods of determining sanitary quality of, (85) 496
- Weighing, necessity for constant, in antifat and forced feeding cures, (97) 1453
- Whitman method of treatment of fracture of neck of femur, (11) 1443
- Whooping-cough, (32) 1277
  - antitussin in treatment of, (98) 745
- Widal's reaction for typhoid fever, (32) 289
- Will, defects of, from medical standpoint, *1309
- Wine and poets, critical study of poet's devotion to god of wine, (79) 1031
- Wines, rational use of, in health and disease, (94) 1524
- Wirsung's duct, ligature of, (74) 1699
- Women and children, diseases of, (75) 496, (122) 1448, (82) 1828
  - conservative treatment of pelvic diseases in, (33) 576
  - investigations of energy of life functions in, after extirpation of uterus, with and without adnexa, (105) 427
  - pathologic desires to urinate and cystitis in, (98) (1125-ab
  - pelvic infections in, (67) 1203
  - plea for more careful examination of, by general practitioner, (21) 1985
  - sexual frigidity in, (43½) 944.
  - sterilization of, (42) 1611
  - what advice should be given to, with malposition of uterus, (5) 217—ab
- Wood alcohol, poisoning by, (16) 218—ab
- Word-blindness due to lesion in right cerebral hemisphere in right-handed man, (43) 1907
- Work as therapeutic means, (38) 662—ab
- Workman, food of Parisian, (38) 1991—ab
- Wounded, arrangements for treatment of, in action on board, (3) 813
  - collection and distribution of, in modern cruiser engagement, (4) 813
  - first aid to, in naval battles, (46) 1277
- Wounds, antitetanic serum in gunshot, (35) 576
  - experimental inquiry into infection of operative, (6) 498
  - influence of pneumococci on healing of, (17) 1027—ab
  - leading cases of, inflicted in Japan-Russia war, (82) 80—ab
  - open treatment of, and transplantation, (66) 1912
  - penetrating, of abdomen, *1048
  - practical novel and rational treatment of gaping, (59) 1694
  - suggestions in treatment of, (27) 576
  - treatment of, and contusions of pelvic outlet produced during labor, (81) 74
  - treatment of infected or suspicious, (47) 816—ab
  - treatment of infected, with a phenol product, (50) 73—ab
  - ultra-violet light treatment of, (94) 1454—ab
- Wounds, vacuum cleaning applied to operative, (37) 878—ab
- Wrestlers, observations on, (78) 295—ab

X

- Xanthoma, diabetic, case of, (30) 1830
- Xerostoma, (53) 945
- Xiphopagus, delivery and separation of, (94) 1125—ab
- X-light, notes on, (111) 358
- X-radiations, adjustment of, for various physiologic effects, (24) 1759
- X-ray, effect of, on pregnancy, (108) 358
  - in bone tuberculosis,(51) 740-ab
  - in malignant disease of orbit, (1) 132—ab
  - in tubercular adenitis, (53) 290—ab
  - present state of knowledge concerning therapeutic value of, (64) 1278—ab
  - treatment of hypertrophied prostate, (133) 746—ab
  - tube, safety, (23) 354, (25) 1445—ab
  - twin, representation, and reflecting stereoscope,(25) 1282
  - uses and abuses of, (70) 1363
  - value of, in treatment of tuberculosis, (102) 358
- X-rays, action of, on tissues, (21) 359—ab
  - in recurring leukemia and Banti's disease, (84) 362—ab
  - in treatment of cancer, (19) 1763—ab
  - leucocythemia treated by, with record of four cases, (5) 359—ab
  - treatment of ringworm of scalp by, (6) 358
  - use, in skin affections, (21) 133

Y

- Yaws nodule, pathology of, (25) 1121
- Yeast, action, in tuberculosis and influence on opsonic index, (10) 75—ab
  - fungi, pathogenic influence of, (83) 1994
- Yellow-fever blood, preliminary report on cells found in, with reference to etiologic and diagnostic significance, *915
  - data, (100) 1364
  - difficulties in diagnosis of, as seen on Isthmus, (105) 1908
  - in Cuba, (1) 1823—ab
  - lessons to be learned from present outbreak, in Louisiana, *1079
  - lessons to be learned from present epidemic of, (60) 1363—ab
  - malarial origin and propagation of, (32) 809—ab
  - pathology of, (33) 1826
  - prophylaxis and treatment of, (31) 809—ab
  - some observations on treatment, *1620
  - third anniversary of eradication of, (100) 364—ab
  - treatment of, (34) 1826—ab

Z

- Zomotherapy, demineralization and, in tuberculosis (72) 817
  - in tuberculosis, (20) 428—ab

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

In this Index are the names of the authors of articles which have appeared in The Journal of the American Medical Association and of articles which have been listed from week to week in the department of Current Medical Literature as having appeared in other journals. Thus it practically includes the names of all who have published articles in the leading journals of the world during the past six months. The * preceding the page reference indicates that the article appeared in full in The Journal. The numbers in parentheses indicate the numbered paragraphs on the page referred to. The numbers not in parentheses indicate pages.
